7	87 **Fr** [223.02]	88 **Ra** [226.03]	103 **Lr** [262.11]	104 **Rf** [267.1]	105 **Db** [268.1]	106 **Sg** [269.1]	107 **Bh** [270.1]	108 **Hs** [269.1]	109 **Mt** [278.2]	110 **Ds** [281.2]	111 **Rg** [282.2]	112 **Cn** [285.2]	113 **Nh** [286.2]	114 **Fl** [289.2]	115 **Mc** [289.2]	116 **Lv** [293.2]	117 **Ts** [293.2]	118 **Og** [294.2]

Lanthanide series	57 **La** 138.9055	58 **Ce** 140.116	59 **Pr** 140.90766	60 **Nd** 144.24	61 **Pm** [145]	62 **Sm** 150.36	63 **Eu** 151.964	64 **Gd** 157.25	65 **Tb** 158.92534	66 **Dy** 162.50	67 **Ho** 164.93033	68 **Er** 167.259	69 **Tm** 168.93422	70 **Yb** 173.04
Actinide series	89 **Ac** [227.03]	90 **Th** 232.0377	91 **Pa** 231.03588	92 **U** 238.02891	93 **Np** [237.05]	94 **Pu** [244.06]	95 **Am** [243.06]	96 **Cm** [247.07]	97 **Bk** [247.07]	98 **Cf** [251.08]	99 **Es** [252.08]	100 **Fm** [257.10]	101 **Md** [258.10]	102 **No** [259.10]

[a] The labels on top (1A, 2A, etc.) are common American usage. The labels below these (1, 2, etc.) are those recommended by the International Union of Pure and Applied Chemistry (IUPAC).

Values in brackets are the atomic weights of the longest-lived or most important isotope of radioactive elements.

Further information is available at http://www.webelements.com

List of Elements with Their Symbols and Atomic Weights

Element	Symbol	Atomic Number	Atomic Weight
Actinium	Ac	89	227.03[a]
Aluminum	Al	13	26.981538
Americium	Am	95	243.06[a]
Antimony	Sb	51	121.760
Argon	Ar	18	39.948
Arsenic	As	33	74.92160
Astatine	At	85	209.99[a]
Barium	Ba	56	137.327
Berkelium	Bk	97	247.07[a]
Beryllium	Be	4	9.012183
Bismuth	Bi	83	208.98038
Bohrium	Bh	107	270.1[a]
Boron	B	5	10.81
Bromine	Br	35	79.904
Cadmium	Cd	48	112.414
Calcium	Ca	20	40.078
Californium	Cf	98	251.08[a]
Carbon	C	6	12.0107
Cerium	Ce	58	140.116
Cesium	Cs	55	132.905452
Chlorine	Cl	17	35.453
Chromium	Cr	24	51.9961
Cobalt	Co	27	58.933194
Copernicium	Cn	112	285.2[a]
Copper	Cu	29	63.546
Curium	Cm	96	247.07[a]
Darmstadtium	Ds	110	281.2[a]
Dubnium	Db	105	268.1[a]
Dysprosium	Dy	66	162.50
Einsteinium	Es	99	252.08[a]
Erbium	Er	68	167.259
Europium	Eu	63	151.964
Fermium	Fm	100	257.10[a]
Flerovium	Fl	114	289.2[a]
Fluorine	F	9	18.9984016
Francium	Fr	87	223.02[a]
Gadolinium	Gd	64	157.25
Gallium	Ga	31	69.723
Germanium	Ge	32	72.64
Gold	Au	79	196.966569
Hafnium	Hf	72	178.49
Hassium	Hs	108	269.1[a]
Helium	He	2	4.002602
Holmium	Ho	67	164.93033
Hydrogen	H	1	1.00794
Indium	In	49	114.818
Iodine	I	53	126.90447
Iridium	Ir	77	192.217
Iron	Fe	26	55.845
Krypton	Kr	36	83.80
Lanthanum	La	57	138.9055
Lawrencium	Lr	103	262.11[a]
Lead	Pb	82	207.2
Lithium	Li	3	6.941
Livermorium	Lv	116	293[a]
Lutetium	Lu	71	174.967
Magnesium	Mg	12	24.3050
Manganese	Mn	25	54.938044
Meitnerium	Mt	109	278.2[a]
Mendelevium	Md	101	258.10[a]
Mercury	Hg	80	200.59
Molybdenum	Mo	42	95.95
Moscovium	Mc	115	289.2[a]
Neodymium	Nd	60	144.24
Neon	Ne	10	20.1797
Neptunium	Np	93	237.05[a]
Nickel	Ni	28	58.6934
Nihonium	Nh	113	286.2[a]
Niobium	Nb	41	92.90637
Nitrogen	N	7	14.0067
Nobelium	No	102	259.10[a]
Oganesson	Og	118	294.2[a]
Osmium	Os	76	190.23
Oxygen	O	8	15.9994
Palladium	Pd	46	106.42
Phosphorus	P	15	30.973762
Platinum	Pt	78	195.078
Plutonium	Pu	94	244.06[a]
Polonium	Po	84	208.98[a]
Potassium	K	19	39.0983
Praseodymium	Pr	59	140.90766
Promethium	Pm	61	145[a]
Protactinium	Pa	91	231.03588
Radium	Ra	88	226.03[a]
Radon	Rn	86	222.02[a]
Rhenium	Re	75	186.207[a]
Rhodium	Rh	45	102.90550
Roentgenium	Rg	111	282.2[a]
Rubidium	Rb	37	85.4678
Ruthenium	Ru	44	101.07
Rutherfordium	Rf	104	267.1[a]
Samarium	Sm	62	150.36
Scandium	Sc	21	44.955908
Seaborgium	Sg	106	269.1[a]
Selenium	Se	34	78.97
Silicon	Si	14	28.0855
Silver	Ag	47	107.8682
Sodium	Na	11	22.989770
Strontium	Sr	38	87.62
Sulfur	S	16	32.065
Tantalum	Ta	73	180.9479
Technetium	Tc	43	98[a]
Tellurium	Te	52	127.60
Tennessine	Ts	117	293.2[a]
Terbium	Tb	65	158.92534
Thallium	Tl	81	204.3833
Thorium	Th	90	232.0377
Thulium	Tm	69	168.93422
Tin	Sn	50	118.710
Titanium	Ti	22	47.867
Tungsten	W	74	183.84
Uranium	U	92	238.02891
Vanadium	V	23	50.9415
Xenon	Xe	54	131.293
Ytterbium	Yb	70	173.04
Yttrium	Y	39	88.90584
Zinc	Zn	30	65.39
Zirconium	Zr	40	91.224

[a] Mass of longest-lived or most important isotope.

Pearson's Commitment to Diversity, Equity, and Inclusion

Pearson is dedicated to creating bias-free content that reflects the diversity, depth, and breadth of all learners' lived experiences.

We embrace the many dimensions of diversity, including but not limited to race, ethnicity, gender, sex, sexual orientation, socioeconomic status, ability, age, and religious or political beliefs.

Education is a powerful force for equity and change in our world. It has the potential to deliver opportunities that improve lives and enable economic mobility. As we work with authors to create content for every product and service, we acknowledge our responsibility to demonstrate inclusivity and incorporate diverse scholarship so that everyone can achieve their potential through learning. As the world's leading learning company, we have a duty to help drive change and live up to our purpose to help more people create a better life for themselves and to create a better world.

Our ambition is to purposefully contribute to a world where:

- Everyone has an equitable and lifelong opportunity to succeed through learning.
- Our educational content accurately reflects the histories and lived experiences of the learners we serve.
- Our educational products and services are inclusive and represent the rich diversity of learners.
- Our educational content prompts deeper discussions with students and motivates them to expand their own learning (and worldview).

Accessibility

We are also committed to providing products that are fully accessible to all learners. As per Pearson's guidelines for accessible educational Web media, we test and retest the capabilities of our products against the highest standards for every release, following the WCAG guidelines in developing new products for copyright year 2022 and beyond.

You can learn more about Pearson's commitment to accessibility at **https://www.pearson.com/us/accessibility.html**

Contact Us

While we work hard to present unbiased, fully accessible content, we want to hear from you about any concerns or needs with this Pearson product so that we can investigate and address them.

Please contact us with concerns about any potential bias at **https://www.pearson.com/report-bias.html.**

For accessibility-related issues, such as using assistive technology with Pearson products, alternative text requests, or accessibility documentation, email the Pearson Disability Support team at **disability.support@pearson.com**

To our students,
whose enthusiasm and curiosity
have often inspired us,
and whose questions and suggestions
have sometimes taught us.

BRIEF CONTENTS

PREFACE xxi

1 Introduction: Matter, Energy, and Measurement 1
2 Atoms, Molecules, and Ions 41
3 Chemical Reactions and Reaction Stoichiometry 85
4 Reactions in Aqueous Solution 119
5 Thermochemistry 161
6 Electronic Structure of Atoms 211
7 Periodic Properties of the Elements 255
8 Basic Concepts of Chemical Bonding 297
9 Molecular Geometry and Bonding Theories 335
10 Gases 391
11 Liquids and Intermolecular Forces 431
12 Solids and Modern Materials 469
13 Properties of Solutions 521
14 Chemical Kinetics 565
15 Chemical Equilibrium 621
16 Acid–Base Equilibria 661
17 Aqueous Equilibria: Buffers, Titrations, and Solubility 713
18 Chemistry of the Environment 763
19 Chemical Thermodynamics 799
20 Electrochemistry 839
21 Nuclear Chemistry 891
22 Chemistry of the Nonmetals 933
23 Transition Metals and Coordination Chemistry 977
24 The Chemistry of Life: Organic and Biological Chemistry 1021

APPENDICES

A Mathematical Operations 1069
B Properties of Water 1076
C Thermodynamic Quantities for Selected Substances at 298.15 K (25 °C) 1077
D Aqueous Equilibrium Constants 1081
E Standard Reduction Potentials at 25 °C 1083

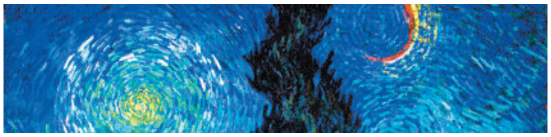
CONTENTS

PREFACE **xxi**



1 Introduction: Matter, Energy, and Measurement 1

1.1 The Study of Chemistry **2**
The Atomic and Molecular Perspective of Chemistry 2 Why Study Chemistry? 3

1.2 Classifications of Matter **4**
States of Matter 4 Pure Substances 5 Elements 6 Compounds 6 Mixtures 8

1.3 Properties of Matter **10**
Types of Properties of Substances 10 Physical and Chemical Changes 10 Separation of Mixtures 11

1.4 The Nature of Energy **13**
Work and Heat 13 Kinetic Energy and Potential Energy 13

1.5 Units of Measurement **16**
The Metric System and SI Units 16 Length and Mass 18 Temperature 18 Derived SI Units 19 Units of Energy 21

1.6 Uncertainty in Measurement and Significant Figures **23**
Exact and Inexact Numbers 23 Precision and Accuracy 23 Significant Figures 23 Significant Figures in Calculations 25

1.7 Dimensional Analysis **28**
Conversion Factors 28 Using Two or More Conversion Factors 29 Calculations in Which a Conversion Factor Is Raised to a Power 30

Chapter Summary and Key Terms **33**
Key Equations **33** Exam Prep **33** Exercises **34**
Additional Exercises **39**

Chemistry and Sustainability An Introduction 15
A Closer Look The Scientific Method 22
Strategies for Success Estimating Answers 28
Strategies for Success The Importance of Practice—and How to Use the Book 32

2 Atoms, Molecules, and Ions 41

2.1 The Atomic Theory of Matter **42**

2.2 The Discovery of Atomic Structure **43**
Cathode Rays and Electrons 43 Radioactivity 45 The Nuclear Model of the Atom 46

2.3 The Modern View of Atomic Structure **48**
Atomic Numbers, Mass Numbers, and Isotopes 49

2.4 Atomic Weights **51**
The Atomic Mass Scale 51 Atomic Weight 51

2.5 The Periodic Table **53**

2.6 Molecules and Molecular Compounds **56**
Molecules and Chemical Formulas 56 Molecular and Empirical Formulas 57 Picturing Molecules 57

2.7 Ions and Ionic Compounds **59**
Predicting Ionic Charges 60 Ionic Compounds 61

2.8 Naming Inorganic Compounds **63**
Names and Formulas of Ionic Compounds 63 Names and Formulas of Inorganic Acids 67 Names and Formulas of Binary Molecular Compounds 68

2.9 Some Simple Organic Compounds **69**
Alkanes 70 Isomers 70 Nomenclature of Alkanes 71 Alcohols and Carboxylic Acids 73

Chapter Summary and Key Terms **76**
Key Equations **77** Exam Prep **77** Exercises **77**
Additional Exercises **83**

A Closer Look Basic Forces 49
A Closer Look The Mass Spectrometer 52
Chemistry and Life Elements Required by Living Organisms 62
Strategies for Success How to Take a Test 75

3 Chemical Reactions and Reaction Stoichiometry 85

3.1 Chemical Equations 86
Balancing Equations 86 A Step-by-Step Example of Balancing a Chemical Equation 87 Indicating the States of Reactants and Products 89

3.2 Simple Patterns of Chemical Reactivity 90
Combination and Decomposition Reactions 90 Combustion Reactions 92

3.3 Formula Weights 93
Formula and Molecular Weights 93 Percentage Composition from Chemical Formulas 94

3.4 Avogadro's Number and the Mole 95
Molar Mass 96 Interconverting Masses, Moles and Numbers of Particles 98

3.5 Empirical Formulas from Analyses 99
Molecular Formulas from Empirical Formulas 100 Combustion Analysis 101

3.6 Quantitative Information from Balanced Equations 103

3.7 Limiting Reactants 106
Theoretical and Percent Yields 108

Chapter Summary and Key Terms 109
Key Equations 110 Exam Prep 110 Exercises 111
Additional Exercises 117 Design an Experiment 118

Chemistry and Sustainability Cement and CO_2 Emissions 91

Strategies for Success Problem Solving 95

Strategies for Success Design an Experiment 109

4 Reactions in Aqueous Solution 119

4.1 General Properties of Aqueous Solutions 120
Electrolytes and Nonelectrolytes 120 How Compounds Dissolve in Water 121 Strong and Weak Electrolytes 122

4.2 Precipitation Reactions 123
Solubility Guidelines for Ionic Compounds 124 Exchange (Metathesis) Reactions 125 Ionic Equations and Spectator Ions 126

4.3 Acids, Bases, and Neutralization Reactions 128
Acids 128 Bases 129 Strong and Weak Acids and Bases 129 Identifying Strong and Weak Electrolytes 130 Neutralization Reactions and Salts 131 Neutralization Reactions with Gas Formation 132

4.4 Oxidation–Reduction Reactions 135
Oxidation and Reduction 135 Oxidation Numbers 136 Oxidation of Metals by Acids and Salts 138 The Activity Series 139

4.5 Concentrations of Solutions 142
Molarity 142 Expressing the Concentration of an Electrolyte 143 Interconverting Molarity, Moles, and Volume 144 Dilution 145

4.6 Solution Stoichiometry and Chemical Analysis 147
Titrations 148

Chapter Summary and Key Terms 152
Key Equations 153 Exam Prep 153
Exercises 154 Additional Exercises 158
Design an Experiment 160

Chemistry and Life Stomach Acids and Antacids 134

Chemistry and Sustainability Acid Rain 135

Strategies for Success Analyzing Chemical Reactions 142

5 Thermochemistry 161

5.1 The Nature of Chemical Energy 162

5.2 The First Law of Thermodynamics 164
System and Surroundings 165 Internal Energy 165 Relating ΔE to Heat and Work 166 Endothermic and Exothermic Processes 168 State Functions 168

5.3 Enthalpy 170
Pressure–Volume Work 171 Enthalpy Change and Heat 172

5.4 Enthalpies of Reaction 174

5.5 Calorimetry 177
Heat Capacity and Specific Heat 177 Constant-Pressure Calorimetry 178 Bomb Calorimetry (Constant-Volume Calorimetry) 180

5.6 Hess's Law 182

5.7 Enthalpies of Formation 184
Using Enthalpies of Formation to Calculate Enthalpies of Reaction 186

5.8 Bond Enthalpies 188

Bond Enthalpies and the Enthalpies of Reactions 190

5.9 Foods and Fuels 192

Foods 192 Fuels 194 Other Energy Sources 195

Chapter Summary and Key Terms **198** Key Equations **199** Exam Prep **199** Exercises **201** Additional Exercises **209** Design an Experiment **210**

A Closer Look Energy, Enthalpy, and *P–V* Work 173

A Closer Look Using Enthalpy as a Guide 176

Chemistry and Life The Regulation of Body Temperature 181

Chemistry and Sustainability The Scientific and Political Challenges of Biofuels 196

6 Electronic Structure of Atoms 211

6.1 The Wave Nature of Light 212

6.2 Quantized Energy and Photons 214

Hot Objects and the Quantization of Energy 214
The Photoelectric Effect and Photons 215

6.3 Line Spectra and the Bohr Model 217

Line Spectra 217 Bohr's Model 218 The Energy States of the Hydrogen Atom 219 Limitations of the Bohr Model 222

6.4 The Wave Behavior of Matter 222

The Uncertainty Principle 223

6.5 Quantum Mechanics and Atomic Orbitals 225

Orbitals and Quantum Numbers 226

6.6 Representations of Orbitals 229

The *s* Orbitals 229 The *p* Orbitals 232 The *d* and *f* Orbitals 232

6.7 Many-Electron Atoms 234

Orbitals and Their Energies 234 Electron Spin and the Pauli Exclusion Principle 234

6.8 Electron Configurations 235

Hund's Rule 237 Condensed Electron Configurations 238 Transition Metals 239 The Lanthanides and Actinides 240

6.9 Electron Configurations and the Periodic Table 240

Anomalous Electron Configurations 243

Chapter Summary and Key Terms **244** Key Equations **246** Exam Prep **246** Exercises **247** Additional Exercises **252** Design an Experiment **254**

A Closer Look Measurement and the Uncertainty Principle 224

A Closer Look Schrödinger's Cat and Quantum Computing 227

Chemistry and Life Nuclear Spin and Magnetic Resonance Imaging 236

7 Periodic Properties of the Elements 255

7.1 Development of the Periodic Table 256

7.2 Effective Nuclear Charge 257

7.3 Sizes of Atoms and Ions 261

Periodic Trends in Atomic Radii 263 Periodic Trends in Ionic Radii 263 Electron Configurations of Ions 264

7.4 Ionization Energy and Electron Affinity 267

Variations in Successive Ionization Energies 268
Periodic Trends in First Ionization Energies 269
Electron Affinity 270 Periodic Trends in Electron Affinity 271

7.5 Metals, Nonmetals, and Metalloids 272

Metals 273 Nonmetals 275 Metalloids 276

7.6 Trends for Group 1A and Group 2A Metals 276

Group 1A: The Alkali Metals 276

Group 2A: The Alkaline Earth Metals 280

7.7 Trends for Selected Nonmetals 281

Hydrogen 281 Group 6A: The Chalcogens 282
Group 7A: The Halogens 283
Group 8A: The Noble Gases 285

PREFACE

To the Instructor

Philosophy

We authors of *Chemistry: The Central Science* are delighted and honored that you have chosen us as your instructional partners for your general chemistry class. Collectively we have taught general chemistry to multiple generations of students. Therefore, we understand the challenges and opportunities of teaching a class that so many students take. We have also been active researchers who appreciate both the learning and the discovery aspects of the chemical sciences. Our varied, wide-ranging experiences have formed the basis of the close collaborations we have enjoyed as coauthors. In writing our book, our focus is on the students: We try to ensure that the text is not only accurate and up-to-date but also clear and readable. We strive to convey the breadth of chemistry and the excitement that scientists experience in making new discoveries that contribute to our understanding of the physical world. We want the student to appreciate that chemistry is not a body of specialized knowledge that is separate from most aspects of modern life, but central to any attempt to address a host of societal concerns, including renewable energy, environmental sustainability, and improved human health. Most of all, we want to provide you and your students the most effective tools for teaching and learning.

Publishing the fifteenth edition of this text bespeaks an exceptionally long record of successful textbook writing. We are appreciative of the loyalty and support the book has received over the years, and we are mindful of our obligation to justify each new edition. We begin our approach to each new edition with an intensive author retreat in which we ask ourselves the deep questions that we must answer before we can move forward. What justifies yet another edition? What is changing in the world not only of chemistry, but with respect to science education and the qualities of the students we serve? How can we help your students not only learn the principles of chemistry, but also become critical thinkers who can think more like chemists?

Answers to these questions lie only partly in the changing face of chemistry itself. The introduction of many new technologies has changed the landscape in the teaching of sciences at all levels. The use of online resources in accessing information and presenting learning materials has markedly changed the role of the textbook as one element among many tools for student learning. Our challenge as authors is to maintain the text as the primary source of chemical knowledge and practice, while at the same time integrating it with the new avenues for learning made possible by technology. This book incorporates a number of technologies to improve pedagogy, including use of computer-based classroom tools, such as Mastering Chemistry, which is continually evolving to provide more effective means of testing and evaluating student performance, while giving the student immediate and helpful feedback. Video feedback for a select number of *Exam Prep* questions is also available in Mastering Chemistry, which is new to this edition

As authors, we want this text to be a central, indispensable learning tool for students. Whether as a physical book or in electronic form, it can be carried everywhere and used at any time. It is the best place students can go to obtain the information outside of the classroom needed for learning, skill development, reference, and test preparation. The text, more effectively than any other instrument, provides the depth of coverage and coherent background in modern chemistry that students need to serve their professional interests and, as appropriate, to prepare for more advanced chemistry courses.

If the text is to be effective in supporting your role as instructor, it must be addressed to the students. We strive to keep our writing clear and interesting, complemented by figures and illustrations wherever possible. The book has numerous in-text study aids for students, including student-friendly learning objectives and follow-up self-assessment exercises for each section of the book, carefully placed descriptions of problem-solving strategies, and a wealth of problems in varying formats at the end of each chapter. We hope our cumulative experience as teachers is evident in our pacing, choice of examples, and the types of study aids and motivational tools we have employed. We believe students are more enthusiastic about learning chemistry when they see its importance relative to their own goals and interests; therefore, we have highlighted many important applications of chemistry in everyday life. We hope you are able to make use of this material.

It is our philosophy, as authors, that the text and all the supplementary materials provided to support its use must work in concert with you, the instructor. A textbook is only as useful to students as the instructor permits it to be. This book is replete with features that help students learn and that can guide them as they acquire both conceptual understanding and problem-solving skills. There is a great deal here for the students to use, too much for all of it to be absorbed by any student in a one-year course. You will be the guide to the best use of the book. Only with your active help will the students be able to utilize most effectively all that the text and its supplements offer. Students care about grades, of course, and with encouragement they will also become interested in the subject matter and care about learning. Please consider emphasizing features of the book that can enhance student appreciation of chemistry, such as the *Chemistry and Sustainability* and *Chemistry and Life* boxes that show how chemistry impacts modern life and its relationship to health and life processes. Also consider emphasizing conceptual understanding (placing less emphasis on simple manipulative, algorithmic problem solving) and urging students to use the rich on-line resources available.

Organization and Contents

The first five chapters give a largely macroscopic, phenomenological view of chemistry. The basic concepts introduced—such as nomenclature, stoichiometry, and thermochemistry—provide necessary background for many of the laboratory experiments performed in general chemistry. We believe an early introduction to thermochemistry is desirable because so much of our understanding of chemical processes is based on considerations of energy changes. By incorporating bond enthalpies in the Thermochemistry chapter we aim to emphasize the connection between the macroscopic properties of substances and the submicroscopic world of atoms and bonds. We believe we have produced an effective, balanced approach to teaching thermodynamics in general chemistry, as well as providing students with an introduction to some of the global issues involving energy production and consumption. It is no easy matter to walk the narrow pathway between trying to teach too much at too high a level versus resorting to oversimplifications. For the book as a whole, the emphasis has been on imparting *conceptual* understanding, as opposed to presenting equations into which students are supposed to plug numbers.

The next four chapters (Chapters 6–9) deal with electronic structure and bonding. For more advanced students, *A Closer Look* boxes in Chapters 6 and 9 highlight radial probability functions and the phases of orbitals. Placing this latter discussion in *A Closer Look* box in Chapter 9 enables those who wish to cover this topic to do so, while others may decide to bypass it. For those instructors who wish to take an "atoms first" approach to teaching chemistry, starting with Chapters 1, 2, and 6 (while filling in concepts and problem-solving skills from Chapters 3–5 as they come up, especially in the laboratory) may work well.

In Chapters 10–13, the focus of the text changes to the next level of the organization of matter: examining the states of matter. Chapters 10 and 11 deal with gases, liquids, and intermolecular forces, while Chapter 12 is devoted to solids, presenting a contemporary view of the solid state as well as of modern materials accessible to general chemistry students. Chapter 12 provides an opportunity to show how abstract chemical bonding concepts impact real-world applications. The modular organization of the chapter allows you to tailor your coverage to focus on the materials (semiconductors, polymers, nanomaterials, and so forth) that are most relevant to your students and your own interests. This section of the book concludes with Chapter 13, which covers the formation and properties of solutions.

The next several chapters examine the factors that determine the speed and extent of chemical reactions: kinetics (Chapter 14), equilibria (Chapters 15–17), thermodynamics (Chapter 19), and electrochemistry (Chapter 20). Also in this section is a chapter on environmental chemistry (Chapter 18), in which the concepts developed in preceding chapters are applied to a discussion of the atmosphere and hydrosphere. This chapter has increasingly become focused on green chemistry and the impacts of human activities on Earth's water and atmosphere, and expands on many of the concepts first introduced in the *Chemistry and Sustainability* boxes.

After a discussion of nuclear chemistry (Chapter 21), the book ends with three survey chapters. Chapter 22 deals with nonmetals, Chapter 23 with the chemistry of transition metals, including coordination compounds, and Chapter 24 with the chemistry of organic compounds and elementary biochemical themes. These final four chapters are developed in an independent, modular fashion and can be covered in any order.

Our chapter sequence provides a fairly standard organization, however we recognize that not everyone teaches all the topics in the order we have chosen. We have, therefore, made sure instructors can make common changes in teaching sequence with no loss in student comprehension. In particular, many instructors prefer to introduce gases (Chapter 10) after stoichiometry (Chapter 3) rather than with states of matter. The chapter on gases has been written to permit this change with *no* disruption in the flow of material. It is also possible to treat balancing redox equations (Sections 20.1 and 20.2) earlier, after the introduction of redox reactions in Section 4.4. Finally, some instructors like to cover organic chemistry (Chapter 24) right after bonding (Chapters 8 and 9). This, too, is a largely seamless move.

We have brought students into greater contact with descriptive organic and inorganic chemistry by integrating examples throughout the text. You will find pertinent and relevant examples of "real" chemistry woven into all the chapters to illustrate principles and applications. Some chapters, of course, more directly address the "descriptive" properties of elements and their compounds, especially Chapters 4, 7, 11, 18, and 22–24. We also incorporate descriptive organic and inorganic chemistry in the end-of-chapter exercises.

Major Global Changes in This Edition

As with every new edition of *Chemistry: The Central Science,* the book has undergone a great many changes as we strive to keep the content current, and to improve the clarity and effectiveness of the text, the art, and the exercises. Among the myriad changes there are certain points of emphasis that we use to organize and guide the revision process. In creating the fifteenth edition, our revision was organized around the following points:

- We continue to use our in-classroom experiences with today's students to develop new tools that make the learning of chemistry more effective for students. In particular, we continue to develop new ways in which we can make our text a better, more indispensable learning tool for students. First, we have added *Learning Objectives* to each section of the text. These targeted goals are written in a student-friendly, easily understood manner which emphasizes the important concepts that provide students with achievable goals in their studies. Up to six learning objectives are placed in a margin box at the beginning of each section for ease of use. Then, at the end of each section, we have added a set of *Self-Assessment Exercises* for the students to complete as the equivalent of a low-stakes quiz as they proceed through the text. The author team was careful to ensure that each learning objective is covered by a self-assessment exercise. The self-assessment exercises, assignable in

Mastering, are structured as multiple-choice questions with wrong answers (distractors) chosen to probe common misconceptions and errors that students tend to make. Responses, both correct and incorrect, contain feedback written by the author team to help students recognize their mistakes and provides hints to get on the right track if they select the wrong answer. This organizational structural change has meant that some sections were combined with others, compared to previous editions of the book.

- At the end of each chapter are a series of *Exam Prep* questions. These multiple-choice questions, assignable in Mastering, are tied to each chapter's *Learning Objectives* and constitute what amounts to a practice exam for students to take on their own. As with the self-assessment exercises each answer contains clear, concise feedback written by the authors.
- Extensive effort has gone into creating enhanced content for the eText version of this book to make it so much more than just an electronic copy of the physical textbook. A select number of the Exam Prep questions include worked out solution videos, which allow students to check their work and solidify their understanding as they prepare for their midterm exams. These questions can also be assigned in Mastering Chemistry.
- Chemistry as the central science is intimately tied to larger issues such as climate change, humanity's use of energy, abundance of clean water, food insecurity, and more. Therefore, many of the former *Chemistry Put to Work* boxes have been reimagined and rewritten as *Chemistry and Sustainability* boxes, to showcase the means by which chemists contribute to the understanding of, and movement toward, a sustainable society. We maintain our focus on the positive aspects of chemistry without neglecting problems that can arise in an increasingly technological world. Our goal is to help students appreciate the real-world perspective of chemistry and the ways in which chemistry affects their lives. To address some of the most pressing societal issues of our time many new boxes have been added, including an introduction to these boxes in Chapter 1, which highlights the *UN Sustainability Development Goals*.
- The *Additional Exercises* at the end of each chapter are no longer separated into "additional exercises," and "integrative exercises," nor are brackets used to indicate problems that are abnormally difficult. For the student, this simulates the more real-world environment of an examination where such distinctions are not made.
- Throughout the text, updates to the periodic table and numerical constants have been implemented; for instance, in 2019, the values of Avogadro's number and a number of other physical constants were redefined, and we have included the most current values.
- Astute readers may notice the *Give It Some Thought* feature has been removed. The removal of this feature makes the reading experience less fragmented. The best *Give It Some Thought* questions have been reimagined as multiple-choice questions that are now part of the Self-Assessment Exercises and Exam Prep questions.

Chapter-Level Changes in This Edition

Chapter 1 continues the trend from the fourteenth edition to emphasize, early on, the importance of energy. The inclusion of energy in the opening chapter provides much greater flexibility for the order in which subsequent chapters can be covered. The *Chemistry and Sustainability* boxes are introduced in this chapter to frame the understanding that, historically, chemistry has had both positive and negative impacts on sustainability. More depth has been added to the discussion of significant figures compared to previous editions.

In Chapter 2, the treatment of organic chemistry nomenclature has been expanded to better match the long-standing section on inorganic nomenclature. This change involved moving some material, including end-of-chapter exercises, from Chapter 24. Inorganic acids such as HCl and organic acids such as acetic acid are now clearly distinguished.

In Chapter 5, the discussion of energy has been updated and expanded, especially regarding the section on foods and fuels, to connect directly to the focus on sustainability in the text.

In Chapter 6, a new (nearly) full-page figure has been added that shows the relationship between the wave function, the probability density, and the radial probability function for the 1*s*, 2*s* and 3*s* orbitals. By explicitly showing the wave functions, instructors who want to cover phases of orbitals have a better fundamental grounding with which to do so.

In Chapter 10, the average speed of gas molecules is now quantitatively described, in addition to the root-mean-square speed and the most probable speed. The discussion of diffusion and mean free path has been expanded to introduce the students to the concept of the random walk.

In Chapter 13, the explanation of why the solubility of gaseous and solid solutes typically change in the opposite direction with temperature is significantly expanded. The effects of entropy are emphasized, to the extent they can be in this chapter where entropy is first introduced but not covered in full detail. In acknowledgment of the complex interplay of enthalpy and entropy, some details are left to Chapter 19. New material that explores the use of reverse osmosis to desalinate ocean water has been added (some of this material was previously in Chapter 18).

In Chapter 14, sections have been renamed to better reflect their content. A new *Closer Look* box on diffusion-controlled reactions and activation-controlled reactions, highly relevant to reaction mechanisms, has been added.

In Chapter 15, the discussion of the Haber process has been expanded to show both the positive and negative implications of the process with respect to sustainability: the importance of the Haber process in addressing food insecurity vis-à-vis the enormous energy consumption and carbon footprint of the process.

In Chapter 16, the discussion of Lewis acids and bases has been moved from the end of the chapter to the first section where the Arrhenius and Brønsted-Lowry definitions of acids and bases are introduced. This rearrangement makes for a more natural discussion of the acidic properties of small, highly charged cations in the section on the acid–base properties of salt solutions.

Chapter 17 has been renamed to make its content (buffer, titrations, solubility equilibria) more clear.

Many aspects of Chapter 18 (ozone hole, atmospheric CO_2 levels, acid rain, ocean acidification, etc.) are constantly changing. This material has been revised to reflect the most up-to-date data and scientific consensus on future trends.

In Chapter 19, we have substantially rewritten the early sections to help students better understand the concepts of spontaneous, nonspontaneous, reversible, and irreversible processes and their relationships. These improvements have led to a clearer definition of entropy. The topical box on "Entropy and Human Society" has been revised as a *Chemistry and Sustainability* feature, with a greater emphasis on the sustainability aspects of the second law of thermodynamics.

In Chapter 21, the discussion of the various means of generating electricity has been revised, and a section on the health hazards of environmental radon has been added.

Finally, in Chapter 24 a new Chemistry and Life box on COVID-19 and mRNA vaccines has been added.

To the Student

Chemistry: The Central Science, Fifteenth Edition, has been written to introduce you to modern chemistry. As authors, we have, in effect, been engaged by your instructor to help you learn chemistry. Based on the comments of students and instructors who have used this book in its previous editions, we believe that we have done that job well. Of course, we expect the text to continue to evolve through future editions. We invite you to write to tell us what you like about the book so we will know where we have helped you most. We would also like to learn of any shortcomings in an effort improve the book in subsequent editions. Our addresses are given at the end of the Preface.

Advice for Learning and Studying Chemistry

Learning chemistry requires both the assimilation of many concepts and the development of analytical skills. In this text, we have provided you with numerous tools to help you succeed in both tasks. If you are going to succeed in your chemistry course, you will have to develop good study habits. Science courses, and chemistry in particular, make different demands on your learning skills than do other types of courses. We offer the following tips for success in your study of chemistry:

Don't fall behind! As the course moves along, new topics will build on material already presented. If you don't keep up with your reading and problem solving, you will find it much harder to follow the lectures and discussions on current topics. Experienced teachers know that students who read the relevant sections of the text *before* coming to a class learn more from the class and retain greater recall. "Cramming" just before an exam has been shown to be an ineffective way to study any subject, chemistry included.

Focus your study. The amount of information you will be expected to learn may seem overwhelming. We have tried to help you by incorporating *Learning Objectives* into the beginning of each section within each chapter; with accompanying *Self-Assessment Exercises* at the end each section so you can test your knowledge. At the end of each chapter, we provide you with *Exam Prep* questions, which you can think of as a multiple-choice practice exam. During your time with your instructor in the classroom, it is essential to recognize those concepts and skills that are particularly important. Pay attention to what your instructor is emphasizing. As you work through the *Sample Exercises* and homework assignments, try to see what general principles and skills they employ. Use the *What's Ahead* feature at the beginning of each chapter to help orient yourself to what is important in each chapter. A single reading of a chapter will generally not be enough for successful learning of chapter concepts and problem-solving skills. You will often need to go over assigned materials more than once. Don't skip the *Go Figure* features, *Sample Exercises,* and *Practice Exercises.* These are your guides to whether you are learning the material. They are also good preparation for test-taking. The *Key Equations* at the end of the chapter will also help you focus your study.

Keep good lecture notes. Your lecture notes will provide you with a clear and concise record of what your instructor regards as the most important material to learn. Using your lecture notes in conjunction with this text is the best way to determine which material to study.

Skim topics in the text before they are covered in lecture. Reviewing a topic before lecture will make it easier for you to take good notes. First read the *What's Ahead* points and the end-of-chapter *Summary;* then quickly read through the chapter, skipping Sample Exercises and supplemental sections. Paying attention to the titles of sections and subsections gives you a feeling for the scope of topics. Try to avoid thinking that you must learn and understand everything right away.

Do a certain amount of preparation before lecture. More than ever, instructors are using the lecture period not simply as a one-way channel of communication from teacher to student. Rather, they expect students to come to class ready to work on problem solving and critical thinking. Coming to class unprepared is not a good idea for any lecture environment, but it certainly is not an option for an active learning classroom if you aim to do well in the course.

After lecture, carefully read the topics covered in class. As you read, pay attention to the concepts presented and to the application of these concepts in the *Sample Exercises.* Once you think you understand a *Sample Exercise,* test your understanding by working the accompanying *Practice Exercise.*

Learn the language of chemistry. As you study chemistry, you will encounter many new words. It is important to pay attention to these words and to know their meanings or the entities to which they refer. Knowing how to identify chemical substances from their names is an important skill; it can help you avoid painful mistakes on examinations. For example, "chlorine" and "chloride" refer to very different things.

Attempt the assigned end-of-chapter exercises. Working the exercises selected by your instructor provides necessary practice in recalling and using the essential ideas of the chapter. You cannot learn merely by observing; you must be a participant. In particular, try to resist checking the *Solutions Manual* (if you have one) until you have made a sincere effort to solve the exercise yourself. If you get stuck on an exercise, however, get help from your instructor, your teaching assistant, or another student. Spending more than 20 minutes on a single exercise is rarely effective unless you know that it is particularly challenging.

Learn to think like a scientist. This book is written by scientists who love chemistry. We encourage you to develop your critical thinking skills by taking advantage of features in this new edition, such as exercises that focus on conceptual learning and the *Design an Experiment* exercises.

Use online resources. Some things are more easily learned by discovery, and others are best shown in three dimensions. If your instructor has included Mastering Chemistry with your book, take advantage of the unique tools it provides to get the most out of your time in chemistry.

The bottom line is to work hard, study effectively, and use the tools available to you, including this textbook. We want to help you learn more about the world of chemistry and why chemistry is the central science. If you really learn chemistry, you can be the life of the party, impress your friends and parents, and . . . well, also pass the course with a good grade.

Answers to Go Figures, Practice Exercises and Self Assessment Exercises are available as PDF files within Mastering Chemistry. We invite instructors to share these resources as needed.

Acknowledgments

The production of a textbook is a team effort requiring the involvement of many people besides the authors who contributed hard work and talent to bring this edition to life. Although their names don't appear on the cover of the book, their creativity, time, and support have been instrumental in all stages of its development and production.

Each of us has benefited greatly from discussions with colleagues and from correspondence with instructors and students both here and abroad. Colleagues have also helped immensely by reviewing our materials, sharing their insights, and providing suggestions for improvements. For this edition, we were particularly blessed with an exceptional group of accuracy checkers who read through our materials looking for both technical inaccuracies and typographical errors.

We would also like to express our gratitude to our partners at Pearson whose hard work, imagination, and commitment have contributed so greatly to the final form of this edition: Deb Harden and Ian Desrosiers, our Content Analyst and Product Manager, respectively, for their unflagging enthusiasm, continuous encouragement, and support; John Murdzek, our Development Editor, whose depth of experience, deep knowledge of chemistry, and careful attention to detail were invaluable to this revision; Matt Walker, Content Development Manager, who has brought his experience and insight to oversight of the entire project; and Beth Sweeten, Senior Content Producer, for keeping us on task and helping us to prioritize the many tasks that go into a revision of this scope. This revision would not have been possible without their hard work and guidance.

There are many others who also deserve special recognition, including the following: Mary Tindle, our production editor, whose expertise, advice, flexibility, and commitment to accuracy have allowed us to produce a textbook that is both beautiful and of high quality; and Roxy Wilson (University of Illinois), who so ably coordinated the difficult job of working out solutions to the end-of-chapter exercises. Finally, we wish to thank our families and friends for their love, support, encouragement, and patience as we brought this fifteenth edition to completion.

ABOUT THE AUTHORS

The Brown/Lemay/Bursten/Murphy/Woodward/Stoltzfus Author Team values collaboration as an integral component to overall success. While each author brings unique talent, research interests, and teaching experiences, the team works together to review and develop the entire text. It is this collaboration that keeps the content ahead of educational trends and contributes to continuous innovations in teaching and learning throughout the text and technology. Some of the new key features in the fifteenth edition and accompanying Mastering Chemistry course are highlighted on the upcoming pages.

Theodore L. Brown received his Ph.D. from Michigan State University in 1956. Since then, he has been a member of the faculty of the University of Illinois, Urbana-Champaign, where he is now Professor of Chemistry, Emeritus. He served as Vice Chancellor for Research, and Dean of The Graduate College, from 1980 to 1986, and as Founding Director of the Arnold and Mabel Beckman Institute for Advanced Science and Technology from 1987 to 1993. Professor Brown has been an Alfred P. Sloan Foundation Research Fellow and has been awarded a Guggenheim Fellowship. In 1972 he was awarded the American Chemical Society Award for Research in Inorganic Chemistry and received the American Chemical Society Award for Distinguished Service in the Advancement of Inorganic Chemistry in 1993. He has been elected a Fellow of the American Association for the Advancement of Science, the American Academy of Arts and Sciences, and the American Chemical Society.

H. Eugene Lemay, Jr., received his B.S. degree in Chemistry from Pacific Lutheran University (Washington) and his Ph.D. in Chemistry in 1966 from the University of Illinois, Urbana-Champaign. He then joined the faculty of the University of Nevada, Reno, where he is currently Professor of Chemistry, Emeritus. He has enjoyed Visiting Professorships at the University of North Carolina at Chapel Hill, at the University College of Wales in Great Britain, and at the University of California, Los Angeles. Professor LeMay is a popular and effective teacher, who has taught thousands of students during more than 40 years of university teaching. Known for the clarity of his lectures and his sense of humor, he has received several teaching awards, including the University Distinguished Teacher of the Year Award (1991) and the first Regents' Teaching Award given by the State of Nevada Board of Regents (1997).

Bruce E. Bursten received his Ph.D. in Chemistry from the University of Wisconsin in 1978. After two years as a National Science Foundation Postdoctoral Fellow at Texas A&M University, he joined the faculty of The Ohio State University, where he rose to the rank of Distinguished University Professor. In 2005, he moved to the University of Tennessee, Knoxville, as Distinguished Professor of Chemistry and Dean of the College of Arts and Sciences. In 2015, he moved to Worcester Polytechnic Institute as Provost and Professor of Chemistry and Biochemistry. Professor Bursten has been a Camille and Henry Dreyfus Foundation Teacher-Scholar and an Alfred P. Sloan Foundation Research Fellow, and he is a Fellow of both the American Association for the Advancement of Science and the American Chemical Society. At Ohio State he received the University Distinguished Teaching Award in 1982 and 1996, the Arts and Sciences Student Council Outstanding Teaching Award in 1984, and the University Distinguished Scholar Award in 1990. He received the Spiers Memorial Prize and Medal of the Royal Society of Chemistry in 2003, the Morley Medal of the Cleveland Section of the American Chemical Society in 2005, and the American Chemical Society Award for Distinguished Service in the Advancement of Inorganic Chemistry in 2020. He was President of the American Chemical Society for 2008 and Chair of the Section on Chemistry of the American Association for the Advancement of Science in 2015. Professor Bursten's research program focuses on theoretical studies of compounds of the transition-metal and actinide elements.

Catherine J. Murphy received two B.S. degrees, one in Chemistry and one in Biochemistry, from the University of Illinois, Urbana-Champaign, in 1986. She received her Ph.D. in Chemistry from the University of Wisconsin in 1990. She was a National Science Foundation and National Institutes of Health Postdoctoral Fellow at the California Institute of Technology from 1990 to 1993. In 1993, she joined the faculty of the University of South Carolina, Columbia, becoming the Guy F. Lipscomb Professor of Chemistry in 2003. In 2009 she moved to the University of Illinois, Urbana-Champaign, as the Peter C. and Gretchen Miller Markunas Professor of Chemistry. Professor Murphy has been honored for both research and teaching as a Camille Dreyfus Teacher-Scholar, an Alfred P. Sloan Foundation Research Fellow, a Cottrell Scholar of the Research Corporation, a National Science Foundation CAREER Award winner, and a subsequent NSF Award for Special Creativity. She has also received a USC Mortar Board Excellence in Teaching Award, the USC Golden Key Faculty Award for Creative Integration of Research and Undergraduate Teaching, the USC Michael J. Mungo Undergraduate Teaching Award, and the USC Outstanding Undergraduate Research Mentor Award. From 2006–2011, Professor Murphy served as a Senior Editor for the *Journal of Physical Chemistry*; in 2011, she became the Deputy Editor for the *Journal of Physical Chemistry C*. She is an elected Fellow of the American Association for the Advancement of Science (2008), the American Chemical Society (2011), the Royal Society of Chemistry (2014), and the U.S. National Academy of Sciences (2015). Professor Murphy's research program focuses on the synthesis, optical properties, surface chemistry, biological applications, and environmental implications of colloidal inorganic nanomaterials.

Patrick M. Woodward received B.S. degrees in both Chemistry and Engineering from Idaho State University in 1991. He received a M.S. degree in Materials Science and a Ph.D. in Chemistry from Oregon State University in 1996. He spent two years as a postdoctoral researcher in the Department of Physics at Brookhaven National Laboratory. In 1998, he joined the faculty of the Chemistry Department at The Ohio State University where he currently holds the rank of Professor. He has been a visiting professor at Durham University in the UK, the University of Sydney in Australia, and the University of Bordeaux in France. Professor Woodward is a Fellow of the American Chemical Society and has been recognized with an Alfred P. Sloan Foundation Research Fellowship and a National Science Foundation CAREER Award. He has served as Vice Chair for Undergraduate Studies in the Department of Chemistry and Biochemistry at Ohio State University, and director of the Ohio REEL program. Professor Woodward's research program focuses on understanding the links between bonding, structure, and properties of solid-state inorganic materials.

Matthew W. Stoltzfus received his B.S. degree in Chemistry from Millersville University in 2002 and his Ph.D. in Chemistry in 2007 from The Ohio State University. He spent two years as a teaching postdoctoral assistant for the Ohio REEL program, an NSF-funded center that works to bring authentic research experiments into the general chemistry lab curriculum in 15 colleges and universities across the state of Ohio. In 2009, he joined the faculty of Ohio State where he currently holds the position of Senior Lecturer. In addition to lecturing on general chemistry, he served as a Faculty Fellow for the Digital First Initiative, inspiring instructors to offer engaging digital learning content to students through emerging technology. Through this initiative, he developed an iTunes U general chemistry course, which has attracted over 220,000 students from all over the world. The iTunes U course, along with the videos at www.drfus.com, are designed to supplement the text and can be used by any general chemistry student. Stoltzfus has received several teaching awards, including the inaugural Ohio State University 2013 Provost's Award for Distinguished Teaching by a Lecturer, and he is recognized as an Apple Distinguished Educator.

INTRODUCTION: MATTER, ENERGY, AND MEASUREMENT

▲ THE MANUFACTURE OF SYNTHETIC PIGMENTS is one of the oldest examples of industrial chemistry. The impressionist artists made extensive use of the bold colors of the newly available pigments, as exemplified in van Gogh's painting *Road with Cyprus and Star*.

WHAT'S AHEAD

1.1 ▶ The Study of Chemistry Learn what chemistry is, what atoms and molecules are, and why it is useful to study chemistry.

1.2 ▶ Classifications of Matter Examine fundamental ways to classify matter; distinguish between *pure substances* and *mixtures*, and between *elements* and *compounds*.

1.3 ▶ Properties of Matter Use *properties* to characterize, identify, and separate substances; distinguish between chemical and physical properties.

1.4 ▶ The Nature of Energy Explore the nature of energy and the forms it takes, notably kinetic energy and potential energy.

1.5 ▶ Units of Measurement Learn how numbers and units of the metric system are used in science to describe properties.

1.6 ▶ Uncertainty in Measurement and Significant Figures Use significant figures to express the inherent uncertainty in measured quantities and in calculations.

1.7 ▶ Dimensional Analysis Learn to carry numbers and units through calculations; use units to check if a calculation is correct.

The title of this book is *Chemistry: The Central Science* because much of what goes on in the world around us involves chemistry. **Chemistry** is the study of matter, its properties, and the changes that matter undergoes. As you progress in your study, you will come to see how chemical principles operate in all aspects of our daily lives, including the ways our bodies process the food that we eat, the production of energy to power our vehicles and portable electronic devices, the brilliant color changes in fall leaves, and critical issues in our environment. We will also see that the properties of substances can be tailored for specific applications by controlling their composition and structure.

This first chapter provides an overview of what chemistry is about and what chemists do. The "What's Ahead" list in this and all of the chapters gives an overview of the chapter organization and of some of the ideas we will consider.

1.1 | The Study of Chemistry

Learning Objectives

When you finish Section 1.1, you should be able to:

- Explain the concepts of matter, atoms, and molecules.
- Demonstrate how molecules and the atoms that compose them are represented by molecular models.

Chemistry is at the heart of many changes we see in the world around us, and it accounts for the different properties we see in matter. To understand how these changes and properties arise, we need to look far beneath the surfaces of our everyday observations.

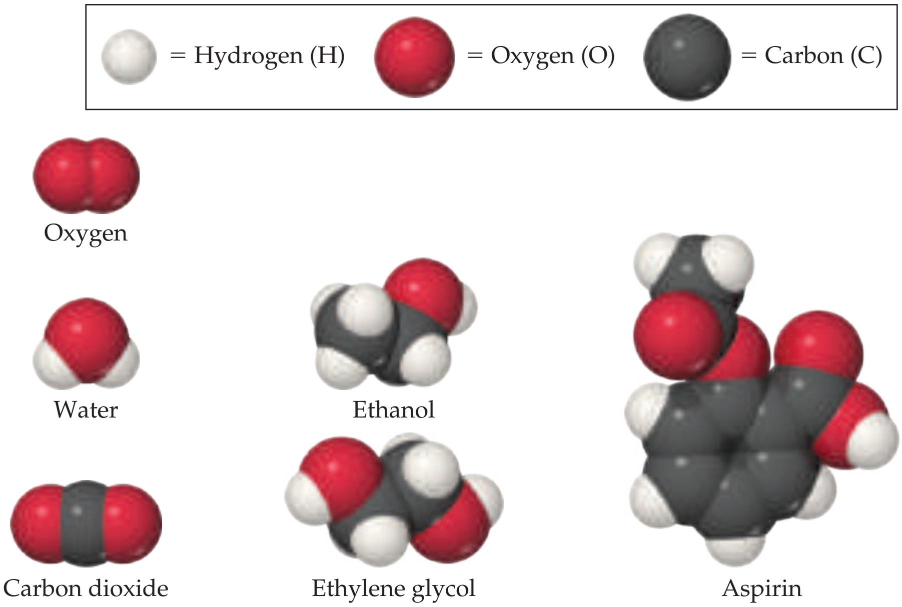
The Atomic and Molecular Perspective of Chemistry

Chemistry is the study of the properties and behavior of matter. **Matter** is the physical material of the universe; it is anything that has mass and occupies space. A **property** is any characteristic that allows us to recognize a particular type of matter and to distinguish it from other types. This book, your body, the air you are breathing, and the clothes you are wearing are all samples of matter. We observe a tremendous variety of matter in our world, but countless experiments have shown that all matter is composed of combinations of a little over 100 substances called **elements**. One of our major goals will be to relate the properties of matter to its composition—that is, to the specific elements it contains.

Chemistry also provides a background for understanding the properties of matter in terms of **atoms**, the exceedingly small building blocks of matter. Each element is composed of a unique kind of atom. We will see that the properties of matter relate to both the kinds of atoms the matter contains (*composition*) and the arrangements of these atoms (*structure*).

In a **molecule**, two or more atoms are joined in specific shapes. Throughout this text we represent molecules using colored spheres to show how the atoms are connected (Figure 1.1). The color provides a convenient way to distinguish between atoms of different elements. For example, notice that the molecules of ethanol and ethylene

Go Figure Which molecule has the most carbon atoms? How many carbon atoms does it contain?



▲ **Figure 1.1 Molecular models.** The white, black, and red spheres represent atoms of hydrogen, carbon, and oxygen, respectively.

glycol in Figure 1.1 have different compositions and structures. Ethanol contains one oxygen atom, depicted by one red sphere, whereas ethylene glycol contains two oxygen atoms.

Even apparently minor differences in the composition or structure of molecules can cause profound differences in properties. For example, ethanol and ethylene glycol (Figure 1.1) appear to be quite similar. Ethanol is the alcohol in beverages such as beer and wine, whereas ethylene glycol is a viscous liquid used as automobile antifreeze. The properties of these two substances differ in many ways, as do their biological activities. Ethanol is consumed throughout the world, but ethylene glycol is highly toxic. One of the challenges chemists undertake is to alter the composition or structure of molecules in a controlled way, creating new substances with different properties. For example, the common drug aspirin (Figure 1.1) was first synthesized in 1897 in a successful attempt to improve on a natural product extracted from willow bark that had long been used to alleviate pain.

Every change in the observable world—from boiling water to the changes that occur as our bodies combat invading viruses—has its basis in the world of atoms and molecules. Thus, as we proceed with our study of chemistry, we will find ourselves thinking in two realms: the *macroscopic* realm of ordinary-sized objects (*macro* means large) and the *submicroscopic* realm of atoms and molecules. We make our observations in the macroscopic world, but to understand that world, we must visualize how atoms and molecules behave at the submicroscopic level. Chemistry is the science that seeks to understand the properties and behavior of matter by studying the properties and behavior of atoms and molecules.

Why Study Chemistry?

Chemistry is all around us. Examples include the household chemicals used for cleaning and disinfecting that became so important during the COVID-19 pandemic (**Figure 1.2**). The chemical industry in the United States is nearly a $600 billion enterprise that employs over 500,000 people and accounts for nearly 10% of all U.S. exports.

Kills 99.9% of Viruses† & Bacteria
CLOROX
DISINFECTING WIPES
Kills Staph, E. coli, MRSA, Salmonella, Strep, Kleb
Kills Cold & Flu Viruses
Kills 99.999% of Bacteria in 10 Seconds
Great for Wood, Granite, Stainless Steel
Purell
ADVANCED HAND SANITIZER
KILLS COLD & FLU VIRUS
Professional Lysol
KILLS 99.9% OF VIRUSES & BACTERIA
Disinfectant Spray
Eliminates odor
Crisp Linen scent

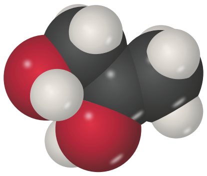
▲ **Figure 1.2** **Household chemicals.** The cleansing and disinfecting properties of these household products used so extensively during the COVID-19 pandemic are due to the chemicals they contain.

Chemistry lies near the heart of many matters of public concern, such as improvement of health care, conservation of natural resources, protection of the environment, and the supply of energy needed to keep society running. Using chemistry, we have discovered and continually improved upon pharmaceuticals, fertilizers and pesticides, plastics, solar panels, light-emitting diodes (LEDs), and building materials. We have also discovered that some chemicals are harmful to our health or the environment. This means that we must be sure that the materials with which we come into contact are safe. As a citizen and consumer, it is in your best interest to understand the effects, both positive and negative, that chemicals can have—we want you to have a balanced outlook regarding their uses.

You may be studying chemistry because it is an essential part of your curriculum. Your major might be chemistry, or it could be biology, engineering, pharmacy, agriculture, geology, or some other field. Chemistry is central to a fundamental understanding of governing principles in many science-related fields. For example, our interactions with the material world raise basic questions about the materials around us. We will see that chemistry is central to most realms of modern life.

Self-Assessment Exercises

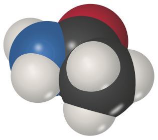
SAE 1.1 Which of the following statements is *false*? (**a**) All matter is composed of atoms of the elements. (**b**) The atoms of different elements must be different. (**c**) A molecule must contain atoms from two or more elements. (**d**) Different molecules can be made from the same elements. (**e**) Matter has mass and occupies space.



Propylene glycol

SAE 1.2 The molecule shown here is *propylene glycol*, a substance that is used extensively in the chemical industry. The color key is: White = hydrogen, red = oxygen, black = carbon. How many carbon atoms are in a molecule of propylene glycol? (**a**) 2 (**b**) 3 (**c**) 5 (**d**) 8 (**e**) 13

SAE 1.3 The molecule shown here is called *acetamide*. How many different elements and how many atoms are in a molecule of acetamide? (**a**) 3 elements, 4 atoms (**b**) 3 elements, 9 atoms (**c**) 4 elements, 4 atoms (**d**) 4 elements, 9 atoms (**e**) There is not enough information to answer the question.



Acetamide

1.2 Classifications of Matter

Learning Objectives

When you finish Section 1.2, you should be able to:

- Compare and contrast the different states of matter: solid, liquid, and gas.
- Distinguish among elements, compounds, and mixtures.
- Identify the atomic symbols of common elements.

As we progress through this text, we will continue to learn more about the properties of matter and how the atoms and elements that comprise matter affect those properties. Let's begin our study of chemistry by examining two fundamental ways in which matter is classified. Matter is typically characterized by its physical state (gas, liquid, or solid) and its composition (whether it is an element, a *compound*, or a *mixture*).

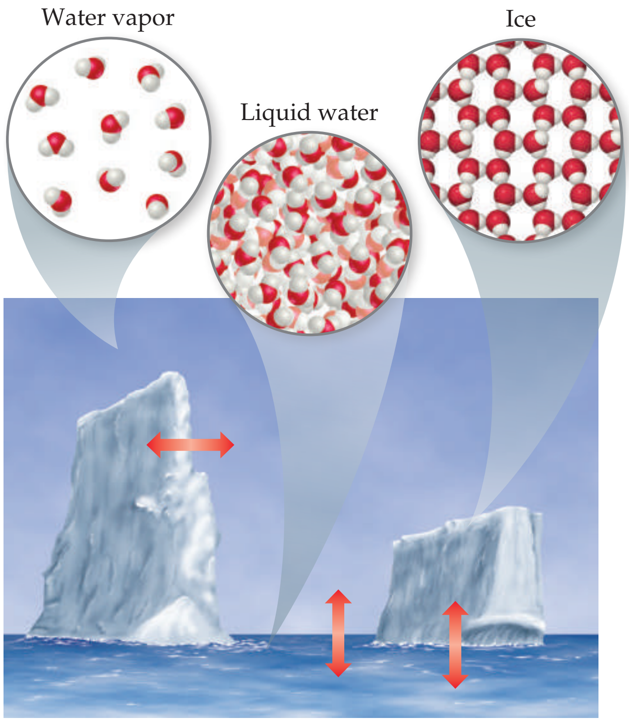
States of Matter

Think about what happens when liquid water freezes into ice. Both liquid water and ice consist of molecules of water, and yet we know there is a difference between them—one is liquid and one is solid. A sample of matter can be a gas, a liquid, or a solid. These three forms, called the **states of matter**, differ in some of their observable properties.

- A **gas** (also known as vapor) has no fixed volume or shape; rather, it uniformly fills its container. A gas can be compressed to occupy a smaller volume, or it can expand to occupy a larger one.
- A **liquid** has a distinct volume independent of its container, assumes the shape of the portion of the container it occupies, and is not easily compressed.
- A **solid** has both a definite shape and a definite volume and is not easily compressed.

The properties of the states of matter can be understood on the molecular level (**Figure 1.3**). In a gas, the molecules are far apart and moving at high speeds, colliding repeatedly with one another and with the walls of the container. Compressing a gas decreases the amount of space between molecules and increases the frequency of collisions between molecules but does not alter the size or shape of the molecules. In a liquid, the molecules are packed closely together but still move rapidly. The rapid movement allows the molecules to slide over one another; thus, a liquid pours easily. In a solid, the molecules are held tightly together, usually in definite arrangements in which the molecules can wiggle only slightly in their otherwise fixed positions. Thus, the distances between molecules are similar in the liquid and solid states, but while the molecules are for the most part locked in place in a solid, they retain considerable freedom of motion in a liquid. Changes in temperature and/or pressure can convert one state of matter to another, illustrated by such familiar processes as ice melting or water vapor condensing. We discuss these conversions from one state to another in greater detail in Chapter 11.

Go Figure In which form of water are the water molecules farthest apart?



▲ **Figure 1.3 The three physical states of water—water vapor, liquid water, and ice.** We can see the liquid and solid states but not the gas (vapor) state. The red arrows show that the three states of matter can interconvert.

Pure Substances

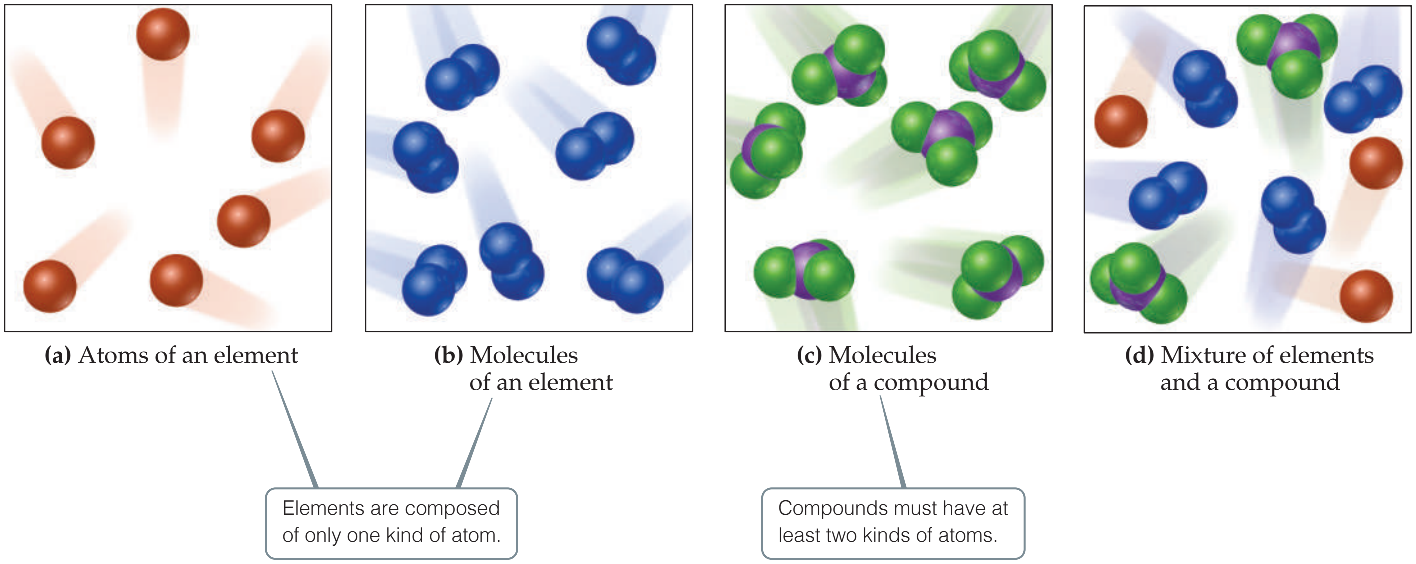
Most forms of matter we encounter—the air we breathe (a gas), the gasoline we burn in our cars (a liquid), and the sidewalk we walk on (a solid)—are not chemically pure. We can, however, separate these forms of matter into pure substances. A **pure substance** (usually referred to simply as a *substance*) is matter that has distinct properties and a composition that does not vary from sample to sample. Water and table salt (sodium chloride) are examples of pure substances.

All substances are either elements or compounds.

- *Elements* are substances that cannot be decomposed into simpler substances. On the molecular level, each element is composed of only one kind of atom [Figure 1.4(**a**) and (**b**)].
- **Compounds** are substances composed of two or more elements; they contain two or more kinds of atoms [Figure 1.4(**c**)]. Water, for example, is a compound composed of two elements: hydrogen and oxygen.

Figure 1.4(**d**) shows a mixture of substances. **Mixtures** are combinations of two or more substances in which each substance retains its chemical identity.

Go Figure How do the molecules of a compound differ from the molecules of an element?



(a) Atoms of an element

(b) Molecules of an element

(c) Molecules of a compound

(d) Mixture of elements and a compound

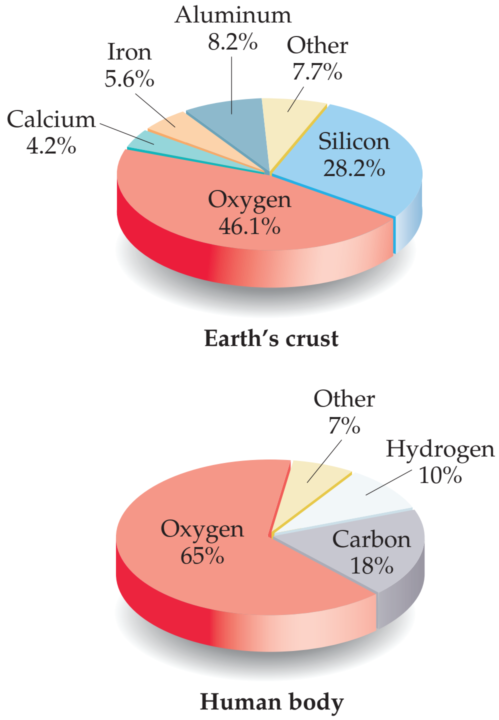
Elements are composed of only one kind of atom.

Compounds must have at least two kinds of atoms.

▲ **Figure 1.4 Molecular comparison of elements, compounds, and mixtures.**

Go Figure

If the lower pie chart were drawn as the percentage in terms of number of atoms rather than the percentage in terms of mass, would the hydrogen slice of the pie get larger or smaller?



▲ **Figure 1.5 Relative abundances of elements.*** Elements in percent by mass in Earth's crust and in the human body.

TABLE 1.1 Some Common Elements and Their Symbols

Carbon	C	Aluminum	Al	Copper	Cu (from cuprum)
Fluorine	F	Bromine	Br	Iron	Fe (from ferrum)
Hydrogen	H	Calcium	Ca	Lead	Pb (from plumbum)
Iodine	I	Chlorine	Cl	Mercury	Hg (from hydrargyrum)
Nitrogen	N	Helium	He	Potassium	K (from kalium)
Oxygen	O	Lithium	Li	Silver	Ag (from argentum)
Phosphorus	P	Magnesium	Mg	Sodium	Na (from natrium)
Sulfur	S	Silicon	Si	Tin	Sn (from stannum)

Elements

Currently, 118 elements are known, though they vary widely in abundance. Hydrogen constitutes about 74% of the mass in the Milky Way galaxy, and helium constitutes 24%. Closer to home, only five elements—oxygen, silicon, aluminum, iron, and calcium—account for over 90% of the mass of Earth's crust, and only three—oxygen, carbon, and hydrogen—account for over 90% of the mass of the human body (**Figure 1.5**).

Table 1.1 lists some common elements, along with the chemical *symbols* used to denote them. The symbol for each element consists of one or two letters, with the first letter capitalized. These symbols are derived mostly from the English names of the elements, but sometimes they are derived from a foreign name instead (see the last column in Table 1.1). You will need to know these symbols and learn others as we encounter them in the text.

All of the known elements and their symbols are listed on the front inside cover of this text in a table known as the *periodic table*. In the periodic table, the elements are arranged in columns so that closely related elements are grouped together. We describe the periodic table in more detail in Section 2.5 and consider the periodically repeating properties of the elements in Chapter 7.

Compounds

Most elements can interact with other elements to form compounds. For example, when hydrogen gas burns in oxygen gas, the elements hydrogen and oxygen combine to form the compound water. Because each molecule of water contains two hydrogen atoms and one oxygen atom, we denote the molecule as H_2O. The subscript 2 indicates that there are two H atoms in the molecule. When there is only one atom of an element in a molecule, as is the case for O in water, we do not explicitly use the subscript 1.

Water can be decomposed back into its elements by passing an electrical current through it (**Figure 1.6**).

Decomposing pure water into its constituent elements shows that it contains 11% hydrogen and 89% oxygen by mass, regardless of its source. This ratio is constant because every water molecule is composed of two hydrogen atoms and one oxygen atom:

Hydrogen atom (written H)

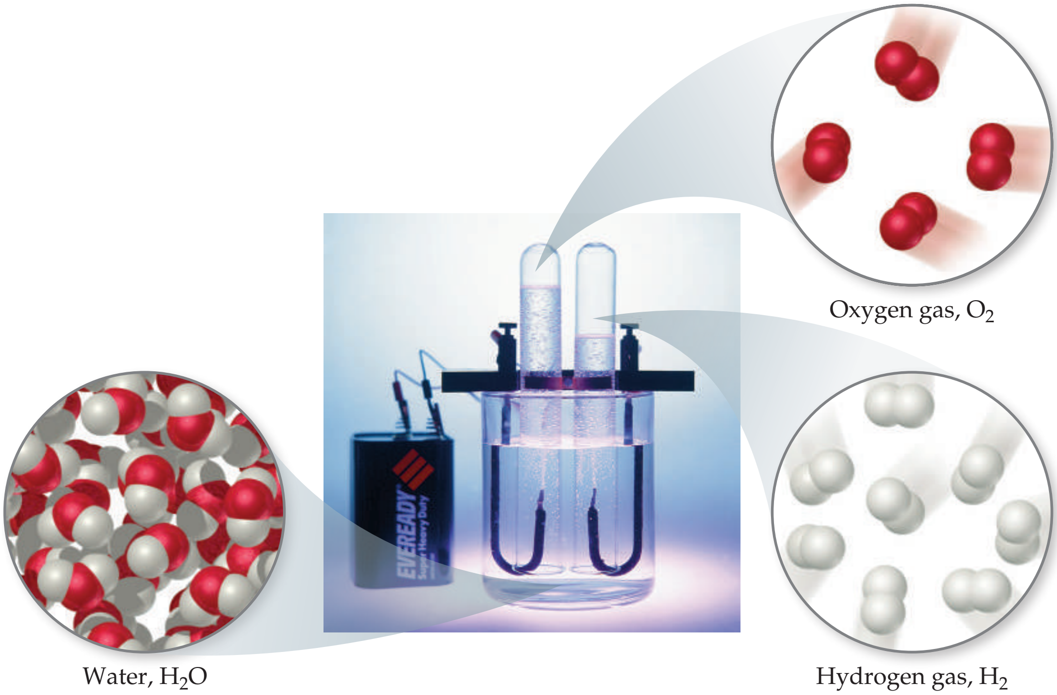
Oxygen atom (written O)

Water molecule (written H_2O)

The amount of oxygen by mass is greater than the amount of hydrogen by mass because oxygen atoms are heavier than hydrogen atoms.

***CRC Handbook of Chemistry and Physics*, 97th ed. (2016–2017), pp. 14–17.

Go Figure Is the volume of H_2 produced larger than the volume of O_2 produced because (**a**) hydrogen atoms are lighter than oxygen atoms, (**b**) hydrogen atoms are larger than oxygen atoms, or (**c**) each water molecule contains one oxygen atom and two hydrogen atoms?



▲ **Figure 1.6 Electrolysis of water.** Water decomposes into its component elements, hydrogen and oxygen, when an electrical current is passed through it. The volume of hydrogen, collected in the right test tube, is twice the volume of oxygen.

The elements hydrogen and oxygen themselves exist naturally as *diatomic* (two-atom) molecules:

Oxygen molecule (written O_2)

Hydrogen molecule (written H_2)

As seen in **Table 1.2**, the properties of water bear no resemblance to the properties of its component elements. Hydrogen, oxygen, and water are each a unique substance, a consequence of the uniqueness of their respective molecules.

TABLE 1.2 Comparison of Water, Hydrogen, and Oxygen

	Water	Hydrogen	Oxygen
State[a]	Liquid	Gas	Gas
Normal boiling point	100 °C	−253 °C	−183 °C
Density[a]	1000 g/L	0.084 g/L	1.33 g/L
Flammable	No	Yes	No

[a] At room temperature and atmospheric pressure.

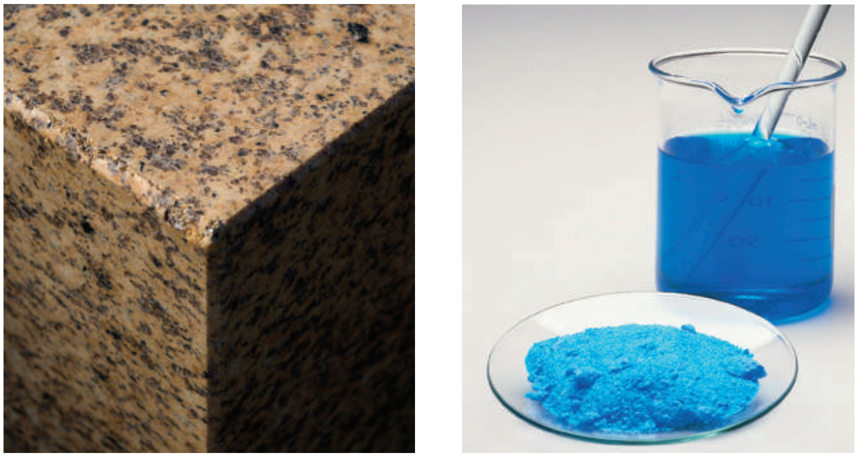
The observation that the elemental composition of a compound is always the same is known as the **law of constant composition** (or the **law of definite proportions**). French chemist Joseph Louis Proust (1754–1826) first stated the law in about 1800. Although this law has been known for 200 years, the belief persists among some people that a fundamental difference exists between compounds prepared in the laboratory and the corresponding compounds found in nature. This simply is not true. Regardless of its source—nature or a laboratory—a pure compound has the same composition and properties under the same conditions. Both chemists and nature must use the same elements and operate under the same natural laws. When two materials differ in composition or properties, either they are composed of different compounds or they differ in purity.

Mixtures

Most of the matter we encounter consists of mixtures of different substances. Each substance in a mixture retains its chemical identity and properties. In contrast to a pure substance, which by definition has a fixed composition, the composition of a mixture can vary. A cup of sweetened coffee, for example, can contain either a little sugar or a lot. The substances making up a mixture are called *components* of the mixture.

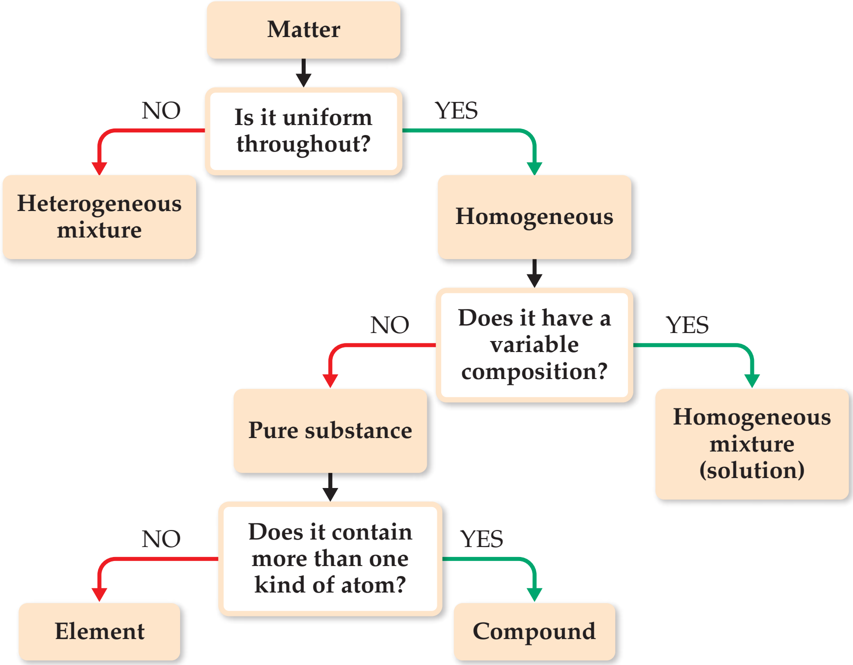
Some mixtures do not have the same composition, properties, and appearance throughout. Rocks and wood, for example, vary in texture and appearance in any typical sample. Such mixtures are *heterogeneous* [Figure 1.7(**a**)]. Mixtures that are uniform throughout are *homogeneous*. Air is a homogeneous mixture of nitrogen, oxygen, and smaller amounts of other gases. The nitrogen in air has all the properties of pure nitrogen because both the pure substance and the mixture contain the same nitrogen molecules. Salt, sugar, and many other substances dissolve in water to form homogeneous mixtures [Figure 1.7(**b**)]. Homogeneous mixtures are also called **solutions**. Although the term *solution* conjures up an image of a liquid, solutions can be solids, liquids, or gases.

In Figure 1.8 we summarize the classification of matter into elements, compounds, and mixtures. You should be comfortable in classifying substances among these three categories.



(a) (b)

▲ Figure 1.7 **Mixtures.** (a) Many common materials, including rocks, are heterogeneous mixtures. This photograph of granite shows a heterogeneous mixture of silicon dioxide and other metal oxides. (b) Homogeneous mixtures are called solutions. Many substances, including the blue solid shown here [copper(II) sulfate pentahydrate], dissolve in water to form solutions.



Matter
Is it uniform throughout?
NO
YES
Heterogeneous mixture
Homogeneous
Does it have a variable composition?
NO
YES
Pure substance
Homogeneous mixture (solution)
Does it contain more than one kind of atom?
NO
YES
Element
Compound

◀ **Figure 1.8 Classification of matter.** All pure matter is classified ultimately as either an element or a compound.

Sample Exercise 1.1

Distinguishing among Elements, Compounds, and Mixtures

Classify each of the following as an element, a compound, a homogeneous mixture, or a heterogeneous mixture: (**a**) molten iron; (**b**) a chocolate chip cookie; (**c**) a container of pure ethylene glycol (see Figure 1.1); (**d**) a cup of water with a teaspoon of sugar dissolved in it.

SOLUTION

We can follow the flowchart in Figure 1.8 to classify each substance: (**a**) Molten iron is simply iron heated to the point at which it melts into a liquid. It still contains only iron atoms and is therefore a pure substance that is an element. (**b**) A cookie contains several different substances in different amounts. It is not uniform throughout and is therefore a heterogeneous mixture. (**c**) As seen in Figure 1.1, an ethylene glycol molecule contains C, H, and O atoms. The sample of pure ethylene glycol is therefore a pure substance that is a compound. (**d**) The sugar water that results from dissolving sugar in water has the same composition throughout. It is a homogeneous mixture, also known as a solution.

▶ Practice Exercise

"White gold" contains gold and a "white" metal, such as palladium. Two samples of white gold differ in the relative amounts of gold and palladium they contain. Both samples are uniform in composition throughout. Use Figure 1.8 to classify white gold.

Self-Assessment Exercises

SAE 1.4 Which of the following processes is best described as a liquid turning into a gas? (**a**) snow melting (**b**) molten metal hardening upon cooling (**c**) rubbing alcohol evaporating from your skin (**d**) steam condensing on a cold surface (**e**) dry ice, which is frozen CO_2, evaporating

SAE 1.5 Which of the following characterizations is *incorrect*? (**a**) Chicken noodle soup is a heterogeneous mixture. (**b**) Aspirin is composed of 60.0% carbon, 4.5% hydrogen, and 35.5% oxygen by mass, regardless of its source. Aspirin is a compound. (**c**) The tanks that scuba divers use contain nitrogen and oxygen gas. The tanks contain a homogeneous mixture. (**d**) Yellow sulfur consists of molecules that contain eight-membered rings of sulfur atoms. Yellow sulfur is a compound. (**e**) The graphite in lead pencils consists entirely of sheets of carbon atoms. Graphite is a form of an element.

SAE 1.6 The compound called *heme* is present in red blood cells. Heme contains carbon, hydrogen, iron, nitrogen, and oxygen. Which of the following is the correct list of the symbols of the elements in a heme molecule? (**a**) Ca, Hy, Ir, Ni, Ox (**b**) C, H, Fe, N, O (**c**) C, H, I, N, O (**d**) C, H_2, Fe, N_2, O_2

SAE 1.7 A certain material has a fixed composition of S and Cl atoms regardless of its source. Which of the following statements about the material is *true*? (**a**) The material is a homogeneous mixture. (**b**) The material contains atoms of silicon and chlorine. (**c**) The material must contain equal numbers of S and Cl atoms. (**d**) The material is a heterogeneous mixture. (**e**) The material is a compound that contains two elements.

1.3 | Properties of Matter

Learning Objectives

When you finish Section 1.3, you should be able to:

- Distinguish between chemical and physical properties, and between intensive and extensive properties.
- Differentiate between chemical and physical changes.
- Describe how filtration, distillation, and chromatography can be used to separate mixtures of substances.

Every substance has unique properties. For example, the properties listed in Table 1.2 allow us to distinguish hydrogen, oxygen, and water from one another. The properties of a substance include everything that describes the substance, such as its color, its physical state, its mass, its ability to react with other substances, and numerous other characteristics. In this section, we look more closely at the types of properties that we typically use in describing substances

Types of Properties of Substances

The properties of matter can be categorized as physical or chemical. **Physical properties** can be observed without changing the identity and composition of the substance. These properties include color, odor, density, melting point, boiling point, and hardness. **Chemical properties** describe the way a substance may change, or *react*, to form other substances. A common chemical property is flammability, the ability of a substance to burn in the presence of oxygen.

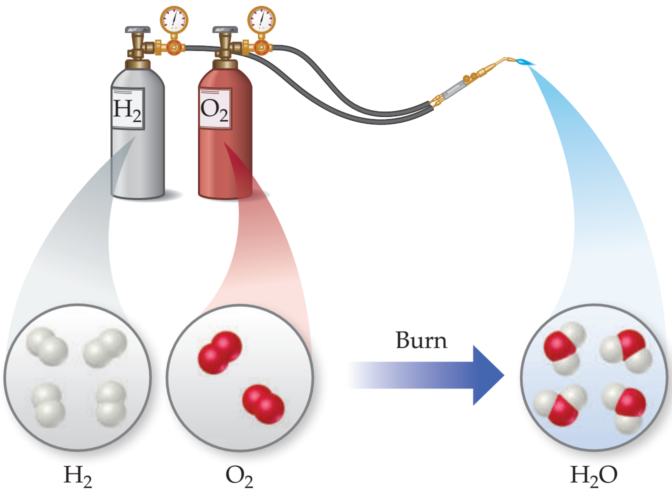
The properties of substances are further separated into two categories depending on whether the property depends on how much of the substance is being considered. Some properties, such as temperature and melting point, are *intensive properties*. **Intensive properties** do *not* depend on the amount of sample being examined and are particularly useful in chemistry because many intensive properties can be used to *identify* substances. **Extensive properties**, such as mass and volume, depend on the amount of sample. Extensive properties relate to the *amount* of substance present.

Physical and Chemical Changes

The changes substances undergo are either physical or chemical. During a **physical change**, a substance changes its physical appearance but not its composition: It is the same substance before and after the change. The evaporation of water is a physical change. When water evaporates, it changes from the liquid state to the gas state, but it is still composed of water molecules, as depicted in Figure 1.3. All **changes of state** (for example, from liquid to gas or from liquid to solid) are physical changes.

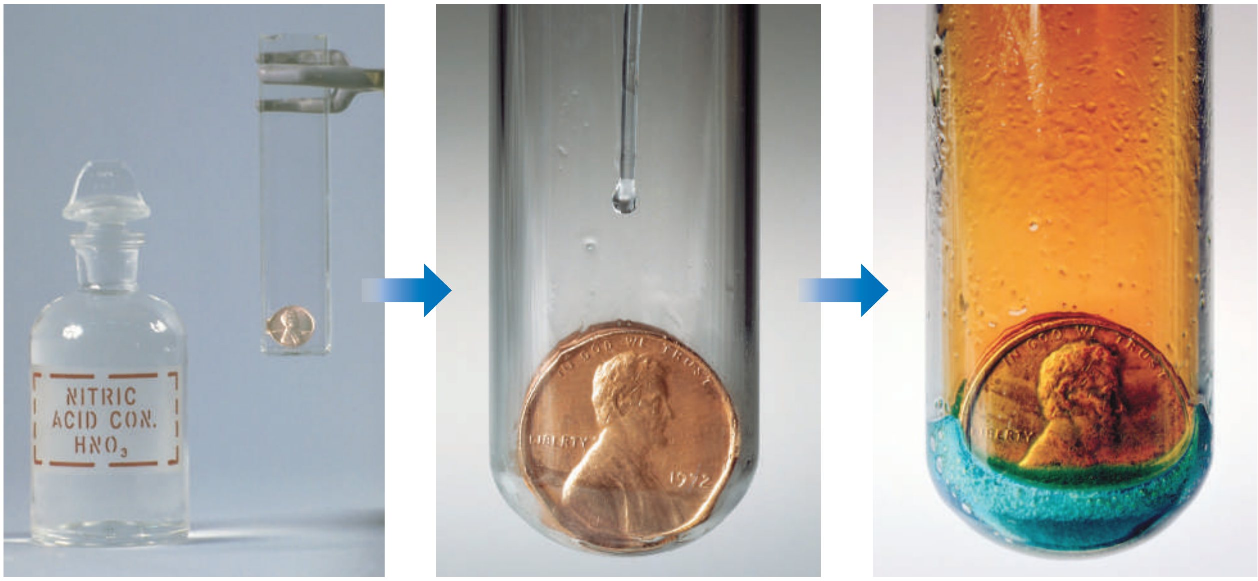
In a **chemical change** (also called a **chemical reaction**), a substance is transformed into a chemically different substance. When hydrogen burns in air, for example, it undergoes a chemical change because it combines with oxygen to form water (**Figure 1.9**).

Chemical changes can be dramatic. In the account given in **Figure 1.10**, Ira Remsen (1846–1927), author of a popular chemistry text, describes his first experiences with chemical reactions.



▲ **Figure 1.9 A chemical reaction.**

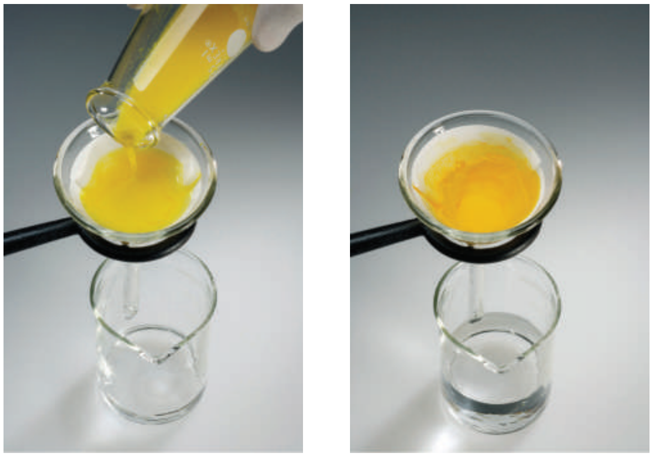
> While reading a textbook of chemistry, I came upon the statement "nitric acid acts upon copper," and I determined to see what this meant. Having located some nitric acid, I had only to learn what the words "act upon" meant. In the interest of knowledge I was even willing to sacrifice one of the few copper cents then in my possession. I put one of them on the table, opened a bottle labeled "nitric acid," poured some of the liquid on the copper, and prepared to make an observation. But what was this wonderful thing which I beheld? The cent was already changed, and it was no small change either. A greenish-blue liquid foamed and fumed over the cent and over the table. The air became colored dark red. How could I stop this? I tried by picking the cent up and throwing it out the window. I learned another fact: nitric acid acts upon fingers. The pain led to another unpremeditated experiment. I drew my fingers across my trousers and discovered nitric acid acts upon trousers. That was the most impressive experiment I have ever performed. I tell of it even now with interest. It was a revelation to me. Plainly the only way to learn about such remarkable kinds of action is to see the results, to experiment, to work in the laboratory.



▲ **Figure 1.10 The chemical reaction between a copper penny and nitric acid.** The dissolved copper produces the blue-green solution; the reddish-brown gas produced is nitrogen dioxide.

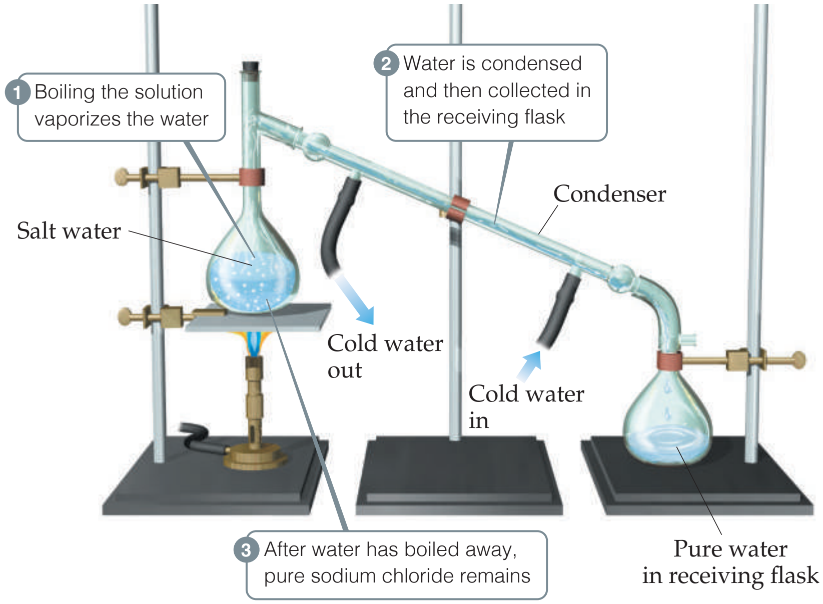
Separation of Mixtures

We can separate a mixture into its components by taking advantage of differences in their properties. For example, a heterogeneous mixture of iron filings and gold filings could be sorted by color into iron and gold. A less tedious approach would be to use a magnet to attract the iron filings, leaving the gold ones behind. We can also take advantage of an important chemical difference between these two metals: Many acids dissolve iron but not gold. Thus, if we put our mixture into an appropriate acid, the acid would dissolve the iron and the solid gold would be left behind. The two could then be separated by **filtration** (Figure 1.11). We would have to use other chemical reactions, which we describe later, to transform the dissolved iron back into metal.



◀ **Figure 1.11 Separation by filtration.** A mixture of a solid and a liquid is poured through filter paper. The liquid passes through the paper while the solid remains on the paper.

▶ **Figure 1.12** **Distillation.** Apparatus for separating a sodium chloride solution (salt water) into its components.

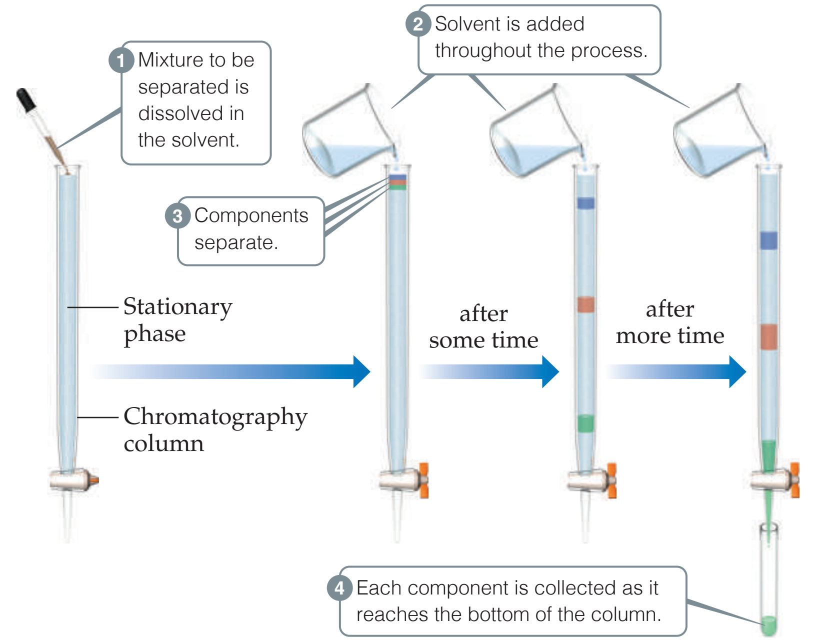


① Boiling the solution vaporizes the water
② Water is condensed and then collected in the receiving flask
Condenser
Salt water
Cold water out
Cold water in
③ After water has boiled away, pure sodium chloride remains
Pure water in receiving flask

An important method of separating the components of a homogeneous mixture is **distillation**, a process that depends on the different abilities of substances to form gases. For example, if we boil a solution of salt and water, the water evaporates, forming a gas, and the salt is left behind. The gaseous water can be converted back to a liquid on the walls of a condenser, as shown in **Figure 1.12**.

The differing abilities of substances to adhere to the surfaces of solids can also be used to separate mixtures. For example, a mixture of substances can be separated by placing a sample of the mixture at the top of a column filled with a porous solid, as shown in **Figure 1.13**. When a suitable solvent is added to the top of the column, the mixture separates into its different components. This separation technique is called **chromatography** (literally "the writing of colors").

Go Figure Is the separation of the mixture shown here a physical or chemical process?



① Mixture to be separated is dissolved in the solvent.
② Solvent is added throughout the process.
③ Components separate.
Stationary phase
Chromatography column
after some time
after more time
④ Each component is collected as it reaches the bottom of the column.

Self-Assessment Exercises

SAE 1.8 Imagine you have a gallon of the substance called *methanol*. Under usual conditions, methanol is a flammable colorless liquid. Which of the following statements about the properties of methanol is *correct*? (**a**) The fact that methanol is colorless is a chemical property. (**b**) The mass of the gallon of methanol is an intensive property. (**c**) The fact that methanol is flammable is a physical property. (**d**) The temperature at which the methanol freezes is an intensive property.

SAE 1.9 Each of the following describes either a physical change or a chemical change of a substance:

(**i**) An iron nail rusts when exposed to damp air.
(**ii**) Water vapor condenses on a cold window to form frost.
(**iii**) Plants make sugar from carbon dioxide and water.

Which of these processes are *chemical* changes? (**a**) Only one of the three is a chemical change (**b**) i and ii (**c**) i and iii (**d**) ii and iii (**e**) All three are chemical changes.

SAE 1.10 Which of the following statements about separation techniques is *incorrect*? (**a**) Filtration can be used to separate a solid substance from a liquid. (**b**) Distillation is a technique that depends on the differences in the evaporation of different substances. (**c**) Solid A dissolves in water and solid B does not dissolve in water. After adding a mixture of the two solids to water, filtration would be an effective way of separating a mixture of solids A and B. (**d**) Chromatography is a technique that depends on the differences in the rate of travel of different substances through a solid medium. (**e**) Chromatography can be used to separate a compound into its elements.

1.4 The Nature of Energy

All objects in the universe are made of matter, but matter alone is not enough to describe the behavior of the world around us. The water in an alpine lake and a pot of boiling water are both made from the same substance, but your body will experience a very different sensation if you put your hand in each. The difference between the two is their energy content; boiling water has more energy than chilled water. To understand chemistry, we must also understand energy and the changes in energy that accompany chemical processes.

Learning Objectives

When you finish Section 1.4, you should be able to:

- Describe the concepts of *energy*, *work*, and *heat.*
- Distinguish between *kinetic* and *potential* energy.

Work and Heat

Unlike matter, energy does not have mass and cannot be held in our hands, but its effects can be observed and measured. **Energy** is defined as *the capacity to do work or transfer heat*. Both work and heat are means by which energy is transferred from one object to another. **Work** is *the energy transferred when a force exerted on an object causes a displacement of that object*. **Heat** is *the energy transferred to cause the temperature of an object to increase*. The concepts of work and heat are illustrated in the examples shown in **Figure 1.14**.

Although the temperature of an object is intuitive to most people, the definition of work is less apparent. We define work, w, as the product of the force exerted on the object, F, and the distance, d, that it moves:

$$w = F \times d \qquad [1.1]$$

The **force** F is defined as any push or pull exerted on the object.* Familiar examples include gravity and the attraction between opposite poles of a bar magnet. It takes work to lift an object off of the floor or to pull apart two magnets that have come together at the opposite poles. When you type on a keyboard, you are doing work on the keys as they are displaced by the force of your fingers.

Kinetic Energy and Potential Energy

To understand energy, we need to grasp its two fundamental forms, kinetic energy and potential energy. Objects, whether they are automobiles, baseballs, or molecules, can possess **kinetic energy**, the energy of *motion*. The magnitude of the kinetic energy, E_k, of an object depends on its mass, m, and velocity, v:

---

*In using this equation, only the component of the force that is acting in the same direction as the distance traveled is used. That will generally be the case for problems we will encounter in this chapter.

$$E_k = \frac{1}{2}mv^2 \qquad [1.2]$$

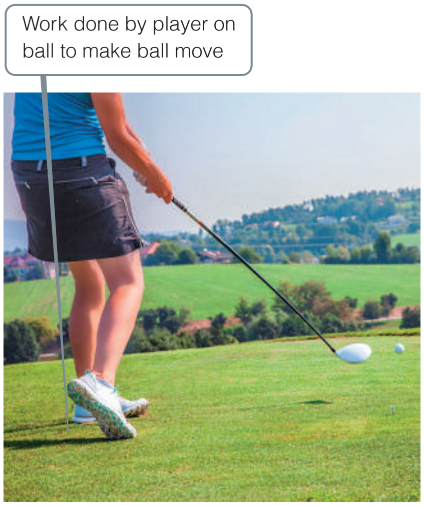
Thus, the kinetic energy of an object increases as its velocity or speed* increases. For example, a car has greater kinetic energy moving at 65 miles per hour (mi/h) than it does at 25 mi/h. For a given velocity, the kinetic energy increases with increasing mass. Thus, a large truck traveling at 65 mi/h has greater kinetic energy than a motorcycle traveling at the same velocity because the truck has the greater mass.

In chemistry, we are interested in the kinetic energy of atoms and molecules. Although these particles are too small to be seen, they have mass and are in motion, so they possess kinetic energy. When a substance is heated, be it a pot of water on the stove or a metal bench sitting in the Sun, the atoms and molecules in that substance gain kinetic energy and their average speed increases. Hence, we see that the transfer of heat is simply the transfer of kinetic energy at the molecular level. We return to this concept in later chapters of the book.

All other forms of energy—the energy stored in a stretched spring, in a weight held above your head, or in a chemical bond—are classified as potential energy. An object has **potential energy** by virtue of its position relative to other objects. Potential energy is, in essence, the "stored" energy that arises from the attractions and repulsions an object experiences in relation to other objects.

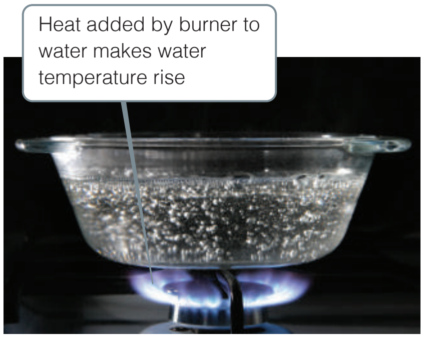
We are familiar with many instances in which potential energy is converted into kinetic energy. For example, think of a cyclist poised at the top of a hill (**Figure 1.15**). Because of the attractive force of gravity, the gravitational potential energy of the bicycle is greater at the top of the hill than at the bottom. As a result, the bicycle easily rolls down the hill with increasing speed. As it does so, gravitational potential energy is converted into kinetic energy. The gravitational potential energy decreases as the bicycle rolls down the hill, while at the same time its kinetic energy increases as it picks up speed (Equation 1.2). This example illustrates that kinetic and potential energy are interconvertible.

Gravitational forces play a negligible role in the ways that atoms and molecules interact with one another. Forces that arise from electrical charges are more important when dealing with atoms and molecules. One of the most important forms of potential



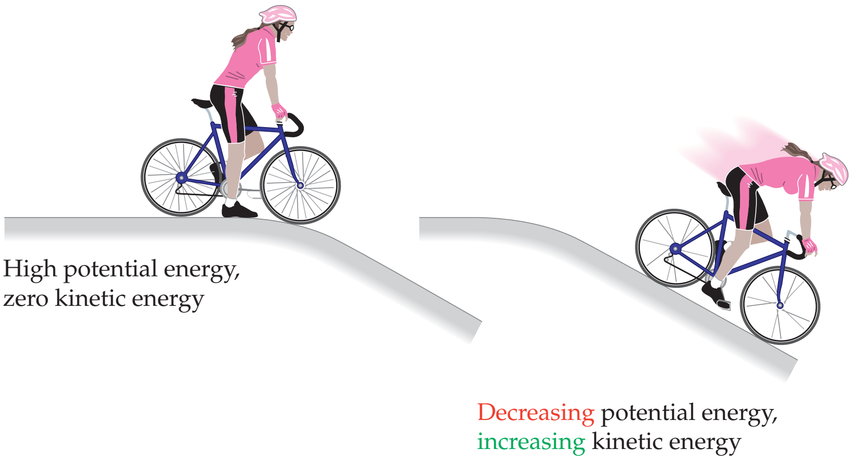
Work done by player on ball to make ball move

(a)



(b)

▲ **Figure 1.14** **Work and heat, two forms of energy.** (**a**) *Work* is energy used to cause an object to move against an opposing force. (**b**) *Heat* is energy used to increase the temperature of an object.



High potential energy, zero kinetic energy
Decreasing potential energy, increasing kinetic energy

▲ **Figure 1.15** **Potential energy and kinetic energy.** The potential energy initially stored in the motionless bicycle and rider at the top of the hill is converted to kinetic energy as the bicycle moves down the hill and loses potential energy.

---

*Strictly speaking, velocity is a *vector* quantity that has a direction—that is, it tells you how fast an object is moving and in what direction. Speed is a *scalar* quantity that tells you how fast an object is moving but not the direction of the motion. Unless otherwise stated, we will not be concerned with the direction of motion, so velocity and speed are used interchangeably in this book.

energy in chemistry is *electrostatic potential energy*, which arises from the interactions between charged particles. Opposite charges attract each other, whereas like charges repel. The strength of this interaction increases as the magnitudes of the charges increase, and it decreases as the distance between charges increases. We return to electrostatic energy several times throughout the book.

One of our goals in chemistry is to relate the energy changes seen in the macroscopic world to the kinetic or potential energy of substances at the molecular level. Many substances, fuels for example, release energy when they react. The *chemical energy* of a fuel is due to the potential energy stored in the arrangements of its atoms. As we explain in later chapters, *chemical energy is released when bonds between atoms are formed, and it is consumed when bonds between atoms are broken*. When a fuel burns, some bonds are broken and others are formed, but the net effect is to convert chemical potential energy to thermal energy, the energy associated with temperature.

Self-Assessment Exercises

SAE 1.11 Which of the following statements about energy, work, and heat is *false*? (**a**) Energy can be classified into two fundamental forms: kinetic energy and potential energy. (**b**) Heat is energy transferred to increase the temperature of an object. (**c**) Energy is the capacity to do work or transfer heat. (**d**) Work causes the displacement of an object. (**e**) Energy has mass and occupies space.

SAE 1.12 A rocket takes off from the surface of Earth and accelerates into the sky. Which of the following correctly describes the changes in the kinetic and gravitational potential energy of the rocket as it takes off? (**a**) Its kinetic energy decreases and its gravitational potential energy decreases. (**b**) Its kinetic energy increases and its gravitational potential energy decreases. (**c**) Its kinetic energy decreases and its gravitational potential energy increases. (**d**) Its kinetic energy increases and its gravitational potential energy increases. (**e**) The kinetic and gravitational potential energies of the rocket are unchanged.

SAE 1.13 Consider the following three vehicles in motion:

- (**i**) A compact car that weighs 2000 pounds and is traveling at 40 miles per hour.
- (**ii**) A medium-sized car that weighs 3000 pounds and is traveling at 40 miles per hour.
- (**iii**) A truck that weighs 4000 pounds and is traveling at 20 miles per hour.

Which of the following is the correct ordering of the vehicles from smallest to largest kinetic energy? (**a**) iii < i < ii (**b**) i < ii < iii (**c**) i = iii < ii (**d**) i < iii < ii (**e**) ii < iii = i

CHEMISTRY AND SUSTAINABILITY An Introduction

As the global population grows, we continue to consume Earth's resources and put strains on the capacity of the human race to provide essential needs to sustain its existence. The notion of *sustainability* is used to describe the intersection of economic, social, and environmental factors to determine the best ways in which we can exist on Earth while being responsible stewards of it.

In 1991, the World Conservation Union, the United Nations Environment Programme, and the World Wildlife Fund for Nature published a report entitled "Caring for the Earth: A Strategy for Sustainable Living."* In this report, they proposed a set of principles for a sustainable society, which began with the following sentences: "Living sustainably depends on accepting a duty to seek harmony with other people and with nature. The guiding rules are that people must share with each other and care for the Earth. Humanity must take no more from nature than nature can replenish." These guiding principles have become increasingly relevant in a world that is subject to greater climate change, food shortages, increasing scarcity of clean water, and global pandemics.

Undeniably, some applications of chemistry have had negative impacts on sustainability, such as industrial chemical spills, the use of chemical substances that were later found to be toxic, and the generation of chemical waste as technology has advanced. However, chemistry has also had some of the most positive effects in increasing the sustainability of our world. It promises even more as we head to the future.

Sustainability entails more than scientific and technological advances. In 2016, the United Nations introduced its 17 Sustainable Development Goals (**Figure 1.16**). These far-reaching goals address important issues of social justice and global economic issues. Chemistry, as the central science, has the capacity to improve global conditions in many of these important areas and will therefore have a major role in achieving these ambitious goals.

In this edition of our textbook, we are introducing a new set of feature boxes entitled "Chemistry and Sustainability." In these boxes, we highlight some of the ways in which applications of chemistry and related fields (such as chemical engineering and materials science) are making ours a more sustainable planet. We also present some of the new developments that promise to enhance sustainability in the near future. Many of you who are students of chemistry now will likely end up as practitioners of the chemical sciences and may very well end up working on these exciting new discoveries that make ours a better, and more sustainable, world. We hope you find these examples both instructive and inspiring.

1.5 | Units of Measurement

Learning Objectives

When you finish Section 1.5, you should be able to:

- Identify the seven base units and the common prefixes used in the *metric system.*
- Convert temperatures between the Fahrenheit, Celsius, and Kelvin scales.
- Distinguish metric base units from derived units, such as volume.
- Interconvert among mass, volume, and density, given two of the three quantities.
- Calculate energy quantities in joules.

Many properties of matter are *quantitative;* that is, they are associated with numbers. When a number represents a measured quantity, the units of that quantity must be specified. To say that the length of a pencil is 17.5 is meaningless. Expressing the number with its units, 17.5 centimeters (cm), properly specifies the length. In this section, we look more closely at the units we use for measurement in science.

The Metric System and SI Units

The units used for scientific measurements are those of the **metric system**, developed in France during the late eighteenth century. Most countries use the metric system as their system of measurement. The United States has traditionally used the English system, although use of the metric system has become more common (Figure 1.17).

In 1960, an international agreement was reached specifying a particular choice of metric units for use in scientific measurements. These preferred units are called **SI units**, after the French *Système International d'Unités*. This system has seven *base units* from which all other units are derived (Table 1.3). In this chapter , we discuss the SI base units for length, mass, and temperature. The SI units for other measures, such as volume, can be derived from these fundamental base units.

With SI units, prefixes are used to indicate decimal fractions or multiples of various units. For example, the prefix *milli-* represents a 10^{-3} fraction, one-thousandth, of a unit: A milligram (mg) is 10^{-3} gram (g), a millimeter (mm) is 10^{-3} meter (m), and so forth. Table 1.4 lists the prefixes used in SI units; the prefixes most commonly encountered in chemistry are kilo-, centi-, milli-, micro-, and nano. In using SI units and in working

TABLE 1.3 SI Base Units

Physical Quantity	Name of Unit	Abbreviation
Length	Meter	m
Mass	Kilogram	kg
Temperature	Kelvin	K
Time	Second	s or sec
Amount of substance	Mole	mol
Electric current	Ampere	A or amp
Luminous intensity	Candela	cd

TABLE 1.4 Prefixes Used in the Metric System and with SI Units

Prefix	Abbreviation	Meaning	Example	
Peta	P	10^{15}	1 petawatt (PW)	$= 1 \times 10^{15}$ watts[a]
Tera	T	10^{12}	1 terawatt (TW)	$= 1 \times 10^{12}$ watts
Giga	G	10^{9}	1 gigawatt (GW)	$= 1 \times 10^{9}$ watts
Mega	M	10^{6}	1 megawatt (MW)	$= 1 \times 10^{6}$ watts
Kilo	k	10^{3}	1 kilowatt (kW)	$= 1 \times 10^{3}$ watts
Deci	d	10^{-1}	1 deciwatt (dW)	$= 1 \times 10^{-1}$ watt
Centi	c	10^{-2}	1 centiwatt (cW)	$= 1 \times 10^{-2}$ watt
Milli	m	10^{-3}	1 milliwatt (mW)	$= 1 \times 10^{-3}$ watt
Micro	μ[b]	10^{-6}	1 microwatt (μW)	$= 1 \times 10^{-6}$ watt
Nano	n	10^{-9}	1 nanowatt (nW)	$= 1 \times 10^{-9}$ watt
Pico	p	10^{-12}	1 picowatt (pW)	$= 1 \times 10^{-12}$ watt
Femto	f	10^{-15}	1 femtowatt (fW)	$= 1 \times 10^{-15}$ watt
Atto	a	10^{-18}	1 attowatt (aW)	$= 1 \times 10^{-18}$ watt
Zepto	z	10^{-21}	1 zeptowatt (zW)	$= 1 \times 10^{-21}$ watt

[a] The watt (W) is the SI unit of power, which is the rate at which energy is either generated or consumed. The SI unit of energy is the joule (J); $1\ \text{J} = 1\ \text{kg} \cdot \text{m}^2/\text{s}^2$ and $1\ \text{W} = 1\ \text{J/s}$.

[b] Greek letter mu, pronounced "mew."

problems throughout this text, you must be comfortable using exponential notation. If you are unfamiliar with exponential notation or want to review it, refer to Appendix A.1.

Although non-SI units are being phased out, some are still commonly used by scientists. Whenever we first encounter a non-SI unit in the text, the SI unit will also be given. The relationships between the non-SI and SI units we use most frequently in this text appear on the back inside cover. We discuss how to convert from one to the other in Section 1.7.

Length and Mass

The SI base unit of *length* is the meter, which is a distance slightly longer than a yard. **Mass*** is a measure of the amount of material in an object. The SI base unit of mass is the kilogram (kg), which is equal to about 2.2 pounds (lb). This base unit is unusual because it uses a prefix, *kilo-*, instead of the word *gram* alone. We obtain other units for mass by adding prefixes to the word *gram*.

Sample Exercise 1.2

Using SI Prefixes

What is the name of the unit that equals (**a**) 10^{-9} gram, (**b**) 10^{-6} second, (**c**) 10^{-3} meter?

SOLUTION

We can find the prefix related to each power of ten in Table 1.4: (**a**) nanogram, ng; (**b**) microsecond, μs; (**c**) millimeter, mm.

Practice Exercise

(**a**) How many picometers are there in 1 m? (**b**) Express 6.0×10^3 m using a prefix to replace the power of ten. (**c**) Use exponential notation to express 4.22 mg in grams. (**d**) Which of the following lengths is greatest: 12.0 m, 2.0×10^3 mm, 1.5×10^{-3} km, or 1.8×10^{10} nm?

Temperature

Temperature, a measure of the hotness or coldness of an object, is a physical property that determines the direction of heat flow. Heat always flows spontaneously from a substance at higher temperature to one at lower temperature. Thus, the influx of heat we feel when we touch a hot object tells us that the object is at a higher temperature than our hand.

The temperature scales commonly employed in science are the Celsius and Kelvin scales. The **Celsius scale** was originally based on the assignment of 0 °C to the freezing point of water and 100 °C to its boiling point at sea level (**Figure 1.18**).

The **Kelvin scale** is the SI temperature scale, and the SI unit of temperature is the *kelvin* (K). Zero on the Kelvin scale is the temperature at which all thermal motion ceases, a temperature referred to as **absolute zero**. On the Celsius scale, absolute zero has the value −273.15 °C. The Celsius and Kelvin scales have equal-sized units; that is, a kelvin is the same size as a degree Celsius. Thus, the Kelvin and Celsius scales are related according to

$$K = {}^\circ C + 273.15 \qquad [1.3]$$

The freezing point of water, 0 °C, is 273.15 K (Figure 1.18). Notice that we do not use a degree sign (°) with temperatures on the Kelvin scale.

The common temperature scale in the United States is the *Fahrenheit scale*, which is not generally used in science. Water freezes at 32 °F and boils at 212 °F. The Fahrenheit and Celsius scales are related according to

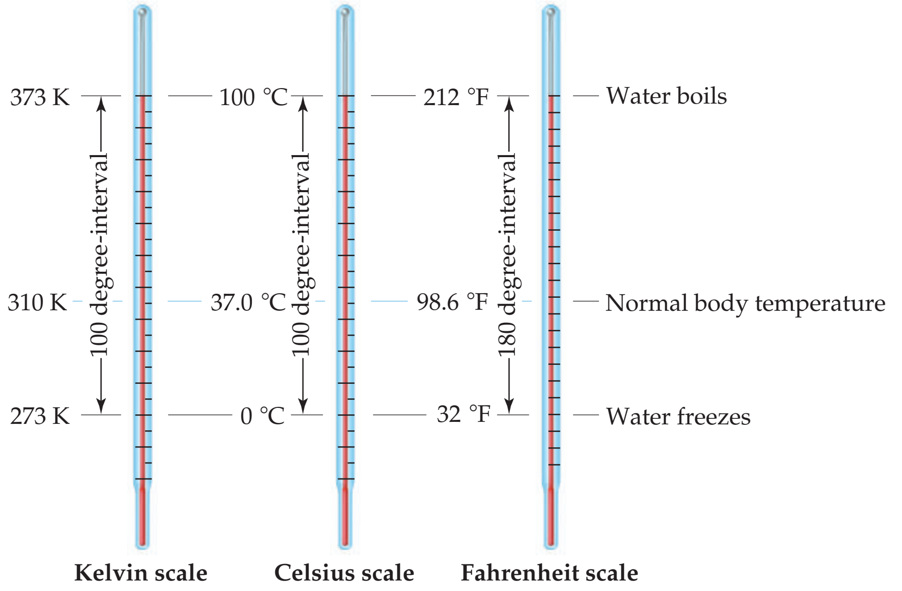
$${}^\circ C = \frac{5}{9}({}^\circ F - 32) \quad \text{or} \quad {}^\circ F = \frac{9}{5}({}^\circ C) + 32 \qquad [1.4]$$

---

*Mass and weight are not the same thing. Mass is a measure of the amount of matter, whereas weight is the force exerted on this mass by gravity. For example, an astronaut weighs less on the Moon than on Earth because the Moon's gravitational force is less than Earth's. The astronaut's mass on the Moon, however, is the same as it is on Earth.

Go Figure

True or false: The "size" of a degree on the Celsius scale is the same as the "size" of a degree on the Kelvin scale.



▲ **Figure 1.18** **Comparison of the Kelvin, Celsius, and Fahrenheit temperature scales.**

Derived SI Units

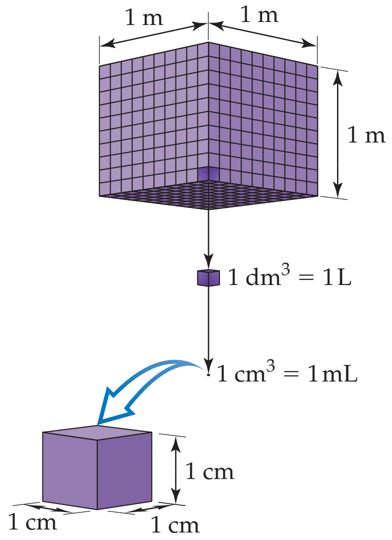
The SI base units are used to formulate *derived units*. A **derived unit** is obtained by multiplication or division of one or more of the base units. We begin with the defining equation for a quantity and, then substitute the appropriate base units. For example, *speed* is defined as the ratio of distance traveled to elapsed time. Thus, the derived SI unit for speed is the SI unit for distance (length), m, divided by the SI unit for time, s, which gives m/s, read "meters per second." Two common derived units in chemistry are those for volume and density.

The *volume* of a cube is its length cubed, length^3. Thus, the derived SI unit of volume is the SI unit of length, m, raised to the third power. The cubic meter, m^3, is the volume of a cube that is 1 m on each edge (**Figure 1.19**). Smaller units, such as cubic centimeters, cm^3 (sometimes written cc), are more frequently used in chemistry. The volume unit most commonly used in chemistry is the *liter* (L), which equals a cubic decimeter, dm^3, and is slightly larger than a quart. (The liter is the first metric unit we have encountered that is *not* an SI unit.) There are 1000 milliliters (mL) in a liter, and 1 mL is the same volume as 1 cm^3: 1 mL = 1 cm^3.

In the lab, you will likely use the devices in **Figure 1.20** to measure and deliver volumes of liquids. Syringes, burettes, and pipettes deliver amounts of liquids with more precision than graduated cylinders. Volumetric flasks are used to contain specific volumes of liquid.

Go Figure

How many 1-L bottles are required to contain 1 m^3 of liquid?



▲ **Figure 1.19** **Volume relationships.** The volume occupied by a cube 1 m on each edge is one cubic meter, 1 m^3. Each cubic meter contains 1000 dm^3, 1 m^3 = 1000 dm^3. One liter is the same volume as one cubic decimeter, 1 L = 1 dm^3. Each cubic decimeter contains 1000 cubic centimeters, 1 dm^3 = 1000 cm^3. One cubic centimeter equals one milliliter, 1 cm^3 = 1 mL.

Sample Exercise 1.3

Converting Units of Temperature

A weather forecaster predicts the temperature will reach 30 °C. What is this temperature (**a**) in K and (**b**) °F?

SOLUTION

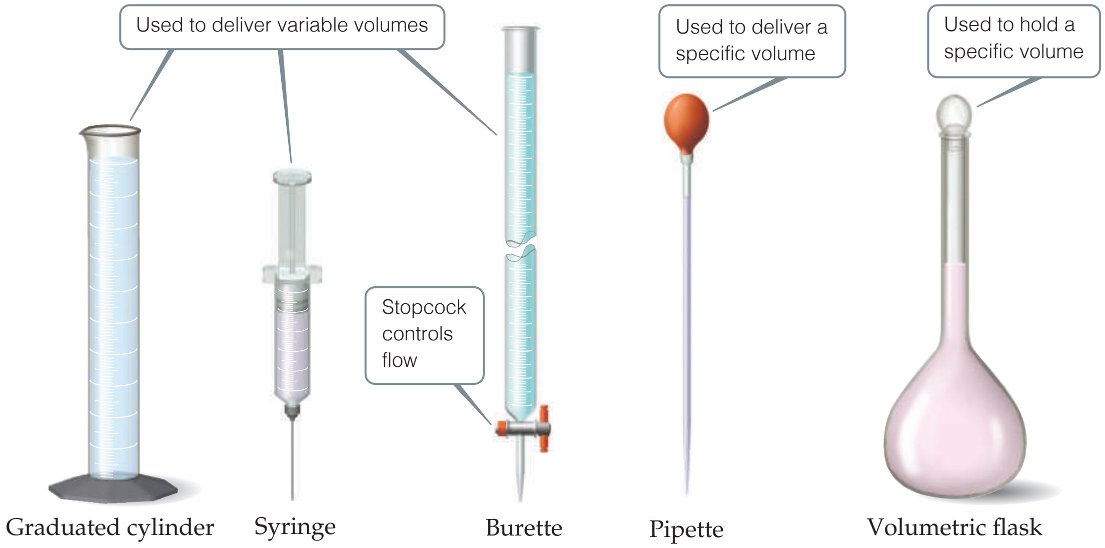
(**a**) Using Equation 1.3, we have K = 30 + 273 = 303 K.

(**b**) Using Equation 1.4, we have

$$°\text{F} = \frac{9}{5}(30) + 32 = 54 + 32 = 86\,°\text{F}.$$

Practice Exercise

Ethylene glycol, the major ingredient in antifreeze, freezes at 260 K. What is the freezing point in (**a**) °C and (**b**) °F?



Used to deliver variable volumes
Used to deliver a specific volume
Used to hold a specific volume
Stopcock controls flow
Graduated cylinder
Syringe
Burette
Pipette
Volumetric flask

▶ **Figure 1.20** **Common volumetric glassware.**

TABLE 1.5 Densities of Selected Substances at 25 °C

Substance	Density (g/cm^3)
Air	0.001
Balsa wood	0.16
Ethanol	0.79
Olive oil	0.92
Water	1.00
Ethylene glycol	1.09
Table sugar	1.59
Table salt	2.16
Iron	7.9
Gold	19.32

Density is defined as the amount of mass in a unit volume of a substance:

$$\text{density} = \frac{\text{mass}}{\text{volume}} \qquad [1.5]$$

The densities of solids and liquids are commonly expressed in either grams per cubic centimeter (g/cm^3) or grams per milliliter (g/mL). The densities of some common substances are listed in **Table 1.5**. It is no coincidence that the density of water is 1.00 g/mL; the gram was originally defined as the mass of 1 mL of water at a specific temperature. Because most substances change volume when they are heated or cooled, densities are temperature dependent, and so temperature should be specified when reporting densities. If no temperature is reported, we assume 25 °C, close to normal room temperature.

The terms *density* and *weight* are sometimes confused. A person who says that iron weighs more than air generally means that iron has a higher density than air—1 kg of air has the same mass as 1 kg of iron, but the iron occupies a smaller volume, thereby giving it a higher density. If we combine two liquids that do not mix, such

Sample Exercise 1.4

Determining Density and Using Density to Determine Volume or Mass

(**a**) Calculate the density of mercury if 1.00×10^2 g occupies a volume of 7.36 cm^3.

(**b**) Calculate the volume of 65.0 g of liquid methanol (wood alcohol) if its density is 0.791 g/mL.

(**c**) What is the mass in grams of a cube of gold (density = 19.32 g/cm^3) if the length of the cube is 2.00 cm?

SOLUTION

(**a**) We are given mass and volume, so Equation 1.3 yields

$$\text{Density} = \frac{\text{mass}}{\text{volume}} = \frac{1.00 \times 10^2\ \text{g}}{7.36\ \text{cm}^3} = 13.6\ \text{g/cm}^3$$

(**b**) Solving Equation 1.3 for volume and then using the given mass and density gives

$$\text{Volume} = \frac{\text{mass}}{\text{density}} = \frac{65.0\ \cancel{\text{g}}}{0.791\ \cancel{\text{g}}/\text{mL}} = 82.2\ \text{mL}$$

(**c**) We can calculate the mass from the volume of the cube and its density. The volume of a cube is given by its length cubed:

$$\text{Volume} = (2.00\ \text{cm})^3 = (2.00)^3\ \text{cm}^3 = 8.00\ \text{cm}^3$$

Solving Equation 1.3 for mass and substituting the volume and density of the cube, we have

$$\text{Mass} = \text{volume} \times \text{density} = (8.00\ \cancel{\text{cm}^3})(19.32\ \text{g}/\cancel{\text{cm}^3}) = 155\ \text{g}$$

▶ **Practice Exercise**

(**a**) Calculate the density of a 374.5-g sample of copper if it has a volume of 41.8 cm^3. (**b**) A student needs 15.0 g of ethanol for an experiment. If the density of ethanol is 0.789 g/mL, how many milliliters of ethanol are needed?

as olive oil and water, the less dense liquid (in this case the oil) will float on the denser liquid (the water).

Units of Energy

The SI unit for energy is the **joule** (pronounced “jool”), J, in honor of James Joule (1818–1889), a British scientist who investigated work and heat. If we return to Equation 1.2, where kinetic energy was defined, we see that the units of energy are (mass) × (velocity)^2. Thus, it follows that joules are a derived unit, $1\text{ J} = 1\,(\text{kg}) \times (\text{m/s})^2 = 1\text{ kg-m}^2/\text{s}^2$. Numerically, a 2-kg mass moving at a velocity of 1 m/s possesses a kinetic energy of 1 J:

$$E_k = \frac{1}{2}mv^2 = \frac{1}{2}(2\text{ kg})(1\text{ m/s})^2 = 1\text{ kg-m}^2/\text{s}^2 = 1\text{ J}$$

Because a joule is not a very large amount of energy, we often use *kilojoules* (kJ) in discussing the energies associated with chemical reactions. For example, the amount of heat released when hydrogen and oxygen react to form 1 g of water is 16 kJ.

It is still quite common in chemistry, biology, and biochemistry to find energy changes associated with chemical reactions expressed in the non-SI unit of calories. A **calorie** (cal) was originally defined as the amount of energy required to raise the temperature of 1 g of water from 14.5 to 15.5 °C. It has since been defined in terms of a joule:

$$1\text{ cal} = 4.184\text{ J (exactly)}$$

A related energy unit that is familiar to anyone who has read a food label is the nutritional *Calorie* (note the capital C), which is 1000 times larger than *calorie* with a lowercase c: 1 Cal = 1000 cal = 1 kcal.

Sample Exercise 1.5

Identifying and Calculating Energy Changes

A standard propane (C_3H_8) tank used in an outdoor grill holds approximately 9.0 kg of propane. When the grill is operating, propane reacts with oxygen to form carbon dioxide and water. For every gram of propane that reacts with oxygen in this way, 46 kJ of energy is released as heat. (**a**) How much energy is released if the entire contents of the propane tank react with oxygen? (**b**) As the propane reacts, does the potential energy stored in chemical bonds increase or decrease? (**c**) If you were to store an equivalent amount of potential energy by pumping water to an elevation of 75 m above the ground, what mass of water would be needed? (Note: The force due to gravity acting on the water, which is the water's weight, is $F = m \times g$, where m is the mass of the object and g is the gravitational constant, $g = 9.8\text{ m/s}^2$.)

SOLUTION

(**a**) We can calculate the amount of energy released from the propane as heat by converting the mass of propane from kg to g and then using the fact that 46 kJ of heat are released per gram:

$$E = 9.0\,\cancel{\text{kg}} \times \frac{1000\,\cancel{\text{g}}}{1\,\cancel{\text{kg}}} \times \frac{46\text{ kJ}}{1\,\cancel{\text{g}}} = 4.1 \times 10^5\text{ kJ} = 4.1 \times 10^8\text{ J}$$

(**b**) When propane reacts with oxygen, the potential energy stored in the chemical bonds is converted to an alternate form of energy, heat. Therefore, the potential energy stored as chemical energy must decrease.

(**c**) The amount of work done to pump the water to a height of 75 m can be calculated using Equation 1.1:

$$w = F \times d = (m \times g) \times d$$

Equation 1.1 can then be rearranged to solve for the mass of water:

$$m = \frac{w}{g \times d} = \frac{4.1 \times 10^8\text{ J}}{(9.8\text{ m/s}^2)(75\text{ m})} = \frac{4.1 \times 10^8\text{ kg-}\cancel{\text{m}^2}/\cancel{\text{s}^2}}{(9.8\,\cancel{\text{m}}/\cancel{\text{s}^2})(75\,\cancel{\text{m}})}$$
$$= 5.6 \times 10^5\text{ kg}$$

At 25 °C, this mass of water would have a volume of 560,000 L, or roughly 150,000 gallons. Thus, we see that large amounts of potential energy can be stored as chemical energy.

Practice Exercise

A 12-oz vanilla milkshake at a fast-food restaurant contains 547 Calories. What quantity of energy is this in joules?

A CLOSER LOOK The Scientific Method

Where does scientific knowledge come from? How is it acquired? How do we know it is reliable? How do scientists add to it or modify it?

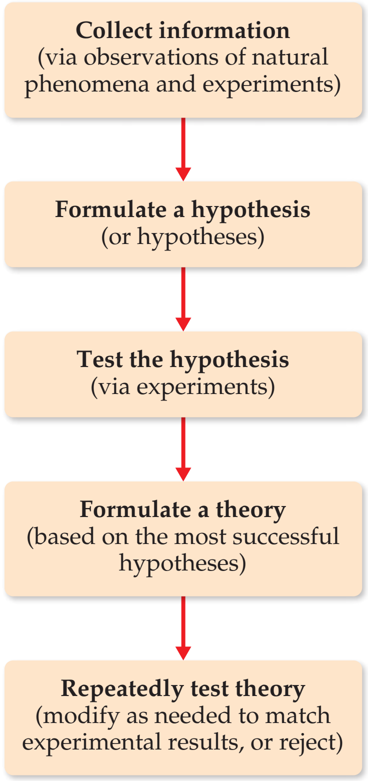
There is nothing mysterious about how scientists work. The first idea to keep in mind is that scientific knowledge is gained through observations of the natural world. A principal aim of the scientist is to organize these observations by identifying patterns and regularity, making measurements, and associating one set of observations with another.

After an observation is made, the next step is to ask *why* nature behaves in the manner we observe. To answer this question, the scientist constructs a model, known as a *hypothesis*, to explain the observations. Initially, the hypothesis is likely to be pretty tentative. There could be more than one reasonable hypothesis. If a hypothesis is correct, then certain results and observations should follow from it. In this way, hypotheses can stimulate the design of experiments to learn more about the system being studied. Scientific creativity comes into play in thinking of hypotheses that are fruitful in suggesting good experiments to do, ones that will shed new light on the nature of the system.

As more information is gathered, the initial hypotheses get winnowed down. Eventually, just one may stand out as most consistent with a body of accumulated evidence. We then begin to call this hypothesis a *theory*, a model that has predictive powers and that accounts for all the available observations. A theory also generally is consistent with other, perhaps larger and more general theories. For example, a theory of what goes on inside a volcano has to be consistent with more general theories regarding heat transfer, chemistry at high temperature, and so forth.

We will encounter many theories as we proceed through this book. Some of them have been found over and over again to be consistent with observations. However, no theory can be proven to be absolutely true. We can treat it as though it is, but there always remains a possibility that there is some respect in which a theory is wrong. A famous example is Isaac Newton's theory of mechanics, which yielded such precise results for the mechanical behavior of matter that no exceptions to it were found before the twentieth century. But Albert Einstein showed that Newton's theory of the nature of space and time is incorrect. Einstein's theory of relativity represented a fundamental shift in how we think of space and time. He predicted where the exceptions to predictions based on Newton's theory might be found. Although only small departures from Newton's theory were predicted, they *were* observed. Einstein's theory of relativity became accepted as the correct model. For most uses, however, Newton's laws of motion are quite accurate enough.

The overall process we have just considered, illustrated in Figure 1.21, is often referred to as *the scientific method*. But there is no single scientific method. Many factors play a role in advancing scientific knowledge. The one unvarying requirement is that our explanations must be consistent with observations and that they must depend solely on natural phenomena.



Collect information
(via observations of natural phenomena and experiments)
Formulate a hypothesis
(or hypotheses)
Test the hypothesis
(via experiments)
Formulate a theory
(based on the most successful hypotheses)
Repeatedly test theory
(modify as needed to match experimental results, or reject)

▲ **Figure 1.21 The scientific method.**

What can we do when we observe nature behaving a certain way and test our theories with additional observations? When nature behaves in a certain way over and over again, under all sorts of different conditions, we can summarize that behavior in a *scientific law*. For example, it has been repeatedly observed that in a chemical reaction there is no change in the total mass of the materials reacting as compared with the materials that are formed; we call this observation the *law of conservation of mass*. It is important to make a distinction between a theory and a scientific law. On the one hand, a scientific law is a statement of what always happens, to the best of our knowledge. A theory, on the other hand, is an *explanation* for what happens. If we discover some law fails to hold true, then we must assume the theory underlying that law is wrong in some way.

SAE 1.18 What is the kinetic energy in J of a 360-kg motorcycle moving at 88 km/h?

(a) 1.1×10^{-1} J
(b) 4.4×10^3 J
(c) 1.1×10^5 J
(d) 2.2×10^5 J
(e) 1.4×10^6 J

1.6 | Uncertainty in Measurement and Significant Figures

Much of what we cover throughout this text involves various quantitative aspects of chemistry. Exploring these quantitative aspects requires that we learn how to properly deal with numbers, whether they are measured quantities or calculated ones. In this section, we begin to examine the rules and vocabulary associated with such quantities.

Exact and Inexact Numbers

Two kinds of numbers are encountered in scientific work: *exact numbers* (those whose values are known exactly) and *inexact numbers* (those whose values have some uncertainty). Most of the exact numbers we will encounter in this book have defined values. For example, there are exactly 12 eggs in a dozen, exactly 1000 g in a kilogram, and exactly 2.54 cm in an inch. The number 1 in any conversion factor, such as 1 m = 100 cm or 1 kg = 2.2046 lb, is an exact number. Exact numbers can also result from counting objects. For example, we can count the exact number of marbles in a jar or the exact number of people in a classroom.

Numbers obtained by measurement are always *inexact*. The equipment used to measure quantities always has inherent limitations (equipment errors), and there are differences in how different people make the same measurement (human errors). Suppose 10 students with 10 balances are to determine the mass of the same dime. The 10 measurements will probably vary slightly for various reasons. The balances might be calibrated slightly differently, and there might be differences in how each student reads the mass from the balance. Remember: *Uncertainties always exist in measured quantities.*

Precision and Accuracy

The terms *precision* and *accuracy* are often used in discussing the uncertainties of measured values. **Precision** is a measure of how closely individual measurements agree with one another. **Accuracy** refers to how closely individual measurements agree with the correct, or "true," value. The dart analogy in **Figure 1.22** illustrates the difference between these two concepts.

In the laboratory, we often perform several "trials" of an experiment and average the results. The precision of the measurements is often expressed in terms of the *standard deviation* (Appendix A.5), which reflects how much the individual measurements differ from the average. We gain confidence in our measurements if we obtain nearly the same value each time—that is, when the standard deviation is small. Figure 1.22 reminds us, however, that precise measurements can be inaccurate. For example, in the laboratory portion of your course, you will likely use a high-precision balance, such as the one shown in **Figure 1.23**, to measure quantities of substances. Such balances can typically measure masses to 0.1 mg accuracy; the glass enclosure that surrounds the weighing pan keeps the measurement from being affected by any motion of the air in the room. However, if a very sensitive balance is poorly calibrated, the masses we measure will be consistently either high or low. They will be inaccurate even if they are precise.

Significant Figures

Suppose you determine the mass of a dime on a balance capable of measuring to the nearest 0.0001 g. You could report the mass as 2.2405 ± 0.0001 g. The ± notation (read "plus or minus") expresses the magnitude of the uncertainty of your measurement. In much scientific work, we drop the ± notation with the understanding that *there is always some uncertainty in the last digit reported for any measured quantity.*

Figure 1.24 shows a thermometer with its liquid column between two scale marks. We can read the certain digits from the scale and estimate the uncertain one. Seeing that the liquid is between the 25 °C and 30 °C marks, we estimate the temperature to be 27 °C, being uncertain of the second digit of our measurement. By *uncertain* we mean that the temperature is reliably 27 °C and not 28 °C or 26 °C, but we can't say that it is *exactly* 27 °C.

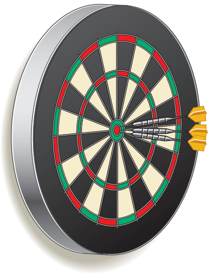
Learning Objectives

When you finish Section 1.6, you should be able to:

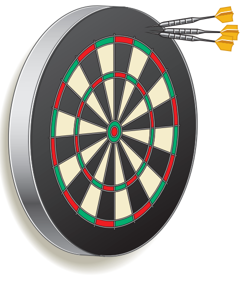
- Distinguish between *exact* and *inexact* numbers in scientific calculations.
- Explain the difference between the *precision* and *accuracy* of a measurement.
- Demonstrate the use of significant figures, exponential notation, and SI units in calculations.

Go Figure

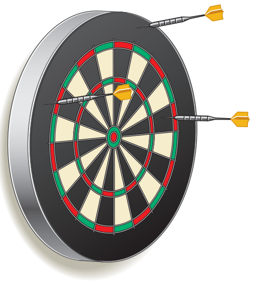
How would the darts be positioned on the target for the case of "good accuracy, poor precision"?



Good accuracy
Good precision

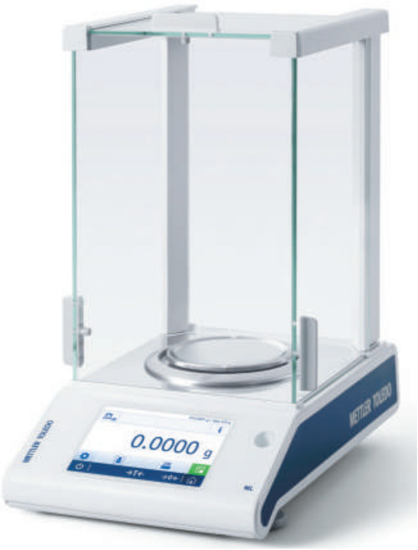


Poor accuracy
Good precision



Poor accuracy
Poor precision

▲ **Figure 1.22** **Precision and accuracy.**



▲ **Figure 1.23** **High-precision digital balance used in a chemistry laboratory.** Digital balances provide more precision than those that involve pans and weights. This one shows masses to 0.0001 g. The glass housing around the balance pan keeps air currents from affecting the measurement.

All digits of a measured quantity, including the uncertain one, are called **significant figures**. A measured mass reported as 2.2 g has two significant figures, whereas one reported as 2.2405 g has five significant figures. The greater the number of significant figures, the greater the precision implied for the measurement.

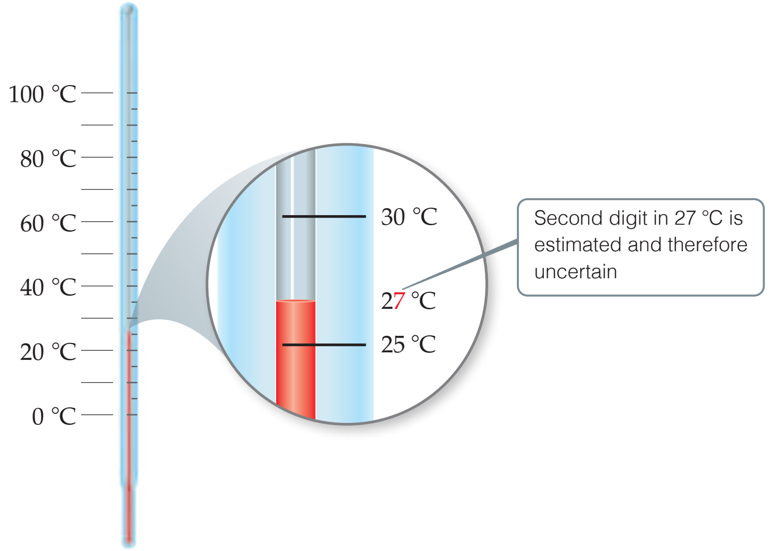
To determine the number of significant figures in a reported measurement, read the number from left to right, counting the digits starting with the first digit that is not zero. *In any measurement that is properly reported, all nonzero digits are significant.* Because zeros can be used either as part of the measured value or merely to locate the decimal point, they may or may not be significant:

- Zeros *between* nonzero digits are always significant—1005 kg (four significant figures); 7.03 cm (three significant figures).
- Zeros *at the beginning* of a number are never significant; they merely indicate the position of the decimal point—0.02 g (one significant figure); 0.0026 cm (two significant figures).
- Zeros *at the end* of a number are significant if the number contains a decimal point—0.0200 g (three significant figures); 3.0 cm (two significant figures).

A question arises when a number ends with zeros but contains no decimal point. In such cases, it is normally assumed that the zeros are *not* significant. Exponential notation (Appendix A.1) can be used to indicate whether end zeros are significant. For example, a mass of 10,300 g can be written to show three, four, or five significant figures, depending on how the measurement is obtained:

1.03×10^4 g	(three significant figures)
1.030×10^4 g	(four significant figures)
1.0300×10^4 g	(five significant figures)

In these numbers, all the zeros to the right of the decimal point are significant (rules 1 and 3). (The exponential term 10^4 does not add to the number of significant figures.) Notice the advantage of using exponential notation: Reporting a mass as 10,300 g suggests that only three digits are significant even if the measurement has greater precision than that.



Second digit in 27 °C is estimated and therefore uncertain

▲ **Figure 1.24** **Uncertainty and significant figures in a measurement.**

Sample Exercise 1.6

Assigning Appropriate Significant Figures

The state of Colorado is listed in a road atlas as having a population of 5,546,574 and an area of 104,091 square miles. Do the numbers of significant figures in these two quantities seem reasonable? If not, what seems to be wrong with them?

SOLUTION

The population of Colorado must vary from day to day as people move in or out, are born, or die. Thus, the reported number suggests a much higher degree of *accuracy* than is possible. Moreover, it would not be feasible to actually count every individual resident in the state at any given time. Thus, the reported number suggests far greater *precision* than is possible. A reported number of 5,500,000 would better reflect the actual state of knowledge.

The area of Colorado does not normally vary from time to time, so the question here is whether the accuracy of the measurements is good to six significant figures. It would be possible to achieve such accuracy using satellite technology, provided the legal boundaries are known with sufficient accuracy.

Practice Exercise

A 3-lb bag of onions at the grocery store is found to have 14 onions in it. Are the two numbers in this statement—3 and 14—exact or inexact numbers?

Sample Exercise 1.7

Determining the Number of Significant Figures in a Measurement

How many significant figures are in each of the following numbers (assume that each number is a measured quantity)? (**a**) 5000, (**b**) 6.023×10^{23}, (**c**) 4.003.

SOLUTION

(**a**) One; we assume that the zeros are not significant when there is no decimal point shown. If the number has more significant figures, a decimal point should be employed or the number should be written in exponential notation. Thus, 5000. has four significant figures, and 5.00×10^3 has three, whereas 5000, with no decimal point, has only one. (**b**) Four; the exponential term does not add to the number of significant figures. (**c**) Four; the zeros are significant figures.

Practice Exercise

How many significant figures are in each of the following measurements? (**a**) 3.549 g, (**b**) 2.3×10^4 cm, (**c**) 0.00134 m^3.

Significant Figures in Calculations

Apply the following rule when carrying measured quantities through calculations:

> *The least certain measurement limits the certainty of the calculated quantity and thereby determines the number of significant figures in the final answer.*

The final answer should be reported with only one uncertain digit. To keep track of significant figures in calculations, we make frequent use of two rules—one for addition and subtraction, and another for multiplication and division.

1. *For addition and subtraction,* the result has the same number of decimal places as the measurement with the *fewest decimal places.* When the result contains more than the correct number of significant figures, it must be rounded to the correct number. Consider the following example in which the uncertain digits appear in color:

20.42	⟵ two decimal places
1.322	⟵ three decimal places
83.1	⟵ one decimal places
104.842	⟵ round off to one decimal place (104.8)

This number limits the number of the significant figures in the result

We report the result as 104.8 because 83.1 has only one digit past the decimal point.

Note that whole numbers without decimal points have *zero* decimal places. We look at the first nonzero digit going from right to left to determine what is significant. Thus:

$54 + 137 = 191$ (the "ones digit" is significant in both numbers that are being added)

$120 + 18 = 138$, which must be rounded to 140 (the last significant figure in 120 is in the "tens digit")

2. *For multiplication and division*, the result contains the same number of significant figures as the measurement with the *fewest significant figures*. When the result contains more than the correct number of significant figures, it must be rounded. For example, the area of a rectangle whose measured edge lengths are 6.221 and 5.2 cm, is the product of the lengths of the two sides. The area should be reported with two significant figures, 32 cm^2, even though a calculator shows the product to have more digits:

$$\text{Area} = (6.221\ \text{cm})(5.2\ \text{cm}) = 32.3492\ \text{cm}^2 \Rightarrow \text{round off to } 32\ \text{cm}^2$$

because 5.2 has two significant figures.

In determining the final answer for a calculated quantity, *exact numbers* are assumed to have an infinite number of significant figures. Thus, when we say, "There are 12 inches in 1 foot," the number 12 is exact, and we need not worry about the number of significant figures in it.

When *rounding numbers*, look at the leftmost digit to be removed:

- If the leftmost digit removed is less than 5, the preceding number is left unchanged. Thus, rounding 7.248 to two significant figures gives 7.2.
- If the leftmost digit removed is 5 or greater, the preceding number is increased by 1. Rounding 4.735 to three significant figures gives 4.74, and rounding 2.376 to two significant figures gives 2.4.*

Sample Exercise 1.8

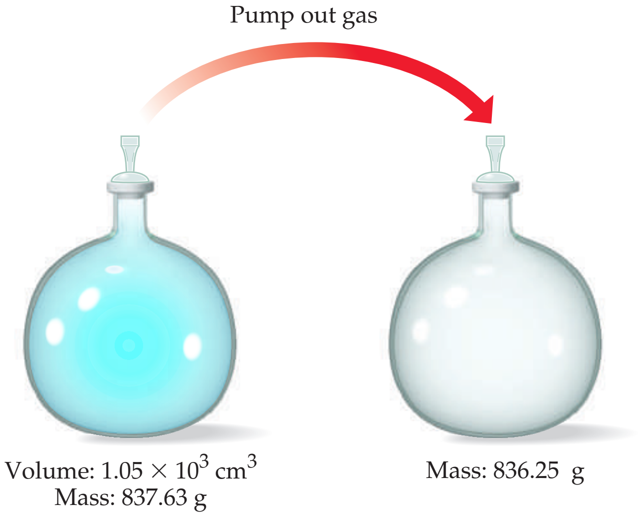
Determining the Number of Significant Figures in a Calculated Quantity

A vessel containing a gas at 25 °C is weighed, emptied, and then reweighed as depicted in **Figure 1.25**. From the data provided, calculate the density of the gas at 25 °C.

SOLUTION

To calculate the density, we must know both the mass and the volume of the gas. The mass of the gas is just the difference in the masses of the full and empty container:

$$\begin{array}{r} 837.63\ \text{g} \\ -836.25\ \text{g} \\ \hline 1.38\ \text{g} \end{array}$$



▲ **Figure 1.25 Uncertainty and significant figures in a measurement.**

In subtracting numbers, we determine the number of significant figures in our result by counting decimal places in each quantity. In this case, each quantity has two decimal places. Thus, the mass of the gas, 1.38 g, has two decimal places. Notice that although each of the individual weights has five significant figures, the difference in the weights has only three significant figures.

Using the volume given in the question, $1.05 \times 10^3\ \text{cm}^3$, and the definition of density, we have

$$\text{Density} = \frac{\text{mass}}{\text{volume}} = \frac{1.38\ \text{g}}{1.05 \times 10^3\ \text{cm}^3}$$
$$= 1.31 \times 10^{-3}\ \text{g/cm}^3 = 0.00131\ \text{g/cm}^3$$

In dividing numbers, we determine the number of significant figures our result should contain by counting the number of significant figures in each quantity. There are three significant figures in our answer, corresponding to the number of significant figures in the two numbers that form the ratio. In this example, then, following the rules for determining significant figures gives an answer containing only three significant figures, even though the measured masses contain five significant figures.

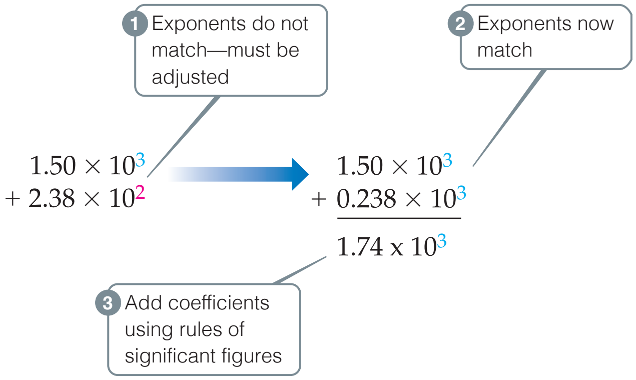
▶ Practice Exercise

If the mass of the container in the sample exercise (Figure 1.25) were measured to three decimal places before and after pumping out the gas, could the density of the gas then be calculated to four significant figures?

---

*Your instructor may want you to use a slight variation on the rule when the leftmost digit to be removed is exactly 5, with no following digits or only zeros following. One common practice is to round up to the next higher number if that number will be even and down to the next lower number otherwise. Thus, 4.7350 would be rounded to 4.74, and 4.7450 would also be rounded to 4.74.

To complete our discussion of significant figures, let's look a little more closely at how we handle them when numbers are expressed in exponential notation. When addition and subtraction are involved, we must make sure that each number has the same exponent. For example, consider adding 1.50×10^3 and 2.38×10^2. Before we do so, we will need to express the second number with the same exponent as the first number:



① Exponents do not match—must be adjusted

② Exponents now match

③ Add coefficients using rules of significant figures

Notice that when we add the numbers, the 8 in the second number is no longer significant because the first number has only two digits past the decimal. We round the final result to the correct number of significant figures past the decimal. You should demonstrate to yourself that we would have gotten the same answer if we had adjusted the exponent of the first number rather than the second.

Multiplying and dividing numbers in exponential notation follow the same rules for multiplication and division that we described before. The number of significant figures is equal to that in the number with the smaller number of significant figures:

$$(6.743 \times 10^{-5}) \times (5.26 \times 10^2) = (6.743 \times 5.26) \times (10^{-5} \times 10^2) = 35.5 \times 10^{-3} = 3.55 \times 10^{-2}$$

Notice that the final answer has three significant figures, the same as 5.26×10^2. Moreover, we have adjusted the exponent in the final answer to get a number between 1 and 10, as is usual for exponential notation.

Finally, you will likely face situations in which you have to do more than one calculation to get the final answer. In general, *when a calculation involves two or more steps and you write answers for intermediate steps, retain at least one nonsignificant digit for the intermediate answers.* This procedure ensures that small errors from rounding at each step do not combine to affect the final result. When using a calculator, you may enter the numbers one after another, rounding only the final answer. Accumulated rounding-off errors may account for small differences among results you obtain and answers given in the text for numerical problems.

Sample Exercise 1.9

Significant Figures and Exponential Notation

Calculate the result of the following to the correct number of significant figures:

$$(9.60 \times 10^4 + 8.3 \times 10^3)/(5.2687 \times 10^2)$$

SOLUTION

To get the answer, we need to carry out two successive calculations. First, we sum the numbers in the numerator, then divide by the number in the denominator. To add the numbers in the numerator, we adjust the second number so that it has the same exponent as the first:

$$(9.60 \times 10^4) + (8.3 \times 10^3) = \underbrace{(9.60 \times 10^4) + (0.83 \times 10^4)}_{\text{match exponents}} = \underbrace{10.43 \times 10^4}_{\text{add}} = \underbrace{1.043 \times 10^5}_{\text{adjust exponent for exponential notation}}$$

Notice that we first rewrite 8.3×10^3 as 0.83×10^4 in order to have the same exponent as the 9.60×10^4. We then add the numbers. Because both have two digits after the decimal, the result has

Continued

two digits past the decimal as well. We then rewrite the result in standard exponential notation—namely, a number between 1 and 10 multiplied by an exponent.

We now divide the sum in the numerator by the number in the denominator:

$$(1.043 \times 10^5)/(5.2687 \times 10^2) = 0.1980 \times 10^3 = 1.980 \times 10^2$$

The numerator of this quotient has four significant figures, and the denominator has five. We therefore express the answer to four significant figures, the smaller number.

Practice Exercise

Determine the value of the following expression to the correct number of significant figures:

$$146.3/(4.3 \times 10^4 + 6.75 \times 10^5)$$

Self-Assessment Exercises

SAE 1.19 Consider the following three quantities:

- (**i**) the dimensions of your lecture hall
- (**ii**) the mass of a piece of paper
- (**iii**) the number of nanometers in a meter

Which of these quantities is or are *inexact*? (**a**) Only one of them is inexact (**b**) i and ii (**c**) i and iii (**d**) ii and iii (**e**) All three are inexact.

SAE 1.20 A sensitive balance is miscalibrated by using an incorrect standard weight. You make four trial weights of a sample using this balance and get the following values: 1.5201 g, 1.5203 g, 1.5199 g, and 1.5202 g. Which of the following describes the precision and accuracy of your measurements? (**a**) good precision, good accuracy (**b**) poor precision, poor accuracy (**c**) poor precision, good accuracy (**d**) good precision, poor accuracy.

SAE 1.21 A volumetric flask has a reported volume of 0.00250 L. How many significant figures are there in this measurement? (**a**) 2 (**b**) 3 (**c**) 4 (**d**) 5 (**e**) 6

SAE 1.22 A hiker has a timer to check her speed during a hike. At a time of 115 min into the hike, she passes a distance post marked 9.4 km. Later, at 275 min into her hike, she passes a post marked 22.9 km. What is her average speed in km/hr between these two posts given to the correct number of significant figures? (**a**) 5 km/h (**b**) 5.1 km/h (**c**) 5.06 km/h (**d**) 5.063 km/h (**e**) 5.0625 km/h

STRATEGIES FOR SUCCESS **Estimating Answers**

Calculators are wonderful devices; they enable you to get to the wrong answer very quickly! Fortunately, you can take certain steps to avoid putting that wrong answer into your homework set or your exam paper. First, keep track of the units in a calculation and use the correct conversion factors. Second, do a quick mental check to be sure that your answer is reasonable by making a "ballpark" estimate or a "back-of-the-envelope" calculation.

A ballpark estimate involves making a rough calculation using numbers that are rounded off in such a way that the arithmetic can be done without a calculator. Even though this approach does not give an exact answer, it gives one that is roughly the correct size. By using dimensional analysis and by estimating answers, you can readily check the reasonableness of your calculations.

You can get better at making estimates by practicing in everyday life. How far is it from your dorm room to the chemistry lecture hall? How much do your parents pay for gasoline per year? How many bikes are there on campus? If you respond "I have no idea" to these questions, you're giving up too easily. Try estimating familiar quantities and you'll get better at making estimates in science and in other aspects of your life where a misjudgment can be costly.

1.7 | Dimensional Analysis

Learning Objectives

When you finish Section 1.7, you should be able to:

- Use and, as needed, combine conversion factors in order to arrive at the desired units for an answer.
- Perform calculations in which we raise a known conversion factor by a power.

Because measured quantities have units associated with them, it is important to keep track of units as well as numerical values when using the quantities in calculations. In this section, we show you how to use the units as a guide to solving problems correctly by applying a technique called *dimensional analysis*.

In **dimensional analysis**, units are multiplied together or divided into each other along with the numerical values that accompany them. By canceling equivalent units, we can keep track of both the nature and quantity of what has been calculated. Using dimensional analysis helps ensure that solutions to problems yield the proper units. Moreover, it provides a systematic way of solving many numerical problems and of checking solutions for possible errors.

Conversion Factors

The key to successful dimensional analysis is the correct use of *conversion factors* to change one unit into another. A **conversion factor** is a fraction whose numerator and denominator are the same quantity expressed in different units. For example, 2.54 cm and 1 in. are, by definition, the same length: 2.54 cm = 1 in. This relationship allows us to write two conversion factors:

$$\frac{2.54\ \text{cm}}{1\ \text{in.}} \quad \text{and} \quad \frac{1\ \text{in.}}{2.54\ \text{cm}}$$

We use the first factor to convert inches to centimeters. For example, the length in centimeters of an object that is 8.50 in. long is

Desired unit

$$\text{Number of centimeters} = (8.50\ \cancel{\text{in.}})\frac{2.54\ \text{cm}}{1\ \cancel{\text{in.}}} = 21.6\ \text{cm}$$

Given unit

The unit of inches in the denominator of the conversion factor (1 *inch*) cancels the unit of inches in the given data (8.50 *inches*), so that the centimeters unit in the numerator of the conversion factor becomes the unit of the final answer. Because the numerator and denominator of a conversion factor are equal, multiplying any quantity by a conversion factor is equivalent to multiplying by the number 1 and so does not change the intrinsic value of the quantity. The length 8.50 in. is the same as the length 21.6 cm.

In general, we begin any conversion by examining the units of the given data and the units we desire. We then ask ourselves what conversion factors we have available to take us from the units of the given quantity to those of the desired one. When we multiply a quantity by a conversion factor, the units multiply and divide as follows:

$$\cancel{\text{Given unit}} \times \frac{\text{desired unit}}{\cancel{\text{given unit}}} = \text{desired unit}$$

If the desired units are not obtained in a calculation, an error must have been made somewhere. Careful inspection of units often reveals the source of the error.

Sample Exercise 1.10

Converting Units

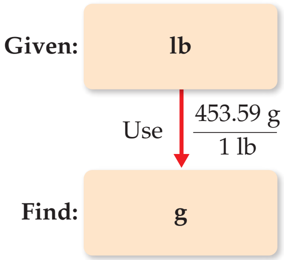
If a weightlifting barbell has a mass of 125 lb, what is its mass in grams? (Note: 1 lb = 453.59 g)

SOLUTION

Because we are given the mass in pounds and want to express the mass in grams, we use a relationship between these units of mass. The conversion factor is given: 1 lb = 453.59 g. To cancel pounds and leave grams, we write the conversion factor with grams in the numerator and pounds in the denominator:

$$\text{Mass in grams} = (125\ \cancel{\text{lb}})\left(\frac{453.59\ \text{g}}{1\ \cancel{\text{lb}}}\right) = 5.67 \times 10^4\ \text{g}$$

The answer is given to three significant figures, which is the number of significant figures in 125 lb. The process we have used is diagrammed in the drawing shown.



Practice Exercise

By using a conversion factor from the back inside cover, determine the length in kilometers of a 500.0-mi automobile race.

Using Two or More Conversion Factors

It is often necessary to use several conversion factors in solving a problem. As an example, let's convert the length of an 8.00-m rod to inches. The table on the back inside cover does not give the relationship between meters and inches. It *does*, however, give the relationship between centimeters and inches (1 in. = 2.54 cm). From our knowledge of SI prefixes, we know that 1 cm $=$ 10^{-2} m. Thus, we can convert step by step, first from meters to centimeters and then from centimeters to inches:

Given: **Find:**

$$\textbf{m} \xrightarrow[\dfrac{1\text{ cm}}{10^{-2}\text{ m}}]{\text{Use}} \textbf{cm} \xrightarrow[\dfrac{1\text{ in.}}{2.54\text{ cm}}]{\text{Use}} \textbf{in.}$$

Combining the given quantity (8.00 m) and the two conversion factors, we have

$$\text{Number of inches} = (8.00\ \cancel{\text{m}})\left(\frac{1\ \cancel{\text{cm}}}{10^{-2}\ \cancel{\text{m}}}\right)\left(\frac{1\text{ in.}}{2.54\ \cancel{\text{cm}}}\right) = 315\text{ in.}$$

The first conversion factor is used to cancel meters and convert the length to centimeters. Thus, meters are written in the denominator and centimeters in the numerator. The second conversion factor is used to cancel centimeters and convert the length to inches, so it has centimeters in the denominator and inches, the desired unit, in the numerator. The final answer is given to three significant figures, which is the number of significant figures in 8.00 m. Both of the conversion factors are exact numbers, so we do not need to consider those in determining the number of significant figures in the answer.

Note that you could also have used 100 cm $=$ 1 m as a conversion factor in the second parentheses. As long as you keep track of your given units and cancel them properly to obtain the desired units, you will be successful in your calculations.

Sample Exercise 1.11

Converting Units Using Two or More Conversion Factors

The average speed of a nitrogen molecule in air at 25 °C is 515 m/s. Convert this speed to miles per hour.

SOLUTION

To go from the given units, m/s, to the desired units, mi/h, we must convert meters to miles and seconds to hours. From our knowledge of SI prefixes we know that 1 km $=$ 10^3 m. From the relationships given on the back inside cover of the book, we find that 1 mi $=$ 1.6093 km. Thus, we can convert m to km and then convert km to mi. From our knowledge of time, we know that 60 s $=$ 1 min and 60 min $=$ 1 h. Thus, we can convert s to min and then convert min to h. The overall process is

Given: **Find:**

$$\textbf{m/s} \xrightarrow[\dfrac{1\text{ km}}{10^{3}\text{ m}}]{\text{Use}} \textbf{km/s} \xrightarrow[\dfrac{1\text{ mi}}{1.6093\text{ km}}]{\text{Use}} \textbf{mi/s} \xrightarrow[\dfrac{60\text{ s}}{1\text{ min}}]{\text{Use}} \textbf{mi/min} \xrightarrow[\dfrac{60\text{ min}}{1\text{ h}}]{\text{Use}} \textbf{mi/h}$$

Applying first the conversions for distance and then those for time, we can set up one long equation in which unwanted units are canceled:

$$\text{Speed in mi/h} = \left(515\,\frac{\cancel{\text{m}}}{\cancel{\text{s}}}\right)\left(\frac{1\ \cancel{\text{km}}}{10^3\ \cancel{\text{m}}}\right)\left(\frac{1\text{ mi}}{1.6093\ \cancel{\text{km}}}\right)\left(\frac{60\ \cancel{\text{s}}}{1\ \cancel{\text{min}}}\right)\left(\frac{60\ \cancel{\text{min}}}{1\text{ h}}\right)$$

$$= 1.15 \times 10^3\text{ mi/h}$$

Our answer has the desired units. We can check our calculation using the estimating procedure described in the “Strategies in Success” box. The given speed is about 500 m/s. Dividing by 1000 converts m to km, giving 0.5 km/s. Because 1 mi is about 1.6 km, this speed corresponds to $0.5/1.6 = 0.3$ mi/s. Multiplying by 60 gives about $0.3 \times 60 = 20$ mi/min. Multiplying again by 60 gives $20 \times 60 = 1200$ mi/h. The approximate solution (about 1200 mi/h) and the detailed solution (1150 mi/h) are satisfyingly close. The answer to the detailed solution has three significant figures, corresponding to the number of significant figures in the given speed in m/s.

Practice Exercise

A car travels 32 mi per gallon of gasoline. What is the mileage in kilometers per liter?

Calculations in Which a Conversion Factor Is Raised to a Power

The conversion factors previously noted convert from one unit of a given measure to another unit of the same measure, such as from length to length. We also have conversion factors that convert from one measure to a different one. The density of a substance, for example, can be treated as a conversion factor between mass and volume. Suppose we want to know the mass in grams of 2 cubic inches ($2.00\ \text{in.}^3$) of gold, which has a density of $19.3\ \text{g/cm}^3$. The density gives us the conversion factors:

$$\frac{19.3\ \text{g}}{1\ \text{cm}^3} \quad \text{and} \quad \frac{1\ \text{cm}^3}{19.3\ \text{g}}$$

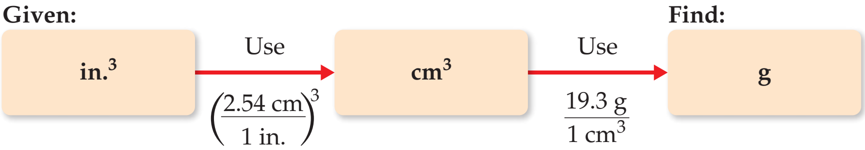
Because we want a mass in grams, we use the first factor, which has mass in grams in the numerator. To use this factor, however, we must first convert cubic inches to cubic centimeters. The relationship between in.^3 and cm^3 is not given on the back inside cover, but the relationship between inches and centimeters is given: 1 in. = 2.54 cm (exactly). By cubing this conversion factor, we obtain the desired conversion:

$$\left(\frac{2.54\ \text{cm}}{1\ \text{in.}}\right)^3 = \frac{(2.54)^3\ \text{cm}^3}{(1)^3\ \text{in.}^3} = \frac{16.39\ \text{cm}^3}{1\ \text{in.}^3}$$

Notice that both the numbers and the units are cubed. Also, because 2.54 is an exact number, we can retain as many digits of $(2.54)^3$ as we need. We have used four, one more than the number of digits in the density ($19.3\ \text{g/cm}^3$). Applying our conversion factors, we can now solve the problem:

$$\text{Mass in grams} = (2.00\ \cancel{\text{in.}^3})\left(\frac{16.39\ \cancel{\text{cm}^3}}{1\ \cancel{\text{in.}^3}}\right)\left(\frac{19.3\ \text{g}}{1\ \cancel{\text{cm}^3}}\right) = 633\ \text{g}$$

The procedure is diagrammed here. The final answer is reported to three significant figures, the same number of significant figures as in $2.00\ \text{in.}^3$ and $19.3\ \text{g/cm}^3$.



Given:
in.^{3}
Use
$\left(\frac{2.54\ \text{cm}}{1\ \text{in.}}\right)^3$
cm^3
Use
$\frac{19.3\ \text{g}}{1\ \text{cm}^3}$
Find:
g

Sample Exercise 1.12
Converting Volume Units

Earth's oceans contain approximately $1.36 \times 10^9\ \text{km}^3$ of water. Calculate the volume in liters.

SOLUTION

From the back inside cover, we find $1\ \text{L} = 10^{-3}\ \text{m}^3$, but there is no relationship listed involving km^3. From our knowledge of SI prefixes, however, we know that $1\ \text{km} = 10^3\ \text{m}$, so we can use this relationship between lengths to write the desired conversion factor between volumes:

$$\left(\frac{10^3\ \text{m}}{1\ \text{km}}\right)^3 = \frac{10^9\ \text{m}^3}{1\ \text{km}^3}$$

Thus, converting from km^3 to m^3 to L, we have

$$\text{Volume in liters} = (1.36 \times 10^9\ \cancel{\text{km}^3})\left(\frac{10^9\ \cancel{\text{m}^3}}{1\ \cancel{\text{km}^3}}\right)\left(\frac{1\ \text{L}}{10^{-3}\ \cancel{\text{m}^3}}\right)$$
$$= 1.36 \times 10^{21}\ \text{L}$$

▶ **Practice Exercise**

The surface area of Earth is $510 \times 10^6\ \text{km}^2$, and 71% of this is ocean. Using the data from the sample exercise, calculate the average depth of the world's oceans in feet.

Sample Exercise 1.13
Conversions Involving Density

What is the mass in grams of 2.00 gal of water? The density of water is 1.00 g/mL.

SOLUTION

Before we begin solving this exercise, we note the following:

(**1**) We are given 2.00 gal of water (the known, or given, quantity) and asked to calculate its mass in grams (the unknown).

(**2**) We have the following conversion factors either given, commonly known, or available on the back inside cover of the text:

$$\frac{1.00\ \text{g water}}{1\ \text{mL water}} \quad \frac{1\ \text{L}}{1000\ \text{mL}} \quad \frac{1\ \text{L}}{1.057\ \text{qt}} \quad \frac{1\ \text{gal}}{4\ \text{qt}}$$

The first of these conversion factors must be used as written (with grams in the numerator) to give the desired result, whereas the last conversion factor must be inverted in order to cancel gallons:

$$\text{Mass in grams} = (2.00\ \cancel{\text{gal}})\left(\frac{4\ \cancel{\text{qt}}}{1\ \cancel{\text{gal}}}\right)\left(\frac{1\ \cancel{\text{L}}}{1.057\ \cancel{\text{qt}}}\right)\left(\frac{1000\ \cancel{\text{mL}}}{1\ \cancel{\text{L}}}\right)\left(\frac{1.00\ \text{g}}{1\ \cancel{\text{mL}}}\right)$$

$$= 7.57 \times 10^3\ \text{g water}$$

The unit of our final answer is appropriate, and we have taken care of our significant figures. We can further check our calculation by estimating. We can round 1.057 off to 1. Then focusing on the numbers that do not equal 1 gives 8 × 1000 = 8000 g, in agreement with the detailed calculation.

You should also use common sense to assess the reasonableness of your answer. In this case we know that most people can lift two gallons of milk, although it would be tiring to carry them around all day. Milk is mostly water and will have a density not too different from that of water. Therefore, we might estimate that a gallon of water has mass that is more than 5 lb but less than 50 lb. The mass we have calculated, 7.57 kg × 2.2 lb/kg = 16.7 lb, is thus reasonable.

▶ Practice Exercise

The density of the organic compound *benzene* is 0.879 g/mL. Calculate the mass in grams of 1.00 qt of benzene.

Self-Assessment Exercises

SAE 1.23 The mass of Earth is estimated to be 5.97×10^{27} g. What is the mass of Earth in lb to three significant figures? (Note: 1 kg = 2.2046 lb.)

(a) 1.32×10^{25} lb
(b) 2.71×10^{24} lb
(c) 1.32×10^{28} lb
(d) 2.71×10^{27} lb
(e) 5.97×10^{24} lb

SAE 1.24 A new hybrid vehicle achieves highway gas distance that is listed as 25 km/L. What is the highway gas distance in miles per gallon? (Note: 1 mi = 1.609 km and 1 gal = 3.785 L.) **(a)** 4.1 mi/gal **(b)** 40 mi/gal **(c)** 59 mi/gal **(d)** 95 mi/gal **(e)** 150 mi/gal

SAE 1.25 In 2018, the population density in Singapore was 21,400 residents per square mile. What is the population density of Singapore in residents per square kilometer? (Note: 1 mi = 1.609 km.)

(a) 8.27×10^3 residents/km^2
(b) 1.33×10^4 residents/km^2
(c) 2.34×10^4 residents/km^2
(d) 3.44×10^4 residents/km^2
(e) 5.54×10^4 residents/km^2

STRATEGIES FOR SUCCESS The Importance of Practice—and How to Use the Book

If you have ever played a musical instrument or participated in athletics, you know that the keys to success are practice and discipline. You cannot learn to play a piano merely by listening to music, and you cannot learn how to play basketball merely by watching games on television. Likewise, you cannot learn chemistry by merely watching your instructor give lectures. Simply reading this book, listening to lectures, or reviewing notes will not usually be sufficient when exam time comes around. Your task is to master chemical concepts to a degree that you can put them to use in solving problems and answering questions. Solving problems correctly takes practice—actually, a fair amount of it. You will do well in your chemistry course if you embrace the idea that you need to master the materials presented and then learn how to apply them in solving problems. Even if you're a brilliant student, this will take time; it's what being a student is all about. Almost no one fully absorbs new material on a first reading, especially when new concepts are being presented. You are sure to master the content of the chapters more fully by reading them through at least twice, even more for passages that present you with difficulties in understanding.

Throughout the book, we have provided sample exercises in which the solutions are shown in detail. For practice exercises, we supply only the answer, at the back of the book. It is important that you use these exercises to test yourself.

Each chapter of the book is broken into a number of sections, each of which can be treated as a module for learning. At the beginning of each section, we present a bulleted list of learning goals for you, introduced with the suggestion "When you finish this section, you should be able to." These will serve as a checklist to keep you on track in your learning of the material in the section. At the end of each section we have provided a brief set of multiple-choice Self-Assessment Exercises (SAEs). The SAEs are multiple-choice questions that link directly to the learning goals for the section. Research has shown that interleaving passive learning (for example, reading) with active problem solving is an effective approach to mastering concepts and skills, so you will find it helpful to complete the SAEs for a given section before moving on to the next section.

At the end of each chapter, we also provide you with a set of Exam Prep questions, which will help you test yourself on your understanding of the chapter as a whole. You will find it helpful to attempt these Exam Prep questions before moving forward to the next chapter.

The practice exercises in this text and the homework assignments given by your instructor provide the minimal practice that you will need to succeed in your chemistry course. Only by working all the assigned problems will you face the full range of difficulty and coverage that your instructor expects you to master for exams. There is no substitute for a determined and perhaps lengthy effort to work problems on your own. If you are stuck on a problem, however, ask for help from your instructor, a teaching assistant, a tutor, or a fellow student. Spending an inordinate amount of time on a single exercise is rarely effective unless you know that it is particularly challenging and is expected to require extensive thought and effort.

Finally, if you haven't done so as yet, we suggest you read the TO THE STUDENT material in the Preface of the book. There we provide you with guidance on how text features such as "What's Ahead," Key Terms, Learning Outcomes, and Key Equations will help you remember what you have learned. You will also find out more about other key features in the book, such as the Visualizing Concepts exercises at the end of each chapter as well as the various other categories within the end-of-chapter exercises.

We want your journey in chemistry to be a productive and even an enjoyable one! We hope you find the tools we provide to assist you in your learning of chemistry to be helpful and enriching. It is a wonderful, if at times daunting, journey, and we want you to be successful in it.

Chapter Summary and Key Terms

THE STUDY OF CHEMISTRY (SECTION 1.1) **Chemistry** is the study of the composition, structure, properties, and changes of **matter**. The composition of matter relates to the kinds of **elements** it contains. The structure of matter relates to the ways the **atoms** of these elements are arranged. A **property** is any characteristic that gives a sample of matter its unique identity. A **molecule** is an entity composed of two or more atoms, with the atoms attached to one another in a specific way.

CLASSIFICATIONS OF MATTER (SECTION 1.2) Matter exists in three physical states—**gas**, **liquid**, and **solid**—which are known as the **states of matter**. There are two kinds of **pure substances**: **elements** and **compounds**. Each element has a single kind of atom and is represented by a chemical symbol consisting of one or two letters, with the first letter capitalized. Compounds are composed of two or more elements joined chemically. The **law of constant composition**, also called the **law of definite proportions**, states that the elemental composition of a pure compound is always the same. Most matter consists of a mixture of substances. **Mixtures** have variable compositions and can be either homogeneous or heterogeneous; homogeneous mixtures are called **solutions**.

PROPERTIES OF MATTER (SECTION 1.3) Each substance has a unique set of **physical properties** and **chemical properties** that can be used to identify it. During a **physical change**, matter does not change its composition. **Changes of state** are physical changes. In a **chemical change (chemical reaction)**, a substance is transformed into a chemically different substance. **Intensive properties** are independent of the amount of matter examined and are used to identify substances. **Extensive properties** relate to the amount of substance present. Differences in physical and chemical properties are used to separate substances. Three common separation techniques are **filtration**, **distillation**, and **chromatography**.

THE NATURE OF ENERGY (SECTION 1.4) **Energy** is defined as the capacity to do work or transfer heat. **Work** is the energy transferred when a force exerted on an object causes a displacement of that object. **Heat** is the energy used to cause the temperature of an object to increase. An object can possess energy in two forms: **kinetic energy**, which is the energy associated with the motion of an object, and **potential energy**, which is the energy that an object possesses by virtue of its position relative to other objects. Important forms of potential energy include gravitational energy and electrostatic energy.

UNITS OF MEASUREMENT (SECTION 1.5) Measurements in chemistry are made using the **metric system**. Special emphasis is placed on **SI units**, which are based on the meter (m), the kilogram (kg), and the second (s) as the basic units of length, **mass**, and time, respectively. SI units use prefixes to indicate fractions or multiples of base units. The SI **temperature** scale is the **Kelvin scale**, although the **Celsius scale** is frequently used as well. **Absolute zero** is the lowest temperature attainable. It has the value 0 K. A **derived unit** is obtained by multiplication or division of SI base units. Derived units are needed for defined quantities such as speed or volume. **Density** is an important derived unit that equals mass divided by volume. The SI unit of energy is the **joule** (J): $1\ \text{J} = 1\ \text{kg-m}^2/\text{s}^2$. The **calorie** (cal) is a commonly used non-SI unit of energy: $1\ \text{cal} = 4.18\ \text{J}$.

UNCERTAINTY IN MEASUREMENT AND SIGNIFICANT FIGURES (SECTION 1.6) All measured quantities are inexact to some extent. The **precision** of a measurement indicates how closely different measurements of a quantity agree with one another. The **accuracy** of a measurement indicates how well a measurement agrees with the accepted or “true” value. The **significant figures** in a measured quantity include one estimated digit, the last digit of the measurement. The significant figures indicate the extent of the uncertainty of the measurement. Certain rules must be followed so that a calculation involving measured quantities is reported with the appropriate number of significant figures.

DIMENSIONAL ANALYSIS (SECTION 1.7) In the **dimensional analysis** approach to problem solving, we keep track of units as we carry measurements through calculations. The units are multiplied together, divided into each other, or canceled like algebraic quantities. Obtaining the proper units for the final result is an important means of checking the method of calculation. When converting units and when carrying out several other types of problems, **conversion factors** are used. These factors are ratios constructed from valid relations between equivalent quantities.

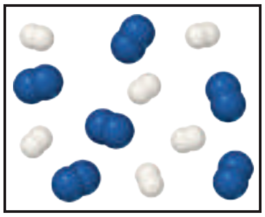
Key Equations

• $w = F \times d$	[1.1]	Work done by a force in the direction of displacement
• $E_k = \frac{1}{2}mv^2$	[1.2]	Kinetic energy
• $\text{K} = {}^\circ\text{C} + 273.15$	[1.3]	Converting between Celsius (°C) and Kelvin (K) temperature scales
• ${}^\circ\text{C} = \frac{5}{9}({}^\circ\text{F} - 32)$ or ${}^\circ\text{F} = \frac{9}{5}({}^\circ\text{C}) + 32$	[1.4]	Converting between Celsius (°C) and Fahrenheit (°F) temperature scales
• $\text{Density} = \frac{\text{mass}}{\text{volume}}$	[1.5]	Definition of density

Exam Prep

Here are some exam-style problems designed to test your understanding of the material in this chapter.

EP 1.1 Which of the following best describes the situation depicted in the figure? (**a**) molecules of a single pure element, (**b**) molecules of a mixture of two different elements, (**c**) molecules of a pure compound, or (**d**) a mixture of molecules of a compound and those of an element.



EP 1.2 Which of the following statements about the states of matter is *incorrect*? (**a**) The molecules in the gas phase are farther apart than those in a liquid phase of the same substance. (**b**) The molecules in a liquid have greater freedom to move than the molecules in a solid. (**c**) A solid can be readily compressed. (**d**) A gas will completely fill its container.

EP 1.3 Which of the following is a homogeneous mixture? (**a**) the air that we breathe (**b**) a bottle of pure water (**c**) molten iron (**d**) a bowl of oatmeal

EP 1.4 A certain mineral is described as containing the elements Ca, Fe, Mg, Si, and O. Which of the following elements is *not* in the mineral? (**a**) iron (**b**) silicon (**c**) calcium (**d**) carbon (**e**) magnesium

EP 1.5 A piece of metal is described as silvery in color, which is a ________ property, with a mass of 10 lb, which is an ________ property. Which of the following best fills in the blanks in the sentence? (**a**) physical, intensive (**b**) physical, extensive (**c**) chemical, intensive (**d**) chemical, extensive

EP 1.6 The following describe either physical or chemical changes of a substance:

(**i**) When heated, a mixture of hydrogen and oxygen gases reacts to form water.
(**ii**) When heated, liquid water turns into steam.
(**iii**) When heated, a piece of paper ignites and burns.

Which of these processes are *physical* changes? (**a**) Only one of the three is a physical change. (**b**) i and ii (**c**) i and iii (**d**) ii and iii (**e**) All three are physical changes.

EP 1.7 Which of the following statements about separation techniques is *true*? (**a**) Filtration can be used to separate a homogeneous mixture of two liquids. (**b**) Chromatography is a good technique for separating a mixture of two solids. (**c**) Separation techniques involve separating molecules into atoms. (**d**) Distillation is a technique that depends on the differences in the tendencies of substances to form gases.

EP 1.8 In a steam engine, water is converted to steam in a boiler and the steam is used to drive the wheels. Which of the following statements about this engine is or are correct?

(**i**) Both work and heat are forms of energy.
(**ii**) The energy used to convert the water to steam is heat.
(**iii**) When the steam drives the wheels, work is being done.

(**a**) Only one statement is correct. (**b**) Statements i and ii are correct. (**c**) Statements i and iii are correct. (**d**) Statements ii and iii are correct. (**e**) All three statements are correct.

EP 1.9 An apple falls from a tree to the ground. Which of the following correctly describes the changes in the apple's kinetic energy and gravitational potential energy as it first begins to fall from the tree? (**a**) Its kinetic energy increases and its gravitational potential energy increases. (**b**) Its kinetic energy decreases and its gravitational potential energy increases. (**c**) Its kinetic energy increases and its gravitational potential energy decreases. (**d**) Its kinetic energy decreases and its gravitational potential energy decreases.

EP 1.10 Which of the following weights would you expect to be suitable for weighing on an ordinary bathroom scale?

(**a**) 2.0×10^9 mg
(**b**) 2500 μg
(**c**) 5.0×10^{-4} kg
(**d**) 4.0×10^6 cg
(**e**) 5.5×10^8 dg

EP 1.11 Liquids A, B, and C boil at 80.1 °C, 181.4 °F, and 341.8 K, respectively. Which of the following is the correct ordering of the boiling points, from lowest to highest?

(**a**) A < B < C
(**b**) C < A < B
(**c**) B < C < A
(**d**) A < C < B

EP 1.12 Platinum, Pt, is one of the rarest of the metals. Worldwide annual production is only about 130 tons. Platinum has a density of 21.4 g/cm^3. If thieves were to steal platinum from a bank using a small truck with a maximum payload capacity of 900 lb, how many 1 L bars of the metal could they take? (**a**) 19 bars (**b**) 2 bars (**c**) 42 bars (**d**) 1 bar (**e**) 47 bars

EP 1.13 The density of copper is 8.96 g/cm^3. What is the mass in kg of a cube of copper metal that is 12.0 cm on each side? (**a**) 0.108 kg (**b**) 1.29 kg (**c**) 15.5 kg (**d**) 1.55×10^7 kg

EP 1.14 What is the kinetic energy of a 5.0-kg object moving at a speed of 20 m/s? (**a**) 50 J (**b**) 100 J (**c**) 250 J (**d**) 1000 J (**e**) 2000 J

EP 1.15 How many of the following quantities are *inexact* numbers: the number of μg in a gram; the number of square yards in a square mile; the height of a building; the density of aluminum; the number of seconds in a day; the number of cal in one J? (**a**) 1 (**b**) 2 (**c**) 3 (**d**) 4 (**e**) 5

EP 1.16 Which of the following statements about precision and accuracy of a scientific instrument is or are correct?

(**i**) An instrument can produce measurements that have good precision but poor accuracy.
(**ii**) An instrument that produces measurements with good accuracy must have good precision.
(**iii**) An instrument with good accuracy will lead to measurements close to the correct value.

(**a**) Only one statement is correct. (**b**) Statements i and ii are correct. (**c**) Statements i and iii are correct. (**d**) Statements ii and iii are correct. (**e**) All three statements are correct.

EP 1.17 An object is determined to have a mass of 0.01080 g. How many significant figures are there in this measurement? (**a**) 2 (**b**) 3 (**c**) 4 (**d**) 5 (**e**) 6

EP 1.18 A typical 400 m race in the Olympics is completed in a time between 40 and 50 s. A digital stopwatch is listed as having precision ±0.01 s. How many significant figures should be used in reporting the times for the race in s? (**a**) 1 (**b**) 2 (**c**) 3 (**d**) 4 (**e**) 5

EP 1.19 You are asked to determine the mass of a piece of copper using its reported density, 8.96 g/mL, and a 150-mL graduated cylinder. First, you add 105 mL of water to the graduated cylinder; then you place the piece of copper in the cylinder and record a volume of 137 mL. What is the mass of the copper reported with the correct number of significant figures?

(**a**) 287 g
(**b**) 3.5×10^{-3} g
(**c**) 286.72 g/mL
(**d**) 3.48×10^{-3} g
(**e**) 2.9×10^2 g

EP 1.20 To how many significant figures should the following expression be reported?

$$[(2.67 \times 10^3) - (4.7 \times 10^2)] \times (3.154 \times 10^4)$$

(**a**) 1 (**b**) 2 (**c**) 3 (**d**) 4 (**e**) 5

EP 1.21 A commercial Boeing 757 airliner has a typical cruising speed of 528 miles per hour. What is this speed in m/s? (Note: 1 mi = 1.609 km.) (**a**) 91.2 m/s (**b**) 236 m/s (**c**) 850 m/s (**d**) 3060 m/s

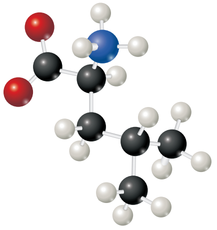
EP 1.22 The density of a particular flooring material is reported as 60.0 lb/ft^3. What is the density in kg/L? (**a**) 138 kg/L (**b**) 0.961 kg/L (**c**) 259 kg/L (**d**) 15.8 kg/L (**e**) 11.5 kg/L

EP 1.23 A ream of 8.5 in × 11 in "24 pound" printer paper contains exactly 500 sheets and has a mass of 6.00 lb. What is the mass in mg of a 1.00 cm × 1.00 cm square of the paper? (Note: 1 kg = 2.2046 lb and 1 in. = 2.54 cm.) (**a**) 1.50 mg (**b**) 9.02 mg (**c**) 22.9 mg (**d**) 58.2 mg

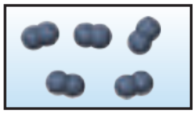
Exercises

Visualizing Concepts

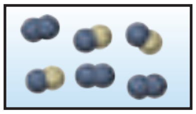
1.1 The molecule shown here is *leucine*, one of the amino acids that are the building blocks of proteins. The color key for the atoms is carbon (black), hydrogen (light gray), oxygen (red), and nitrogen (blue). (**a**) How many different elements are in a molecule of leucine? (**b**) How many carbon atoms are in a molecule of leucine? (**c**) Which element has the largest number of atoms in a leucine molecule? (**d**) What is the total number of atoms in a molecule of leucine? [Section 1.1]



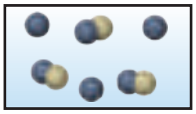
1.2 Which of the following figures represents (**a**) a pure element, (**b**) a mixture of two elements, (**c**) a pure compound, (**d**) a mixture of an element and a compound? (More than one picture might fit each description.) [Section 1.2]



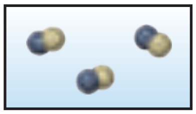
(i)



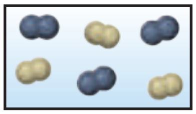
(ii)



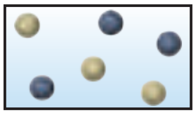
(iii)



(iv)



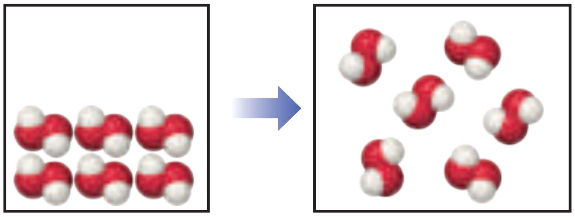
(v)



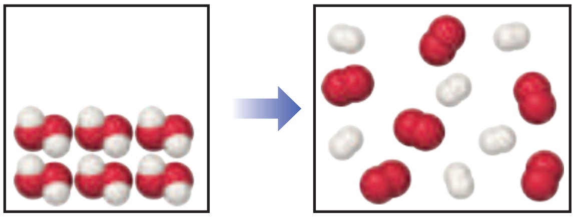
(vi)

1.3 Which of the following diagrams represents a chemical change? [Section 1.3]

(a)



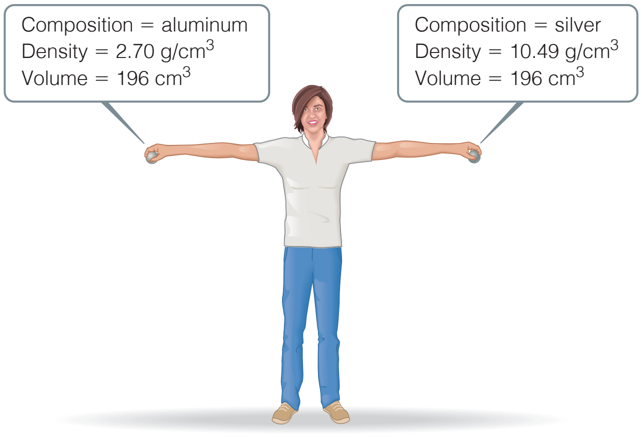
(b)



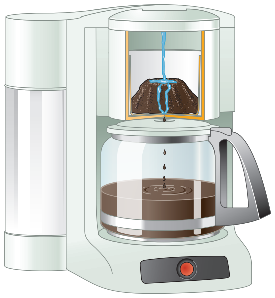
1.4 Musical instruments such as trumpets and trombones are made from an alloy called *brass*. Brass is composed of copper and zinc atoms and appears homogeneous under an optical microscope. The approximate composition of most brass objects is a 2:1 ratio of copper to zinc atoms, but the exact ratio varies somewhat from one piece of brass to another. (**a**) Would you classify brass as an element, a compound, a homogeneous mixture, or a heterogeneous mixture? (**b**) Would it be correct to say that brass is a solution? [Section 1.2]

1.5 Which of the following is the best description for the formation of frost on windows in the winter: (**i**) a solid is turning into a gas, (**ii**) a liquid is turning into a solid, (**iii**) a gas is turning into a liquid, (**iv**) a gas is turning into a solid, or (**v**) a solid is turning into a liquid? [Section 1.2]

1.6 Consider the two spheres shown here, one made of silver and the other of aluminum. (**a**) What is the mass of each sphere in kg? (**b**) The force of gravity acting on an object is $F = mg$, where m is the mass of an object and g is the acceleration of gravity ($9.8\ \text{m/s}^2$). How much work do you do on each sphere if you raise it from the floor to a height of 2.2 m? (**c**) Does the act of lifting the sphere off the ground increase the potential energy of the aluminum sphere by a larger, a smaller, or the same amount as the silver sphere? (**d**) If you release the spheres simultaneously, they will have the same velocity when they hit the ground. Will they have the same kinetic energy? If not, which sphere will have more kinetic energy? [Section 1.4]

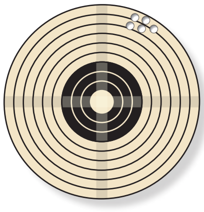


1.7 Is the separation method used in brewing a cup of coffee best described as distillation, filtration, or chromatography? [Section 1.3]

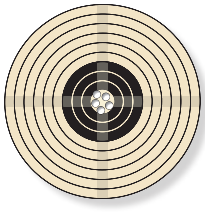


1.8 (**a**) Three spheres of equal size are composed of aluminum (density = $2.70\ \text{g/cm}^3$), silver (density = $10.49\ \text{g/cm}^3$), and nickel (density = $8.90\ \text{g/cm}^3$). List the spheres from lightest to heaviest. (**b**) Three cubes of equal mass are composed of gold (density = $19.32\ \text{g/cm}^3$), platinum (density = $21.45\ \text{g/cm}^3$), and lead (density = $11.35\ \text{g/cm}^3$). List the cubes from smallest to largest. [Section 1.5]

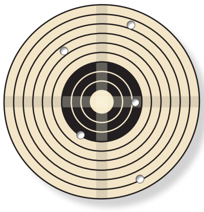
1.9 The three targets from a rifle range shown below were produced by: (**A**) the instructor firing a newly acquired target rifle; (**B**) the instructor firing his personal target rifle; and (**C**) a student who has fired his target rifle only a few times. (**a**) Comment on the accuracy and precision for each of these three sets of results. (**b**) For the A and C results in the future to look like those in B, what needs to happen? [Section 1.6]



A

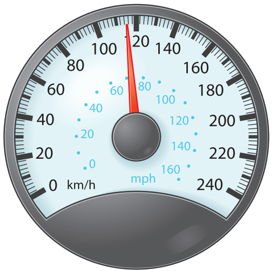


B

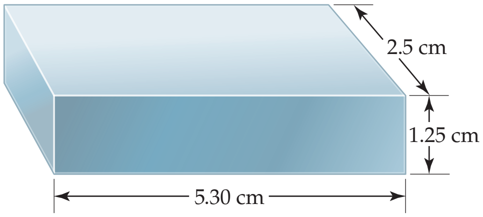


C

1.10 (**a**) What is the length of the pencil in the following figure if the ruler reads in centimeters? How many significant figures are there in this measurement? (**b**) An automobile speedometer with circular scales reading both miles per hour and kilometers per hour is shown. What speed is indicated, in both units? How many significant figures are in the measurements? [Section 1.6]



1.11 (**a**) How many significant figures should be reported for the volume of the metal bar shown here? (**b**) If the mass of the bar is 104.72 g, how many significant figures should be reported when its density is determined using the calculated volume? [Section 1.6]



1.12 Consider the jar of jelly beans in the photo. To get an estimate of the number of beans in the jar you weigh six beans and obtain masses of 3.15, 3.12, 2.98, 3.14, 3.02, and 3.09 g. Then you weigh the jar with all the beans in it, and obtain a mass of 2082 g. The empty jar has a mass of 653 g. Based on these data, estimate the number of beans in the jar. Justify the number of significant figures you use in your estimate. [Section 1.6]

Classification and Properties of Matter (Sections 1.1, 1.2, and 1.3)

1.13 Which of the following statements about atoms and molecules is *false*? (**a**) Atoms and molecules are forms of matter. (**b**) A molecule contains two or more atoms. (**c**) The atoms of two different elements can be the same. (**d**) Atoms and molecules have mass and occupy space. (**e**) A molecule can contain atoms from a single element.

1.14 The molecular model of a molecule has four black spheres, ten light gray spheres, and one red sphere. Which of the following statements is or are true? (**i**) There are 15 atoms in the molecule. (**ii**) The black spheres are atoms of the same element. (**iii**) There are atoms of three different elements in the molecule.

1.15 Classify each of the following as a pure substance or a mixture. If a mixture, indicate whether it is homogeneous or heterogeneous: (**a**) rice pudding, (**b**) seawater, (**c**) magnesium, (**d**) crushed ice.

1.16 Classify each of the following as a pure substance or a mixture. If a mixture, indicate whether it is homogeneous or heterogeneous: (**a**) gasoline vapor, (**b**) sugar crystals, (**c**) a hardboiled egg, (**d**) sawdust.

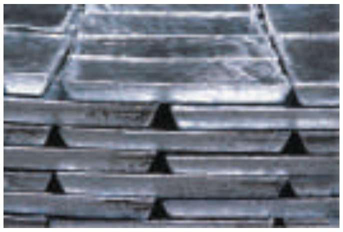
1.17 Give the chemical symbol or name for the following elements, as appropriate: (**a**) sulfur (**b**) gold (**c**) potassium (**d**) chlorine (**e**) copper (**f**) U (**g**) Ni (**h**) Na (**i**) Al (**j**) Si.

1.18 Give the chemical symbol or name for each of the following elements, as appropriate: (**a**) carbon (**b**) nitrogen (**c**) titanium (**d**) zinc (**e**) iron (**f**) P (**g**) Ca (**h**) He (**i**) Pb (**j**) Ag.

1.19 A solid white substance A is heated strongly in the absence of air. It decomposes to form a new white substance B and a gas C. The gas has exactly the same properties as the product obtained when carbon is burned in an excess of oxygen. Based on these observations, can we determine whether solids A and B and gas C are elements or compounds?

1.20 You are hiking in the mountains and find a shiny gold nugget. It might be the element gold, or it might be "fool's gold," which is a nickname for iron pyrite, FeS_2. Which of the following physical properties do you think would help determine if the shiny nugget is really gold—appearance, melting point, density, or physical state?

1.21 In the process of attempting to characterize a substance, a chemist makes the following observations: The substance is a silvery white, lustrous metal. It melts at 649 °C and boils at 1105 °C. Its density at 20 °C is 1.738 g/cm^3. The substance burns in air, producing an intense white light. It reacts with chlorine to give a brittle white solid. The substance can be pounded into thin sheets or drawn into wires. It is a good conductor of electricity. Which of these characteristics are physical properties, and which are chemical properties?



1.22 (**a**) Read the following description of the element zinc and indicate which are physical properties and which are chemical properties. Zinc melts at 420 °C. When zinc granules are added to dilute sulfuric acid, hydrogen is given off and the metal dissolves. Zinc has a hardness on the Mohs scale of 2.5 and a density of 7.13 g/cm^3 at 25 °C. It reacts slowly with oxygen gas at elevated temperatures to form zinc oxide, ZnO. (**b**) Which properties of zinc can you describe from the photo? Are these physical or chemical properties?

1.23 Label each of the following as either a physical process or a chemical process: (**a**) rusting of a metal can, (**b**) boiling a cup of water, (**c**) pulverizing an aspirin, (**d**) digesting a candy bar, (**e**) exploding of nitroglycerin?

1.24 A match is lit and held under a cold piece of metal. The following observations are made: (**a**) The match burns. (**b**) The metal gets warmer. (**c**) Water condenses on the metal. (**d**) Soot (carbon) is deposited on the metal. Which of these occurrences are due to physical changes, and which are due to chemical changes?

1.25 For each of the following processes, would filtration, distillation, or chromatography be the most effective separation technique: (**a**) removing the pulp from freshly squeezed orange juice, (**b**) separating a food dye into its individual components, (**c**) desalinating seawater?

1.26 Two beakers contain clear, colorless liquids. When the contents of the beakers are mixed, a white solid is formed. (**a**) Is this an example of a chemical or a physical change? (**b**) What would be the most convenient way to separate the newly formed white solid from the liquid mixture—filtration, distillation, or chromatography?

The Nature of Energy (Section 1.4)

1.27 Which of the following statements about energy, work, and heat is or are true? (**i**) Work and heat are both forms of energy. (**ii**) In order for work to be performed on an object, it must not move. (**iii**) Heat is energy that causes a change in temperature.

1.28 A soccer ball is dropped out of a window on the second floor of a dormitory to the ground below. Which of the following statements is or are true? (**i**) The kinetic energy of the ball is greatest at the time it is dropped out the window. (**ii**) As the ball falls, potential energy is converted into kinetic energy. (**iii**) The potential energy of the ball is due to the force of gravity acting on it.

1.29 (**a**) Calculate the kinetic energy (in joules) of a 1200-kg automobile moving at 18 m/s. (**b**) Convert this energy to calories. (**c**) If a truck weighing 2100 kg has the same kinetic energy as the automobile in part (a), what is its speed in m/s?

1.30 The mass of a helium atom is roughly four times that of a hydrogen atom. The mass of an oxygen atom is roughly 16 times that of a hydrogen atom. (**a**) For each of the following pairs, choose the one that has the greater kinetic energy: (i) a H atom moving at 1000 m/s or a He atom moving at 400 m/s, (ii) a H atom moving at 1000 m/s or an O atom moving at 400 m/s, (iii) a He atom moving at 1000 m/s or an O atom moving at 400 m/s. (**b**) A He atom is moving at 800 m/s. What is the speed of an O atom that has the same kinetic energy as the He atom?

1.31 Two positively charged particles are first brought close together and then released. Once released, the repulsion between particles causes them to move away from each other. (**a**) This is an example of potential energy being converted into what form of energy? (**b**) Does the electrostatic potential energy of the two particles increase or decrease as the distance between them is increased? (**c**) If the positive charge on the two particles were doubled at a fixed distance, would the electrostatic potential energy of the two particles increase, decrease, or stay the same?

1.32 For each of the following processes, does the potential energy of the object(s) increase or decrease? (**a**) The distance between two oppositely charged particles is increased. (**b**) Water is pumped from ground level to the reservoir of a water tower 30 m above the ground. (**c**) The bond in a chlorine molecule, Cl_2, is broken to form two chlorine atoms.

Units of Measurement (Section 1.5)

1.33 What exponential notation do the following abbreviations represent? (**a**) d (**b**) c (**c**) f (**d**) μ (**e**) M (**f**) k (**g**) n (**h**) m (**i**) p

1.34 Use appropriate metric prefixes to write the following measurements without use of exponents:

(**a**) 8.6×10^{-9} m (**d**) 1.81×10^{-2} s (**f**) 2.75×10^{-5} g

(**b**) 3.55×10^{4} g (**e**) 4.95×10^{6} m (**g**) 5.1×10^{2} cm

(**c**) 6.48×10^{-7} L

1.35 Make the following conversions: (**a**) 72 °F to °C, (**b**) 216.7 °C to °F, (**c**) 233 °C to K, (**d**) 315 K to °F, (**e**) 2500 °F to K, (**f**) 0 K to °F.

1.36 (**a**) The temperature on a warm summer day is 87 °F. What is the temperature in °C? (**b**) Many scientific data are reported at 25 °C. What is this temperature in kelvins and in degrees Fahrenheit? (**c**) Suppose that a recipe calls for an oven temperature of 400 °F. Convert this temperature to degrees Celsius and to kelvins. (**d**) Liquid nitrogen boils at 77 K. Convert this temperature to degrees Fahrenheit and to degrees Celsius.

1.37 (**a**) A sample of tetrachloroethylene, a liquid used in dry cleaning that is being phased out because of its potential to cause cancer, has a mass of 40.55 g and a volume of 25.0 mL at 25 °C. What is its density at this temperature? Will tetrachloroethylene float on water? (Materials that are less dense than water will float.) (**b**) Carbon dioxide (CO_2) is a gas at room temperature and pressure. However, carbon dioxide can be put under pressure to become a "supercritical fluid" that is a much safer dry-cleaning agent than tetrachloroethylene. At a certain pressure, the density of supercritical CO_2 is 0.469 g/cm^3. What is the mass of a 25.0-mL sample of supercritical CO_2 at this pressure?

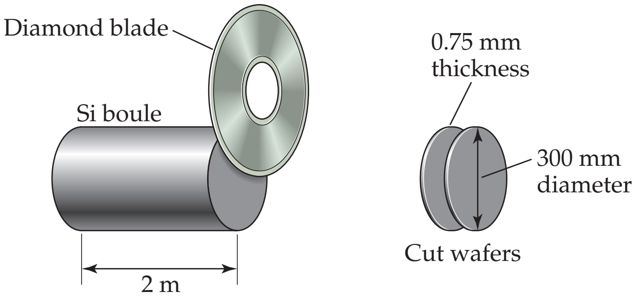
1.38 (**a**) A cube of an unknown metal that is 1.200 cm on a side has a mass of 17.66 g at 25 °C. What is its density in g/cm^3 at this temperature? (**b**) The density of magnesium metal is 1.74 g/cm^3 at 25 °C. What mass of magnesium displaces 75.0 mL of water at 25 °C? (**c**) Ethylene glycol is a viscous liquid with a density of 1.114 g/mL at 20 °C. Calculate the mass of 0.3750 L of ethylene glycol at this temperature.

1.39 (**a**) To identify a liquid substance, a student determined its density. Using a graduated cylinder, she measured out a 45-mL sample of the substance. She then measured the mass of the sample, finding that it weighed 38.5 g. She knew that the substance had to be either isopropyl alcohol (density 0.785 g/mL) or toluene (density 0.866 g/mL). What are the calculated density and the probable identity of the substance? (**b**) An experiment requires 78.1 g of benzene, a liquid whose density is 0.876 g/mL. Rather than weigh the sample on a balance, a chemist chooses to dispense the liquid using a graduated cylinder. What volume of the liquid should he use? (**c**) A cubic piece of metal measures 5.00 cm on each edge. If the metal is nickel, whose density is 8.90 g/cm^3, what is the mass of the cube?

1.40 (**a**) After the label fell off a bottle containing a clear liquid believed to be a solvent called tetrahydrofuran, a chemist measured the density of the liquid to verify its identity. A 25.0-mL portion of the liquid had a mass of 22.08 g. A chemistry handbook lists the density of tetrahydrofuran at 25 °C as 0.8833 g/mL. Is the calculated density in agreement with the tabulated value? (**b**) An experiment requires 50.0 g of a substance called *n*-hexane, whose density at 25 °C is 0.6606 g/mL. What volume of *n*-hexane should be used? (**c**) The density of titanium metal is 4.506 g/cm^3 at 20°C. What is the mass of a spherical ball of titanium with a diameter of 2.00 cm. [The volume of a sphere is $(4/3)\pi r^3$, where r is the radius.]

1.41 For January through April 2020, at the height of the global coronavirus pandemic, it is estimated that global emissions of carbon dioxide (CO_2) decreased by 940 million metric tons (1 metric ton = 1000 kg) compared to the same period in 2019. (**a**) Express this mass of CO_2 in grams without exponential notation, using an appropriate metric prefix. (**b**) Combustion of a gallon of gasoline generates about 8900 g of CO_2. How many gallons of gasoline would need to be burned to generate 940 million metric tons of CO_2? (**c**) Under normal room temperature conditions, the density of carbon dioxide gas is about 1.8 g/L. Express the volume of 940 million metric tons of CO_2 without exponential notation, using an appropriate metric prefix.

1.42 Silicon for computer chips is grown in large cylinders called "boules" that are 300 mm in diameter and 2 m in length, as shown. The density of silicon is 2.33 g/cm^3. Silicon wafers for making integrated circuits are sliced from a 2.0-m boule and are typically 0.75 mm thick and 300 mm in diameter. (**a**) How many wafers can be cut from a single boule? (**b**) What is the mass of a silicon wafer? (The volume of a cylinder is given by $\pi r^2 h$, where r is the radius and h is its height.)



Uncertainty in Measurement (Section 1.6)

1.43 Indicate which of the following are exact numbers: (**a**) the mass of a 3- by 5-in. index card, (**b**) the number of ounces in a pound, (**c**) the volume of a cup of Starbucks coffee, (**d**) the number of inches in a mile, (**e**) the number of microseconds in a week, (**f**) the number of pages in this book.

1.44 Indicate which of the following are exact numbers: (**a**) the mass of a 32-oz bag of sugar, (**b**) the number of students in your chemistry class, (**c**) the temperature of the surface of the Sun, (**d**) the mass of a postage stamp, (**e**) the number of milliliters in a cubic meter of water, (**f**) the average height of NBA basketball players.

1.45 What is the number of significant figures in each of the following measured quantities? (**a**) 820 g (**b**) 32.40 s (**c**) 90.01 mm (**d**) 0.00404 L (**e**) $3.50 \times 10^3\ \text{cm}^3$ (**f**) 400 kg

1.46 Indicate the number of significant figures in each of the following measured quantities: (**a**) 9.09 kg, (**b**) $6.040 \times 10^{-18}\ \text{m}^3$, (**c**) 0.0030 cm, (**d**) 290.00 K, (**e**) 12.8690 g, (**f**) $6.40 \times 10^4\ \text{m/s}$.

1.47 Round each of the following numbers to four significant figures and express the result in standard exponential notation: (**a**) 102.53070, (**b**) 656.980, (**c**) 0.008543210, (**d**) 0.000257870, (**e**) -0.0357202.

1.48 (**a**) The diameter of Earth at the equator is 7926.381 mi. Round this number to three significant figures and express it in standard exponential notation. (**b**) The circumference of Earth through the poles is 40,008 km. Round this number to four significant figures and express it in standard exponential notation.

1.49 Carry out the following operations and express the answers with the appropriate number of significant figures.

(**a**) $14.3505 + 2.65$
(**b**) $952.7 - 140.7389$
(**c**) $(3.29 \times 10^4)(0.2501)$
(**d**) $0.0588/0.677$

1.50 Carry out the following operations and express the answer with the appropriate number of significant figures.

(**a**) $320.5 - (6104.5/2.3)$
(**b**) $[(2.853 \times 10^3) - (1.200 \times 10^3)] \times 2.8954$
(**c**) $(0.0045 \times 20{,}000.0) + (2813 \times 12)$
(**d**) $863 \times [1255 - (3.45 \times 108)]$

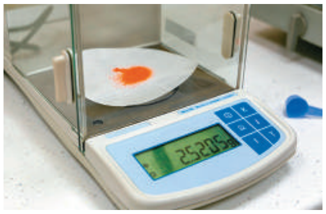
1.51 Carry out the following operations and express the answers in exponential notation with the appropriate number of significant figures.

(**a**) $6.754 \times 10^4 + 3.12 \times 10^5$
(**b**) $7.93 \times 10^6 - 1.6405 \times 10^4$
(**c**) $(8.67 \times 10^3 + 4.3 \times 10^1) \times 1.924 \times 10^{-2}$
(**d**) $(5.37 \times 10^{-3} - 8.44 \times 10^{-2})/(9.113 \times 10^{-3} - 7.46 \times 10^{-4})$

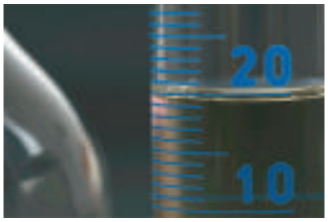
1.52 Carry out the following operations and express the answers in exponential notation with the appropriate number of significant figures.

(**a**) $2.791 \times 10^4 + 8.76 \times 10^3$
(**b**) $4.67 \times 10^2 - 5.4437 \times 10^4$
(**c**) $(2.481 \times 10^{-2} + 7.33 \times 10^{-4}) \times (1.924 \times 10^{-2} + 6.70)$
(**d**) $(1.3 \times 10^{-4} - 3.746 \times 10^{-2})/(1.3 \times 10^2 - 3.746 \times 10^4)$

1.53 You weigh an object on a balance and read the mass in grams according to the picture. How many significant figures are in this measurement?



1.54 You have a graduated cylinder that contains a liquid (see photograph). Write the volume of the liquid, in milliliters, using the proper number of significant figures.



Dimensional Analysis (Section 1.7)

1.55 What are the conversion factors needed to convert the following? (**a**) mm to nm (**b**) mg to kg (**c**) km to ft (**d**) in.^3 to cm^3

1.56 Determine the appropriate conversion factors for the following: (**a**) μm to mm, (**b**) ms to ns, (**c**) mi to km, (**d**) ft^3 to L.

1.57 (**a**) A bumblebee flies with a ground speed of 15.2 m/s. Calculate its speed in km/h. (**b**) The lung capacity of the blue whale is 5.0×10^3 L. Convert this volume into gallons. (**c**) The Statue of Liberty is 151 ft tall. Calculate its height in meters. (**d**) Bamboo can grow up to 60.0 cm/day. Convert this growth rate into inches per hour.

1.58 (**a**) The speed of light in a vacuum is 2.998×10^8 m/s. Calculate its speed in miles per hour. (**b**) The Sears Tower in Chicago is 1454 ft tall. Calculate its height in meters. (**c**) The Vehicle Assembly Building at the Kennedy Space Center in Florida has a volume of 3,666,500 m^3. Convert this volume to liters and express the result in standard exponential notation. (**d**) An individual suffering from a high cholesterol level in her blood has 242 mg of cholesterol per 100 mL of blood. If the total blood volume of the individual is 5.2 L, how many grams of total blood cholesterol does the individual's body contain?

1.59 Perform the following conversions: (**a**) 5.00 days to s, (**b**) 0.0550 mi to m, (**c**) \$1.89/gal to dollars per liter, (**d**) 0.510 in./ms to km/h, (**e**) 22.50 gal/min to L/s, (**f**) 0.02500 ft^3 to cm^3.

1.60 Carry out the following conversions: (**a**) 0.105 in. to mm, (**b**) 0.650 qt to mL, (**c**) 8.75 μm/s to km/h, (**d**) 1.955 m^3 to yd^3, (**e**) \$3.99/lb to dollars per kg, (**f**) 8.75 lb/ft^3 to g/mL.

1.61 (**a**) How many liters of wine can be held in a wine barrel whose capacity is 31 gal? (**b**) The recommended adult dose of Elixophyllin®, a drug used to treat asthma, is 6 mg/kg of body mass. Calculate the dose in milligrams for a 185-lb person. (**c**) If an automobile is able to travel 400 km on 47.3 L of gasoline, what is the gas mileage in miles per gallon? (**d**) When the coffee is brewed according to directions, a pound of coffee beans yields 50 cups of coffee (4 cups = 1 qt). How many kg of coffee are required to produce 200 cups of coffee?

1.62 (**a**) If an electric car is capable of going 225 km on a single charge, how many charges will it need to travel from Seattle, Washington, to San Diego, California, a distance of 1257 mi, assuming that the trip begins with a full charge? (**b**) If a migrating loon flies at an average speed of 14 m/s, what is its average speed in mi/h? (**c**) What is the engine piston displacement in liters of an engine whose displacement is listed as 450 in.^3? (**d**) In March 1989, the *Exxon Valdez* ran aground and spilled 240,000 barrels of crude petroleum off the coast of Alaska. One barrel of petroleum is equal to 42 gal. How many liters of petroleum were spilled?

1.63 The concentration of carbon monoxide in an urban apartment is 2800 $\mu\text{g/m}^3$. What mass of carbon monoxide in grams is present in a room measuring 13.5 ft × 17.1 ft × 10.0 ft?

1.64 The density of air at ordinary atmospheric pressure and 25 °C is 1.19 g/L. Each 1.00 g of air contains 0.21 g of oxygen gas. What is the mass, in kilograms, of the oxygen gas in a room that measures 15.1 ft × 19.6 ft × 9.0 ft?

1.65 The density of tungsten metal is 19.35 g/cm^3. (**a**) What is the density of tungsten in pounds per cubic foot? (**b**) A rectangular block of tungsten has a length of 4.00 cm, a width of 2.00 cm, and a height of 1.50 cm. Using the correct number of significant figures, what is the mass of the block in kg?

1.66 Aluminum has a density of 2.70 g/cm^3. (**a**) What is the density of aluminum in kg/m^3? (**b**) A package of aluminum foil contains 50 ft^2 of foil, which weighs approximately 8.0 oz. What is the approximate thickness of the foil in millimeters?

1.67 Gold can be hammered into extremely thin sheets called gold leaf. An architect wants to cover a 100 ft × 82 ft ceiling with gold leaf that is five-millionths of an inch thick. The density of gold is 19.32 g/cm^3. If gold costs \$1768 per troy ounce (1 troy ounce = 31.10348 g), how much will it cost the architect to buy the necessary gold?

1.68 A copper refinery produces a copper ingot weighing 150 lb. If the copper is drawn into wire whose diameter is 7.50 mm, how many feet of copper can be obtained from the ingot? The density of copper is 8.94 g/cm^3. (Assume that the wire is a cylinder whose volume $V = \pi r^2 h$, where r is its radius and h is its height or length.)

Additional Exercises

1.69 Classify each of the following as a pure substance, a solution, or a heterogeneous mixture: (**a**) a gold ingot, (**b**) a cup of coffee, (**c**) a wood plank, (**d**) a container of plain yogurt, (**e**) a block of dry ice, which is frozen carbon dioxide, (**f**) the gas in a scuba tank filled with 30% oxygen and 70% nitrogen.

1.70 (**a**) Which is more likely to eventually be shown to be incorrect: an hypothesis or a theory? (**b**) A(n) ________ reliably predicts the behavior of matter, while a(n) ________ provides an explanation for that behavior.

1.71 A sample of ascorbic acid (vitamin C) is synthesized in the laboratory. It contains 1.50 g of carbon and 2.00 g of oxygen. Another sample of ascorbic acid isolated from citrus fruits contains 6.35 g of carbon. According to the law of constant composition, how many grams of oxygen does it contain?

1.72 Ethyl chloride is sold as a liquid (see photo) under pressure for use as a local skin anesthetic. Ethyl chloride boils at 12 °C at atmospheric pressure. When the liquid is sprayed onto the skin, it boils off, cooling and numbing the skin as it vaporizes. (**a**) What changes of state are involved in this use of ethyl chloride? (**b**) What is the boiling point of ethyl chloride in degrees Fahrenheit? (**c**) The bottle shown contains 103.5 mL of ethyl chloride. The density of ethyl chloride at 25 °C is 0.765 g/cm^3. What is the mass of ethyl chloride in the bottle?

1.73 Two students determine the percentage of iron in a sample as a laboratory exercise. The true percentage is 34.43%. The students' results for three determinations are as follows:

(**1**) 34.44, 34.41, 34.46

(**2**) 34.51, 34.56, 34.48

(**a**) Calculate the average percentage for each set of data and state which set is the more accurate based on the average. (**b**) Precision can be judged by examining the average of the deviations from the average value for that data set. (Calculate the average value for each data set; then calculate the average value of the absolute deviations of each measurement from the average.) Which set is more precise?

1.74 What type of quantity (for example, length, volume, density) do the following units indicate? (**a**) mL (**b**) cm^2 (**c**) mm^3 (**d**) mg/L (**e**) ps (**f**) nm (**g**) K

1.75 Give the derived SI units for each of the following quantities in base SI units:

(**a**) acceleration = distance/time^2

(**b**) force = mass × acceleration

(**c**) work = force × distance

(**d**) pressure = force/area

(**e**) power = work/time

(**f**) velocity = distance/time

(**g**) energy = mass × (velocity)^2

1.76 Substance A melts at 350 °C, substance B melts at 580 K, and substance C melts at 650 °F. What is the correct order of the melting point temperatures of A, B, and C from lowest to highest?

1.77 The distance from Earth to the Moon is approximately 240,000 mi. (**a**) What is this distance in meters? (**b**) The peregrine falcon has been measured as traveling up to 350 km/h in a dive. If this falcon could fly to the Moon at this speed, how many seconds would it take? (**c**) The speed of light is 3.00×10^8 m/s. How long does it take for light to travel from Earth to the Moon and back again? (**d**) Earth travels around the Sun at an average speed of 29.783 km/s. Convert this speed to miles per hour.

1.78 Which of the following would you characterize as a pure or nearly pure substance? (**a**) baking powder (**b**) lemon juice (**c**) propane gas, used in outdoor gas grills (**d**) aluminum foil (**e**) ibuprofen (**f**) bourbon whiskey (**g**) helium gas (**h**) clear water pumped from a deep aquifer

1.79 (**a**) A baseball weighs 5.13 oz. What is the kinetic energy, in joules, of this baseball when it is thrown by a Major League pitcher at 95.0 mi/h? (**b**) By what factor will the kinetic energy change if the speed of the baseball is decreased to 55.0 mi/h? (**c**) What happens to the kinetic energy when the baseball is caught by the catcher? Is it converted mostly to heat or to some form of potential energy?

1.80 The U.S. quarter has a mass of 5.67 g and is approximately 1.55 mm thick. (**a**) How many quarters would have to be stacked to reach 575 ft, the height of the Washington Monument? (**b**) How much would this stack weigh? (**c**) How much money would this stack contain? (**d**) The U.S. National Debt Clock showed the outstanding national debt to be \$$2.625 \times 10^{13}$ in June 2020. How many stacks like the one described would be necessary to pay off this debt?

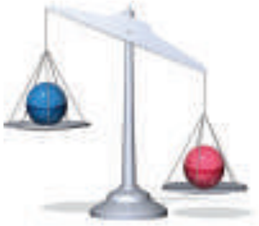
1.81 An Olympic swimming pool is 164 ft long and 82 ft wide. Assume that it is filled to a depth of 3.0 m, which is the Olympic recommendation. (**a**) What volume of water in gal is needed to fill the pool? (**b**) What volume of water in L is needed to fill the pool? (**c**) The U.S. Geological Survey estimates that in 2015 U.S. domestic use of water was 82 gal/day per person. Using this value for daily usage, for what length of time could the water used to fill an Olympic swimming pool provide the domestic water usage for a community of 25,000 residents?

1.82 A watt is a measure of power (the rate of energy change) that is equal to 1 J/s. (**a**) Calculate the number of joules in a kilowatt-hour. (**b**) An adult person radiates heat to the surroundings at about the same rate as a 100-watt electric incandescent light bulb. What is the total amount of energy in kcal radiated to the surroundings by an adult over a 24-h period?

1.83 By using estimation techniques, determine which of the following is the heaviest and which is the lightest: a 5-lb bag of potatoes, a 5-kg bag of sugar, or 1 gal of water (density = 1.0 g/mL).

1.84 The liquid substances mercury (density = 13.6 g/mL), water (1.00 g/mL), and cyclohexane (0.778 g/mL) do not form a solution when mixed but separate in distinct layers. Sketch how the liquids would position themselves in a test tube.

1.85 Two spheres of equal volume are placed on the scales as shown. (**a**) Which one is more dense? (**b**) When a blue sphere with a diameter that is 1.93 times the diameter of the red



sphere is put on the balance, the two spheres have the same mass. What is the ratio of the density of the blue sphere to that of the red sphere? (The volume of a sphere is $(4/3)\pi r^3$, where r is the radius.)

1.86 Water has a density of $0.997\ \mathrm{g/cm^3}$ at 25 °C; ice has a density of $0.917\ \mathrm{g/cm^3}$ at -10 °C. (**a**) If a soft-drink bottle whose volume is 1.50 L is completely filled with water and then frozen to -10 °C, what volume does the ice occupy? (**b**) Can the ice be contained within the bottle?

1.87 The mass of an empty oil drum is listed as 2.0×10^4 g. After a quantity of biodiesel fuel is added to the drum, the total mass is 7.05×10^5 g. (**a**) To how many significant figures should the mass of the biodiesel in the drum be reported? (**b**) The density of the biodiesel fuel is $0.875\ \mathrm{g/cm^3}$. What is the volume of biodiesel that has been added to the drum, in L?

1.88 A 32.65-g sample of a solid is placed in a flask. Toluene, in which the solid is insoluble, is added to the flask so that the total volume of solid and liquid together is 50.00 mL. The solid and toluene together weigh 58.58 g. The density of toluene at the temperature of the experiment is 0.864 g/mL. What is the density of the solid?

1.89 A thief plans to steal a platinum sphere with a radius of 28.9 cm from a museum. The density of platinum is $21.5\ \mathrm{g/cm^3}$. (**a**) What is the mass of the sphere in pounds? [The volume of a sphere is $V = (4/3)\pi r^3$.] (**b**) Is the thief likely to be able to walk off with the platinum sphere unassisted?

1.90 Automobile batteries contain sulfuric acid, which is commonly referred to as "battery acid." Calculate the number of grams of sulfuric acid in 1.00 gal of battery acid if the solution has a density of 1.28 g/mL and is 38.1% sulfuric acid by mass.

1.91 The total rate at which power is used by humans worldwide is approximately 18.4 TW (terawatts). The solar flux averaged over the sunlit half of Earth is $680\ \mathrm{W/m^2}$ (assuming no clouds). The area of Earth's disc as seen from the Sun is $1.28 \times 10^{14}\ \mathrm{m^2}$. The surface area of Earth is approximately 197,000,000 square miles. How much of Earth's surface would we need to cover with solar energy collectors to power the planet for use by all humans? Assume that the solar energy collectors can convert only 15% of the available sunlight into useful power.

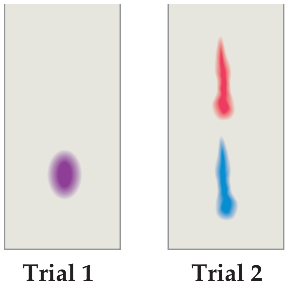
1.92 The potential energy of an object subject to gravity is given by $E_p = mgh$, where m is the mass of the object, g is the acceleration due to gravity ($9.8\ \mathrm{m/s^2}$), and h is the distance of the object from the surface of Earth. What is the kinetic energy and velocity of the silver sphere in Problem 1.6 at the moment it hits the ground? Assume that all of the sphere's initial potential energy is converted to kinetic energy at impact.

1.93 In 2005, J. Robin Warren and Barry J. Marshall shared the Nobel Prize in Physiology or Medicine for discovering the bacterium *Helicobacter pylori* and for establishing experimental proof that it plays a major role in gastritis and peptic ulcer disease. The story began when Warren, a pathologist, noticed that bacilli were associated with the tissues taken from patients suffering from ulcers. Look up the history of this case and describe Warren's first hypothesis. What sorts of evidence did it take to create a credible theory based on it?

1.94 A 25.0-cm-long cylindrical glass tube, sealed at one end, is filled with ethanol. The mass of ethanol needed to fill the tube is found to be 45.23 g. The density of ethanol is 0.789 g/mL. Calculate the inner diameter of the tube in centimeters.

1.95 Gold is alloyed (mixed) with other metals to increase its hardness in making jewelry. (**a**) Consider a piece of gold jewelry that weighs 9.85 g and has a volume of $0.675\ \mathrm{cm^3}$. The jewelry contains only gold and silver, which have densities of 19.3 and $10.5\ \mathrm{g/cm^3}$, respectively. If the total volume of the jewelry is the sum of the volumes of the gold and silver that it contains, calculate the percentage of gold (by mass) in the jewelry. (**b**) The relative amount of gold in an alloy is commonly expressed in units of carats. Pure gold is 24 carat, and the percentage of gold in an alloy is given as a percentage of this value. For example, an alloy that is 50% gold is 12 carat. State the purity of the gold jewelry in carats.

1.96 Paper chromatography is a simple but reliable method for separating a mixture into its constituent substances. You have a purple vegetable dye, and you want to determine whether the dye consists of multiple components. You try two different paper chromatography procedures and achieve the separations shown in the figure. Which of the following statements is or are true? (**i**) Trial 2 has achieved greater separation than has Trial 1. (**ii**) These experiments prove that the dye contains exactly two components. (**iii**) The separation of the two components in Trial 2 depends on how long the experiment is conducted.



1.97 Judge the following statements as true or false. If you believe a statement to be false, provide a corrected version.

(**a**) Air and water are both elements.

(**b**) All mixtures contain at least one element and one compound.

(**c**) Compounds can be decomposed into two or more other substances; elements cannot.

(**d**) Elements can exist in any of the three states of matter.

(**e**) When yellow stains in a kitchen sink are treated with bleach water, the disappearance of the stains is due to a physical change.

(**f**) A hypothesis is more weakly supported by experimental evidence than a theory.

(**g**) The number 0.0033 has more significant figures than 0.033.

(**h**) Conversion factors used in converting units always have a numerical value of one.

(**i**) Compounds always contain at least two different elements.

1.98 You are assigned the task of separating a desired granular material with a density of $3.62\ \mathrm{g/cm^3}$ from an undesired granular material that has a density of $2.04\ \mathrm{g/cm^3}$. You want to do this by shaking the mixture in a liquid in which the heavier material will fall to the bottom and the lighter material will float. A solid will float on any liquid that is more dense. Using an Internet-based source or a handbook of chemistry, find the densities of the following substances: carbon tetrachloride, hexane, benzene, and diiodomethane. Which of these liquids will serve your purpose, assuming no chemical interaction takes place between the liquid and the solids?

1.99 In 2009, a team from Northwestern University and Western Washington University reported the preparation of a new "spongy" material composed of nickel, molybdenum, and sulfur that excels at removing mercury from water. The density of this new material is $0.20\ \mathrm{g/cm^3}$, and its surface area is $1242\ \mathrm{m^2}$ per gram of material. (**a**) Calculate the volume of a 10.0-mg sample of this material. (**b**) Calculate the surface area for a 10.0-mg sample of this material. (**c**) A 10.0-mL sample of contaminated water had 7.748 mg of mercury in it. After treatment with 10.0 mg of the new spongy material, 0.001 mg of mercury remained in the contaminated water. What percentage of the mercury was removed from the water? (**d**) What is the final mass of the spongy material after the exposure to mercury?

2

ATOMS, MOLECULES, AND IONS

▲ The wonderful variety of colors and forms in nature result from only a dozen or so elements.

Everything in our universe is formed from only about 100 different kinds of fundamental building blocks, called **atoms**. In a sense, these different atoms are like the 26 letters of the English alphabet that join in different combinations to form the immense number of words in our language. But what rules govern the ways in which atoms combine? How do the properties of a substance relate to the kinds of atoms it contains? Indeed, what is an atom like, and what makes the atoms of one element different from those of another?

In this chapter, we introduce the basic structure of atoms and discuss the formation of molecules and ions. This knowledge provides you with the foundation you need to understand the chapters that follow.

WHAT'S AHEAD

2.1 ▶ The Atomic Theory of Matter Learn how scientists were able to postulate that atoms are the smallest building block of matter, long before they could be seen directly.

2.2 ▶ The Discovery of Atomic Structure Examine key experiments that led to the discovery of *electrons* and to the *nuclear model* of the atom.

2.3 ▶ The Modern View of Atomic Structure Learn how *atomic number* and *mass number* can be used to express the number of each subatomic particle—protons, neutrons, and electrons—in a given atom.

2.4 ▶ Atomic Weights Learn about the concept of *atomic weights* and how they are derived from the masses and abundances of individual atoms.

2.5 ▶ The Periodic Table Examine the organization of the *periodic table*, in which elements are put in order of increasing atomic number and grouped by chemical similarity.

2.6 ▶ Molecules and Molecular Compounds Explore the assemblies of atoms called *molecules* and learn how their compositions are represented by *empirical* and *molecular formulas*.

2.7 ▶ Ions and Ionic Compounds Realize that atoms can gain or lose electrons to form *ions* and learn how to use the periodic table to predict the charges on ions as well as the empirical formulas of *ionic* compounds.

2.8 ▶ Naming Inorganic Compounds Consider the systematic way in which substances are named, called *nomenclature*, and how this nomenclature is applied to inorganic compounds.

2.9 ▶ Some Simple Organic Compounds Become familiar with simple families of organic compounds, compounds containing carbon and hydrogen, and the nomenclature of these compounds.

2.1 The Atomic Theory of Matter

Learning Objectives

When you finish Section 2.1, you should be able to:

- List the basic postulates of Dalton's atomic theory.
- Use the laws derived from Dalton's atomic theory to explain simple chemical reactions.

Philosophers from the earliest times speculated about the nature of the fundamental "stuff" from which the world is made. Democritus (460–370 BCE) and other early Greek philosophers described the material world as being made up of tiny indivisible particles that they called *atomos*, meaning "indivisible" or "uncuttable." Later, however, Plato and Aristotle formulated the notion that there can be no ultimately indivisible particles, and the "atomic" view of matter faded for many centuries during which Aristotelean philosophy dominated Western culture.

The notion of atoms reemerged in Europe during the seventeenth century. As chemists learned to measure the amounts of elements that reacted with one another to form new substances, the ground was laid for an atomic theory that linked the idea of elements with the idea of atoms. That theory came from the work of John Dalton during the period 1803–1807. Dalton's atomic theory was based on four postulates (see **Figure 2.1**).

A good theory explains known facts; Dalton's theory explained several laws of chemical combination known at the time.

- The *law of constant composition* (Section 1.2), based on postulate 4:

  In a given compound, the relative numbers and kinds of atoms are constant.

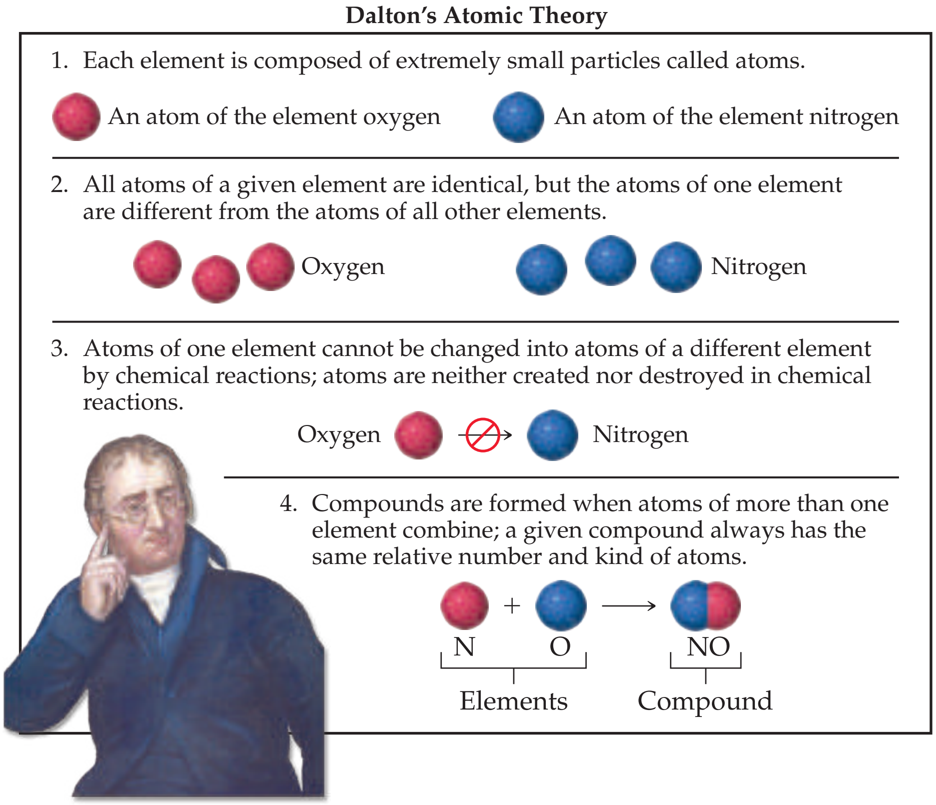
- The **law of conservation of mass,** based on postulate 3:

  The total mass of materials present after a chemical reaction is the same as the total mass present before the reaction.

A good theory also predicts new facts; Dalton used his theory to deduce

- The **law of multiple proportions:**

  If two elements A and B combine to form more than one compound, the masses of B that can combine with a given mass of A are in the ratio of small whole numbers.



Dalton's Atomic Theory

1. Each element is composed of extremely small particles called atoms.

An atom of the element oxygen
An atom of the element nitrogen

2. All atoms of a given element are identical, but the atoms of one element are different from the atoms of all other elements.

3. Atoms of one element cannot be changed into atoms of a different element by chemical reactions; atoms are neither created nor destroyed in chemical reactions.

4. Compounds are formed when atoms of more than one element combine; a given compound always has the same relative number and kind of atoms.

▶ **Figure 2.1 The four postulates of Dalton's atomic theory.*** John Dalton (1766–1844), the son of a poor English weaver, began teaching at age 12. He spent most of his years in Manchester, where he taught both grammar school and college. His lifelong interest in meteorology led him to study gases, then chemistry, and eventually atomic theory. Despite his humble beginnings, Dalton gained a strong scientific reputation during his lifetime.

---

*Dalton, "Atomic Theory" 1844.

We can illustrate this law by considering water and hydrogen peroxide, both of which consist of the elements hydrogen and oxygen. In forming water, 8.0 g of oxygen combines with 1.0 g of hydrogen. In forming hydrogen peroxide, 16.0 g of oxygen combines with 1.0 g of hydrogen. Thus, the ratio of the masses of oxygen per gram of hydrogen in the two compounds is 2:1. Using Dalton's atomic theory, we conclude that hydrogen peroxide contains twice as many atoms of oxygen per hydrogen atom than does water.

Self-Assessment Exercises

SAE 2.1 Which of the following statements is or are true?

(i) Atoms are the fundamental building blocks of matter.
(ii) According to Dalton, atoms of the same element can be different from one another.
(iii) According to Dalton, if two atoms are different, they must be atoms of different elements.

(**a**) i only (**b**) ii only (**c**) iii only (**d**) i and ii (**e**) i and iii

SAE 2.2 You are working at an elemental analysis lab. You decompose a 5.62 g sample of ammonia, NH_3, into its elements, yielding 4.63 g of nitrogen and 0.99 g of hydrogen. The next sample that arrives for analysis weighs 86.3 g and is supposed to contain only nitrogen and hydrogen. You decompose this sample and obtain 75.5 g of nitrogen and 10.8 g of hydrogen. Which of the following choices describes the best conclusion from these data?

(**a**) The second sample is ammonia because it only contains nitrogen and hydrogen. (**b**) The second sample cannot be ammonia because it must contain elements besides nitrogen and hydrogen. (**c**) The second sample cannot be ammonia because the ratio of masses of nitrogen to hydrogen is different from that for ammonia. (**d**) The second sample is ammonia because the ratio of masses of nitrogen to hydrogen is the same as that for the first ammonia sample.

2.2 | The Discovery of Atomic Structure

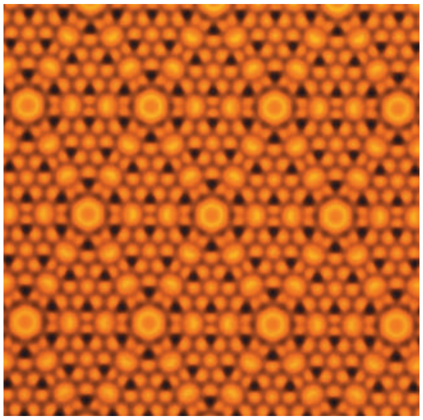
Dalton based his conclusions about atoms on chemical observations made in the laboratory. By assuming the existence of atoms, he was able to account for the laws of constant composition and multiple proportions. But neither Dalton nor those who followed him for the next hundred years had any direct evidence for the existence of atoms. Today, however, we can measure the properties of individual atoms and even obtain images of them (**Figure 2.2**).

As scientists developed methods for probing the nature of matter, the supposedly indivisible atom began to show signs of a more complex structure, and today we know that the atom is composed of **subatomic particles**. Before we summarize the current model, we briefly consider a few of the landmark discoveries that led to that model. We will see that the atom is composed in part of electrically charged particles, some with a positive charge and some with a negative charge. As we discuss the development of our current model of the atom, keep in mind this fact: *Particles with the same charge repel one another, whereas particles with opposite charges attract one another*.

Learning Objectives

When you finish Section 2.2, you should be able to:

- Describe the experiments that led to the discovery of the electron and its charge.
- Describe types of radioactivity and their properties.
- Describe the nuclear model of the atom and the experiments that led to its discovery.



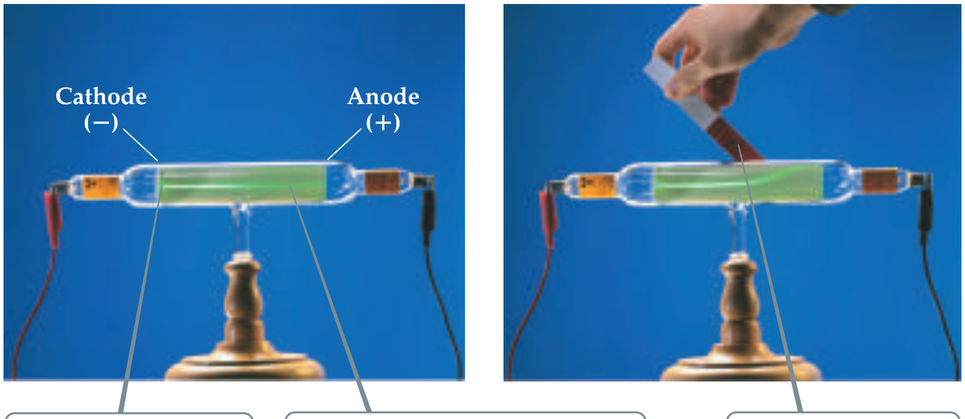
▲ **Figure 2.2** **The surface of silicon**, magnified by a factor of more than 2,000,000. This image was obtained from a technique called transmission electron microscopy. The silicon atoms have rearranged themselves to minimize their energy, resulting in this beautifully symmetric pattern.

Cathode Rays and Electrons

During the mid-1800s, scientists began to study electrical discharge through a glass tube pumped almost empty of air (**Figure 2.3**). When a high voltage was applied to the electrodes in the tube, radiation was produced between the electrodes. This radiation, called **cathode rays**, originated at the negatively charged electrode (the *cathode*) and traveled to the positively charged electrode (the *anode*). Although the rays could not be seen, their presence was detected because they caused certain materials to *fluoresce*—that is, to give off light.

Experiments showed that cathode rays are deflected by electric or magnetic fields in a way consistent with there being a stream of negative electrical charge. The British scientist J. J. Thomson (1856–1940) observed that cathode rays are the same regardless of the identity of the cathode material. In a paper published in 1897, Thomson described cathode rays as streams of negatively charged particles that we now call **electrons**.

Go Figure Does this experiment show that electrons flow from the cathode to the anode, or is it possible for electrons to flow from the anode to the cathode?



Cathode rays (electrons) move from the negative cathode to the positive anode.

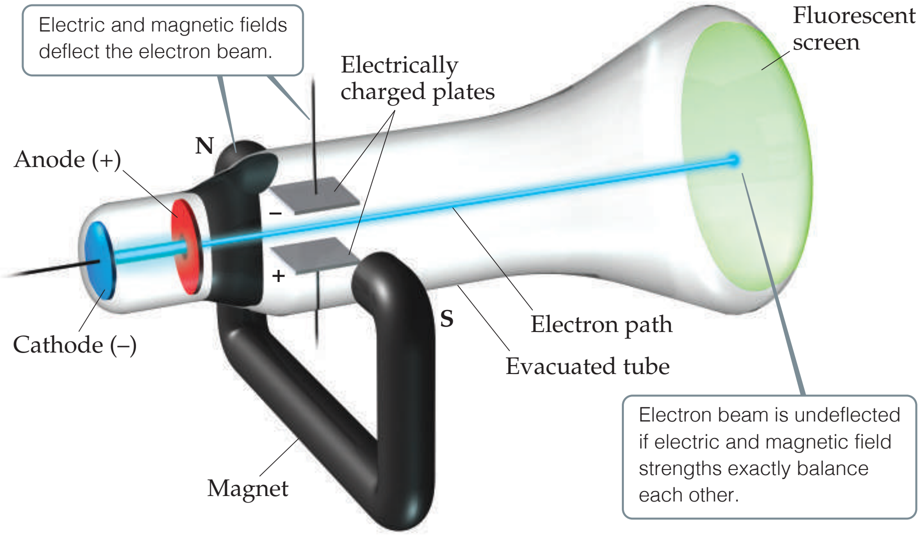
A fluorescent screen is placed in the tube to show the path of the cathode rays. The screen gives off light when a cathode ray strikes it.

The rays are deflected by a magnet.

▲ **Figure 2.3** **Cathode-ray tube.**

Thomson constructed a cathode-ray tube having a hole in the anode through which the cathode rays could pass. Electrically charged plates and a magnet were positioned perpendicular to the beam, and a fluorescent screen that would give off light when struck with a cathode ray was located at one end (**Figure 2.4**). Because the electron is a negatively charged particle, the electric field deflected the rays in one direction, whereas the magnetic field deflected them in the opposite direction. Thomson adjusted the strengths of the fields so that the effects balanced each other, allowing the electrons to travel in a straight path to the screen. Knowing the strengths that resulted in the straight path made

Go Figure If no magnetic field were applied, would you expect the electron beam to be deflected upward or downward by the electric field?

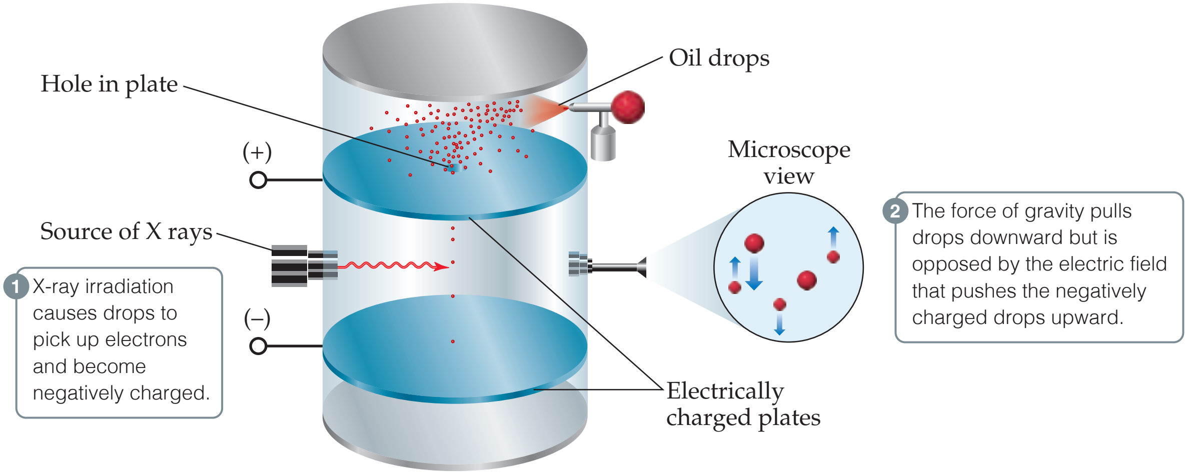


Electric and magnetic fields deflect the electron beam.

Electron beam is undeflected if electric and magnetic field strengths exactly balance each other.

▲ **Figure 2.4** **Cathode-ray tube with perpendicular magnetic and electric fields.** The cathode rays (electrons) originate at the cathode and are accelerated toward the anode, which has a hole in its center. A narrow beam of electrons passes through the hole and travels to the fluorescent screen that glows when struck by a cathode ray.

Go Figure Are the masses of the oil drops changed significantly when electrons accumulate on them?



① X-ray irradiation causes drops to pick up electrons and become negatively charged.

② The force of gravity pulls drops downward but is opposed by the electric field that pushes the negatively charged drops upward.

▲ **Figure 2.5** **Millikan's oil-drop experiment to measure the charge of the electron.** Small drops of oil are allowed to fall between electrically charged plates. Millikan measured how varying the voltage between the plates affected the rate of fall. From these data he calculated the negative charge on the drops. Because the charge on any drop was always some integral multiple of 1.602×10^{-19} C, Millikan deduced this value to be the charge of a single electron.

it possible to calculate a value of 1.76×10^8 coulombs* per gram for the ratio of the electron's electrical charge to its mass.

Once the charge-to-mass ratio of the electron was known, measuring either quantity allowed scientists to calculate the other. In 1909, Robert Millikan (1868–1953) of the University of Chicago succeeded in measuring the charge of an electron by performing the experiment described in **Figure 2.5**. He then calculated the mass of the electron by using his experimental value for the charge, 1.602×10^{-19} C, and Thomson's charge-to-mass ratio, 1.76×10^8 C/g:

$$\text{Electron mass} = \frac{1.602 \times 10^{-19}\,\cancel{\text{C}}}{1.76 \times 10^{8}\,\cancel{\text{C}}/\text{g}} = 9.10 \times 10^{-28}\ \text{g}$$

This result agrees well with the currently accepted value for the electron mass, 9.10938×10^{-28} g. This mass is about 2000 times smaller than that of hydrogen, the lightest atom.

Radioactivity

In 1896, the French scientist Henri Becquerel (1852–1908) discovered that a compound of uranium spontaneously emits high-energy radiation. This spontaneous emission of radiation is called **radioactivity**. At Becquerel's suggestion, Marie Curie (**Figure 2.6**) and her husband, Pierre, began experiments to identify and isolate the source of radioactivity in the compound. They concluded that it was the uranium atoms.

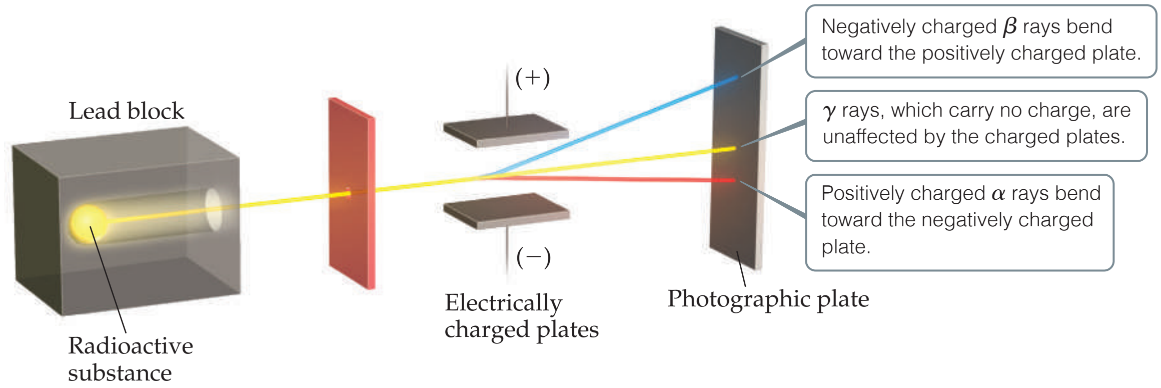
Further study of radioactivity, principally by the British scientist Ernest Rutherford (1871–1937), revealed three types of radiation: alpha (α), beta (β), and gamma (γ). Rutherford was a very important figure in this period of atomic science. After working at Cambridge University with J. J. Thomson, he moved to McGill University in Montreal, where he did research on radioactivity that led to his 1908 Nobel Prize in Chemistry. In 1907, he returned to England as a faculty member at Manchester University, where he conducted the α-particle scattering experiments that we describe in the next subsection.

▲ **Figure 2.6** **Marie Sklodowska Curie (1867–1934).** In 1903, Henri Becquerel, Marie Curie, and her husband, Pierre, were jointly awarded the Nobel Prize in Physics for their pioneering work on radioactivity (a term she introduced). In 1911, Marie Curie won a second Nobel Prize, this time in Chemistry, for her discovery of the elements polonium and radium.

---

*The coulomb (C) is the SI unit for electrical charge.

Go Figure What is the significance of the observation that the alpha and beta rays are bent in opposite directions?



Negatively charged β rays bend toward the positively charged plate.

γ rays, which carry no charge, are unaffected by the charged plates.

Positively charged α rays bend toward the negatively charged plate.

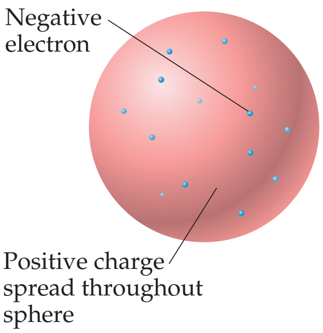
▲ **Figure 2.7** **Behavior of alpha (α) beta (β), and gamma (γ) rays in an electric field.**

Rutherford showed that the paths of α and β radiation are bent by an electric field, although in opposite directions, while γ radiation is unaffected by the field (**Figure 2.7**). From this finding he concluded that α and β rays consist of fast-moving electrically charged particles. In fact, β particles are nothing more than high-speed electrons that can be considered the radioactive equivalent of cathode rays. Because of their negative charge, they are attracted to a positively charged plate. The α particles have a positive charge and are attracted to a negative plate. In units of the charge of the electron, β particles have a charge of $1-$, whereas α particles have a charge of $2+$. Each α particle has a mass about 7400 times that of an electron. Gamma radiation is high-energy electromagnetic radiation similar to X rays; it does not consist of particles and it carries no charge.

The Nuclear Model of the Atom

With growing evidence that the atom was composed of smaller particles, scientists tried to explain how the particles fit together. During the early 1900s, Thomson reasoned that because electrons contribute only a very small fraction of an atom's mass, they probably are responsible for an equally small fraction of the atom's size. He proposed that the atom consists of a uniform positive sphere of matter in which the mass is evenly distributed and in which the electrons are embedded like raisins in a pudding or seeds in a watermelon (**Figure 2.8**). This *plum-pudding model*, named after a traditional English dessert, was very short-lived.

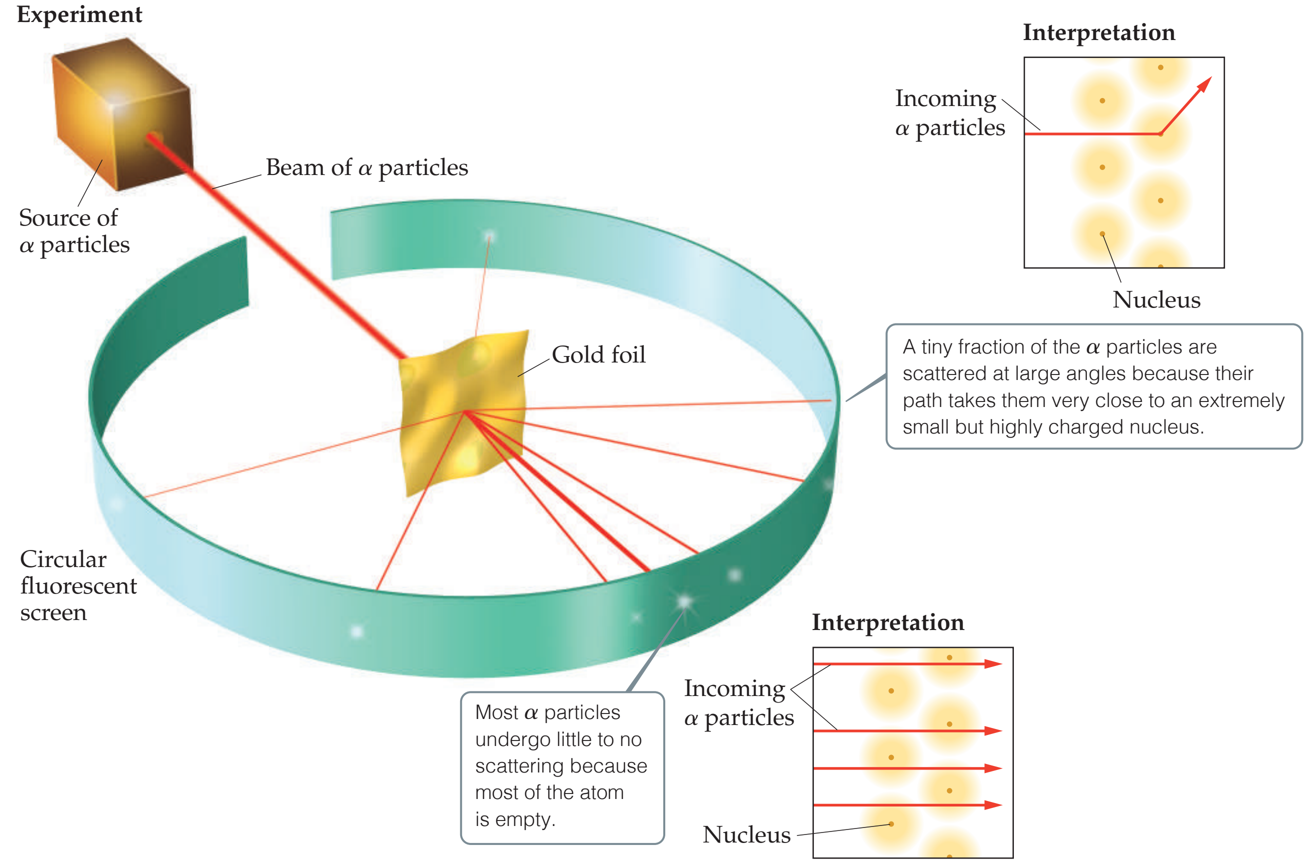
In 1910, Rutherford was studying the angles at which α particles were deflected, or *scattered*, as they passed through a thin sheet of gold foil (**Figure 2.9**). He discovered that almost all the particles passed directly through the foil without deflection, with a few particles deflected about 1°, consistent with Thomson's plum-pudding model. For the sake of completeness, Rutherford suggested that Ernest Marsden (1889–1970), an undergraduate student working in the laboratory, look for scattering at large angles. To everyone's surprise, a small amount of scattering was observed at large angles, with some particles scattered back in the direction from which they had come. The explanation for these results was not immediately obvious, but they were clearly inconsistent with Thomson's plum-pudding model.



▲ **Figure 2.8** **J. J. Thomson's plum-pudding model of the atom.** Ernest Rutherford and Ernest Marsden proved this model wrong.

Rutherford explained the results by postulating the **nuclear model** of the atom, in which most of the mass of each gold atom and all of its positive charge reside in a very small, extremely dense region that he called the **nucleus**. He postulated further that most of the volume of an atom is empty space in which electrons move around the nucleus. In the α-scattering experiment, most of the particles passed through the foil unscattered because they did not encounter the minute nucleus of any gold atom. Occasionally, however, an α particle came close to a gold nucleus. In such encounters,

Go Figure Predict where the spots on the circular fluorescent screen would be if the plum-pudding model of the atom was correct.



A tiny fraction of the α particles are scattered at large angles because their path takes them very close to an extremely small but highly charged nucleus.

Most α particles undergo little to no scattering because most of the atom is empty.

▲ **Figure 2.9 Rutherford's α-scattering experiment.** When α particles pass through a gold foil, most pass through undeflected, but some are scattered, a few at very large angles. The nuclear model of the atom explains why a few α particles are deflected at large angles. Although the nuclear atom has been depicted here as a yellow sphere, it is important to realize that most of the space around the nucleus contains only the low-mass electrons.

the repulsion between the highly positive charge of the gold nucleus and the positive charge of the α particle was strong enough to deflect the particle, as shown in Figure 2.9.

Subsequent experiments led to the discovery of positive particles (**protons**) and neutral particles (**neutrons**) in the nucleus. Protons were discovered in 1919 by Rutherford and neutrons in 1932 by British scientist James Chadwick (1891–1972). Thus, the atom is composed of electrons, protons, and neutrons.

Self-Assessment Exercises

SAE 2.3 Which of the following statements is false? (**a**) Electrons are subatomic particles that bear a negative charge. (**b**) Millikan's oil-drop experiment showed that one electron has a charge of 1.602×10^{-19} coulombs. (**c**) Thomson's cathode-ray experiments showed that electrons do have mass. (**d**) One electron has a mass of about a picogram, 10^{-12} g.

SAE 2.4 What can you conclude from the observation that gamma radiation is not deflected by an electric field? (**a**) Gamma rays have no mass. (**b**) Gamma rays have no charge. (**c**) Gamma rays have neither mass nor charge.

SAE 2.5 Which of the following statements is false? (**a**) The nucleus consists of protons and neutrons. (**b**) The nucleus is the densest part of the atom. (**c**) Rutherford's gold foil experiment proved that the plum-pudding model of the atom is correct. (**d**) To remain electrically neutral, all atoms should contain equal numbers of electrons and protons.

2.3 | The Modern View of Atomic Structure

Learning Objectives

When you finish Section 2.3, you should be able to:

- Compare the relative charges and masses of protons, neutrons, and electrons.
- Describe the interactions between protons, neutrons, and electrons that are responsible for holding atoms together.
- Correlate an isotope's chemical symbol with the number of protons, neutrons, and electrons it contains.

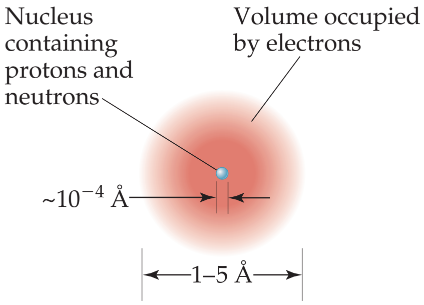
Since Rutherford's time, the list of particles that make up nuclei has grown and continues to increase as physicists have learned more and more about atomic nuclei. Examples of those subatomic particles include quarks, leptons, and bosons.* As chemists, however, we can take a simple view of the atom because only three subatomic particles—the proton, neutron, and electron—have a bearing on chemical behavior.

As noted earlier, the charge of an electron is -1.602×10^{-19} C. The charge of a proton is opposite in sign but equal in magnitude to that of an electron: $+1.602 \times 10^{-19}$ C. The quantity 1.602×10^{-19} C is called the **electronic charge**. For convenience, the charges of atomic and subatomic particles are usually expressed as multiples of this charge rather than as coulombs. Thus, the charge of an electron is 1− and that of a proton is 1+. Neutrons are electrically neutral (which is how they received their name). *Every atom has an equal number of electrons and protons, so atoms have no net electrical charge.*

Protons and neutrons reside in the tiny nucleus of the atom. The vast majority of an atom's volume is the space in which the electrons reside (Figure 2.10). Most atoms have diameters between 1×10^{-10} m (100 pm) and 5×10^{-10} m (500 pm). A convenient non-SI unit of length used for atomic dimensions is the **angstrom** (Å), where $1 \text{ Å} = 1 \times 10^{-10} \text{ m} = 100$ pm. Thus, atoms have diameters of approximately 1–5 Å. The diameter of a chlorine atom, for example, is 200 pm, or 2.0 Å.

Go Figure

What is the approximate diameter of the nucleus in units of pm?



Nucleus containing protons and neutrons
Volume occupied by electrons
~10^{-4} Å
1–5 Å

▲ **Figure 2.10 The structure of the atom.** A cloud of rapidly moving electrons occupies most of the volume of the atom. The nucleus occupies a tiny region at the center of the atom and is composed of the protons and neutrons. The nucleus contains virtually all the mass of the atom.

Electrons are attracted to the protons in the nucleus by the electrostatic force that exists between particles of opposite electrical charge. In later chapters, we show that the strength of the attractive forces between electrons and nuclei can be used to explain many of the differences among different elements.

Atoms have extremely small masses. The mass of the heaviest known atom, for example, is approximately 4×10^{-22} g. Because it would be cumbersome to express such small masses in grams, we use the **atomic mass unit** (amu),* where 1 amu $= 1.66054 \times 10^{-24}$ g. A proton has a mass of 1.0073 amu, a neutron 1.0087 amu, and an electron 5.486×10^{-4} amu (Table 2.1). Because it takes 1836 electrons to equal the mass of one proton, and 1839 electrons to equal the mass of a single neutron, the nucleus accounts for nearly the entire mass of an atom.

TABLE 2.1 Comparison of the Proton, Neutron, and Electron

Particle	Charge	Mass (amu)
Proton	Positive (1+)	1.0073
Neutron	None (neutral)	1.0087
Electron	Negative (1−)	5.486×10^{-4}

The diameter of an atomic nucleus is approximately 10^{-4} Å, only a small fraction of the diameter of the atom as a whole. You can appreciate the relative sizes of the atom and its nucleus by imagining that if the hydrogen atom were as large as a football stadium, the nucleus would be the size of a marble. Because the tiny nucleus carries most of the mass of the atom in such a small volume, it has an incredibly high density—on the order of 10^{13}–10^{14} g/cm^3. A candy bar of that density would weigh over 2.5 billion tons!

Figure 2.10 incorporates the features we have just discussed. The significance of representing the region containing electrons as an indistinct cloud will become clear in later chapters when we consider the energies and spatial arrangements of the electrons. For now, however, we have all the information we need to discuss many topics that form the basis of everyday uses of chemistry.

---

*The electron is an elementary particle that cannot be divided into smaller particles, whereas protons and neutrons are made up of smaller particles called quarks.

*The SI abbreviation for the atomic mass unit is u. We use the more common abbreviation amu.

Atomic Numbers, Mass Numbers, and Isotopes

What makes an atom of one element different from an atom of another element? The atoms of each element have a *characteristic number of protons*. The number of protons in an atom of any particular element is called that element's **atomic number**. Because an atom has no net electrical charge, the number of electrons it contains must equal the number of protons. All atoms of carbon, for example, have six protons and six electrons, whereas all atoms of oxygen have eight protons and eight electrons. Thus, carbon has atomic number 6, whereas oxygen has atomic number 8. The atomic number of each element is listed with the name and symbol of the element on the front inside cover of the text.

Atoms of a given element can differ in the number of neutrons they contain and, consequently, in mass. For example, while most atoms of carbon have six neutrons, some have more and some have less. The symbol ${}^{12}_{6}\text{C}$ (read "carbon twelve," carbon-12) represents the carbon atom containing six protons and six neutrons, whereas carbon atoms that contain six protons and eight neutrons have mass number 14, are represented as ${}^{14}_{6}\text{C}$, and are referred to as carbon-14.

Sample Exercise 2.1

Atomic Size

The diameter of a U.S. dime is 17.9 mm, and the diameter of a silver atom is 2.88 Å. How many silver atoms could be arranged side by side across the diameter of a dime?

SOLUTION

The unknown is the number of silver (Ag) atoms. Using the relationship 1 Ag atom = 2.88 Å as a conversion factor relating number of atoms and distance, we start with the diameter of the dime, first converting this distance into angstroms and then using the diameter of the Ag atom to convert distance to number of Ag atoms:

$$\begin{aligned}\text{number of Ag atoms} &= (17.9\,\cancel{\text{mm}})\left(\frac{10^{-3}\,\cancel{\text{m}}}{1\,\cancel{\text{mm}}}\right)\left(\frac{1\,\cancel{\text{\AA}}}{10^{-10}\,\cancel{\text{m}}}\right)\left(\frac{1\ \text{Ag atom}}{2.88\,\cancel{\text{\AA}}}\right)\\ &= 6.22\times10^{7}\ \text{Ag atoms}\end{aligned}$$

That is, 62.2 million silver atoms could sit side by side across a dime!

▶ Practice Exercise

The diameter of a carbon atom is 1.54 Å. (**a**) Express this diameter in picometers. (**b**) How many carbon atoms could be aligned side by side across the width of a pencil line that is 0.20 mm wide?

A CLOSER LOOK Basic Forces

Four basic forces are known in nature: (1) gravitational, (2) electromagnetic, (3) strong nuclear, and (4) weak nuclear. *Gravitational forces* are attractive forces that act between all objects in proportion to their masses. Gravitational forces between atoms or between subatomic particles are so small that they are of no chemical significance.

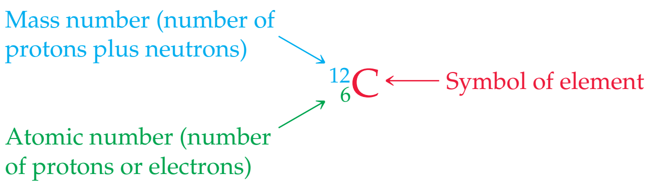
Electromagnetic forces are attractive or repulsive forces that act between either electrically charged or magnetic objects. The magnitude of the electric force between two charged particles is given by *Coulomb's law:* $F = kQ_1Q_2/d^2$, where Q_1 and Q_2 are the magnitudes of the charges on the two particles, d is the distance between their centers, and k is a constant determined by the units for Q and d. (Section 1.4) A negative value for the force indicates attraction, whereas a positive value indicates repulsion. Electric forces are of primary importance in determining the chemical properties of elements.

All nuclei except those of hydrogen atoms contain two or more protons. Because like charges repel, electrical repulsion would cause the protons to fly apart if the *strong nuclear force* did not keep them together. As the name implies, this force can be quite strong but only when particles are extremely close together, as are the protons and neutrons in a nucleus. At this distance, the attractive strong nuclear force is stronger than the positive–positive repulsive electric force and holds the nucleus together.

The *weak nuclear force* is weaker than the electric force and the strong nuclear force but stronger than the gravitational force. We are aware of its existence only because it shows itself in certain types of radioactivity.

Related Exercise: 2.114

The atomic number is indicated by the subscript; the superscript, called the **mass number**, is the number of protons plus neutrons in the atom:



Mass number (number of protons plus neutrons)
12
6
C
Symbol of element
Atomic number (number of protons or electrons)

Because all atoms of a given element have the same atomic number, the subscript is redundant and is often omitted. Thus, the symbol for carbon-12 can be represented simply as ^{12}C.

Atoms with identical atomic numbers but different mass numbers (that is, the same number of protons but different numbers of neutrons) are called **isotopes** of one another. Several isotopes of carbon are listed in **Table 2.2**. We generally use the notation with superscripts only when referring to a particular isotope of an element. It is important to keep in mind that the isotopes of any given element are all alike chemically. A carbon dioxide molecule that contains a ^{13}C atom behaves for all practical purposes identically to one that contains a ^{12}C atom.

TABLE 2.2 Some Isotopes of Carbon[a]

Symbol	Number of Protons	Number of Electrons	Number of Neutrons
^{11}C	6	6	5
^{12}C	6	6	6
^{13}C	6	6	7
^{14}C	6	6	8

[a] Almost 99% of the carbon found in nature is ^{12}C.

Sample Exercise 2.2

Determining the Number of Subatomic Particles in Atoms

How many protons, neutrons, and electrons are in an atom of (a) ^{197}Au, (b) strontium-90?

SOLUTION

(**a**) The superscript 197 is the mass number (protons + neutrons). According to the list of elements given on the front inside cover, gold has atomic number 79. Consequently, an atom of ^{197}Au has 79 protons, 79 electrons, and $197 - 79 = 118$ neutrons.

(**b**) The atomic number of strontium is 38. Thus, all atoms of this element have 38 protons and 38 electrons. The strontium-90 isotope has $90 - 38 = 52$ neutrons.

Practice Exercise

How many protons, neutrons, and electrons are in an atom of (**a**) ^{138}Ba, (**b**) phosphorus-31?

Sample Exercise 2.3

Writing Symbols for Atoms

Magnesium has three isotopes with mass numbers 24, 25, and 26. (**a**) Write the complete chemical symbol (superscript and subscript) for each. (**b**) How many neutrons are in an atom of each isotope?

SOLUTION

(**a**) Magnesium has atomic number 12, so all atoms of magnesium contain 12 protons and 12 electrons. The three isotopes are therefore represented by ${}^{24}_{12}Mg$, ${}^{25}_{12}Mg$, and ${}^{26}_{12}Mg$.

(**b**) The number of neutrons in each isotope is the mass number minus the number of protons. The numbers of neutrons in an atom of each isotope are therefore 12, 13, and 14, respectively.

Practice Exercise

Give the complete chemical symbol for the atom that contains 82 protons, 82 electrons, and 126 neutrons.

Self-Assessment Exercises

SAE 2.6 Which pairing of subatomic particle with charge is correct? (**a**) proton/1− (**b**) neutron/1+ (**c**) electron/0 (**d**) electron/1+ (**e**) electron/0

SAE 2.7 The density of the nucleus of a particular atom is 1×10^{13} g/cm^3. Given that the diameter of a nucleus is 1×10^{-4} Å, estimate the mass of the nucleus, assuming it is a sphere. (**a**) 10^{13} g (**b**) 41889 g (**c**) 4.19×10^{-23} g (**d**) 5.23×10^{-24} g

SAE 2.8 If the nucleus is so dense and full of positively charged protons, why doesn't it fly apart due to electrostatic repulsions between protons? (**a**) The negatively charged electrons in the nucleus lead to electrostatic attractions that keep it together. (**b**) The neutrons act as electrostatic "glue" to reduce electrostatic repulsion between protons in the nucleus. (**c**) The strong nuclear force keeps the nucleus together in spite of electrostatic repulsions between protons. (**d**) Actually, nuclei do disintegrate around us all the time.

SAE 2.9 Which of the following is the correct chemical symbol for uranium-235, the radioactive isotope that is the basis for many nuclear weapons? (**a**) $^{235}_{92}U$ (**b**) $^{92}_{235}U$ (**c**) $^{143}_{92}U$ (**d**) $^{235}_{92}Ur$

2.4 | Atomic Weights

Atoms are small pieces of matter, so they have mass. In this section, we discuss the mass scale used for atoms and introduce the concept of *atomic weights*.

Learning Objectives

When you finish Section 2.4 you should be able to:

- Describe the relationship between the atomic weight of an element and the weights and abundances of the naturally occurring isotopes of that element.
- Interconvert between atomic weights and isotopic abundances for an element.
- Describe the principles of mass spectrometry.
- Interpret/predict data from a mass spectrometer.

The Atomic Mass Scale

Scientists of the nineteenth century were aware that atoms of different elements have different masses. They found, for example, that each 100.0 g of water contains 11.1 g of hydrogen and 88.9 g of oxygen. Thus, water contains $88.9/11.1 = 8$ times as much oxygen, by mass, as hydrogen. Once scientists understood that water contains two hydrogen atoms for each oxygen atom, they concluded that an oxygen atom must have $2 \times 8 = 16$ times as much mass as a hydrogen atom. Hydrogen, the lightest atom, was arbitrarily assigned a relative mass of 1 (no units). Atomic masses of other elements were at first determined relative to this value. Thus, oxygen was assigned an atomic mass of 16.

Today we can determine the masses of individual atoms with a high degree of accuracy and precision. For example, we know that the ^1H atom has a mass of 1.6735×10^{-24} g and the ^{16}O atom has a mass of 2.6560×10^{-23} g. As we noted in Section 2.3, it is convenient to use the *atomic mass unit* when dealing with these extremely small masses:

$$1\ \text{amu} = 1.66054 \times 10^{-24}\ \text{g} \quad \text{and} \quad 1\ \text{g} = 6.02214 \times 10^{23}\ \text{amu}$$

The atomic mass unit is presently defined by assigning a mass of exactly 12 amu to an individual atom of the ^{12}C isotope of carbon. In these units, an ^1H atom has a mass of 1.0078 amu and an ^{16}O atom has a mass of 15.9949 amu.

Atomic Weight

Most elements occur in nature as mixtures of isotopes. We can determine the *average atomic mass* of an element, usually called the element's **atomic weight**, by summing (indicated by the uppercase Greek sigma, Σ) over the masses of its isotopes multiplied by their relative abundances:

$$\text{Atomic weight} = \sum_{\substack{\text{over all}\\ \text{isotopes of}\\ \text{the element}}} [(\text{fractional isotope abundance}) \times (\text{isotope mass})] \qquad [2.1]$$

Naturally occurring carbon, for example, is composed of 98.93% ^{12}C and 1.07% ^{13}C. The masses of these isotopes are 12 amu (exactly) and 13.00335 amu, respectively, making the atomic weight of carbon

$$(0.9893)(12\ \text{amu}) + (0.0107)(13.00335\ \text{amu}) = 12.01\ \text{amu}$$

The atomic weights of the elements are listed in both the periodic table and the table of elements on the front inside cover of this text.

Sample Exercise 2.4

Calculating the Atomic Weight of an Element from Isotopic Abundances

Naturally occurring chlorine is 75.75% ^{35}Cl (atomic mass 34.969 amu) and 24.22% ^{37}Cl (atomic mass 36.966 amu). Calculate the atomic weight of chlorine.

SOLUTION

We can calculate the atomic weight by multiplying the abundance of each isotope by its mass and summing these products. Because 75.78% = 0.7578 and 24.22% = 0.2422, we have

$$\begin{aligned}\text{Atomic wight} &= (0.7578)(34.969\text{ amu}) + (0.2422)(36.966\text{ amu})\\ &= 26.50\text{ amu} + 8.953\text{ amu}\\ &= 35.45\text{ amu}\end{aligned}$$

This answer makes sense: The atomic weight, which is actually the average atomic mass, is between the masses of the two isotopes and is closer to the value of ^{35}Cl, the more abundant isotope.

Practice Exercise

Three isotopes of silicon occur in nature: ^{28}Si (92.23%), atomic mass 27.97693 amu; ^{29}Si (4.68%), atomic mass 28.97649 amu; and ^{30}Si (3.09%), atomic mass 29.97377 amu. Calculate the atomic weight of silicon.

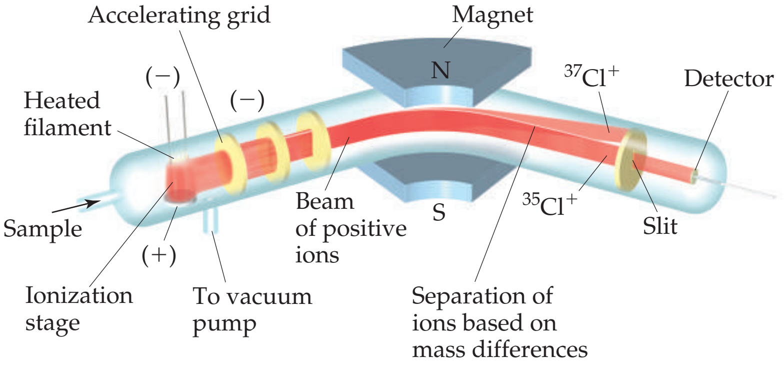
A CLOSER LOOK The Mass Spectrometer

The most accurate means for determining atomic weights is provided by the **mass spectrometer** (Figure 2.11). There are various designs of mass spectrometers, but they all operate on similar principles. The first step is to get atoms or molecules into the gas phase. Sometimes the sample to be analyzed is already a gas, whereas in other cases heating, application of an electric field, or a pulse of laser light may be needed to create gas-phase atoms or molecules. Next, the gas-phase species must be converted to positively charged particles called *ions*. There are many approaches to creating ions, including bombardment with beams of high-energy electrons or chemical reactions with other gas-phase molecules. Once gas-phase ions have been produced, they are accelerated toward a negatively charged grid. After the ions pass through the grid, they encounter two slits that allow only a narrow beam of ions to pass. This beam then passes between the poles of a magnet, which deflects the ions into a curved path. For ions with the same charge, the extent of deflection depends on mass—the more massive the ion, the less the deflection. The ions are thereby separated according to their masses. By changing the strength of the magnetic field or the accelerating voltage on the grid, ions of various masses can be selected to enter the detector.

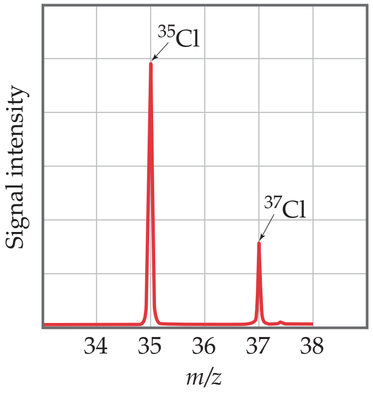
A graph of the intensity of the detector signal versus ion atomic mass is called a *mass spectrum* (Figure 2.12). Analysis of a mass spectrum gives both the masses of the ions reaching the detector and their relative abundances, which are obtained from the signal intensities. Knowing the atomic mass and abundance of each isotope allows us to calculate the atomic weight of an element, as shown in Sample Exercise 2.4.

Mass spectrometers are used extensively today to identify chemical compounds and analyze mixtures of substances. Any molecule that loses electrons can fall apart, forming an array of positively charged fragments. The mass spectrometer measures the masses of these fragments, producing a chemical "fingerprint" of the molecule and providing clues about how the atoms were connected in the original molecule. Thus, a chemist might use this technique to determine the molecular structure of a newly synthesized compound, to analyze proteins in the human genome, or to identify a pollutant in the environment.

Related Exercises: 2.37, 2.38, 2.40, 2.94, 2.100, 2.101



▲ **Figure 2.11 How a mass spectrometer works.** The example here is for chlorine. Cl atoms are first ionized to form Cl^+ ions, the ions are then accelerated with an electric field, and finally their path is directed by a magnetic field. The paths of the ions of the two Cl isotopes diverge as they pass through the magnetic field. Nearly all of the air in the instrument must be removed with the vacuum pump before the experiment starts, so the paths of the ions are uninterrupted.



▲ **Figure 2.12 Mass spectrum of atomic chlorine.** The fractional abundances of the isotopes ^{35}Cl and ^{37}Cl are indicated by the relative signal intensities of the beams of Cl^+ reaching the detector of the mass spectrometer. Technically, the mass spectrometer measures the mass/charge ratio of ions; but most ions are only singly charged in the experiment, so you can read the horizontal axis as the atomic mass of the isotope in units of amu.

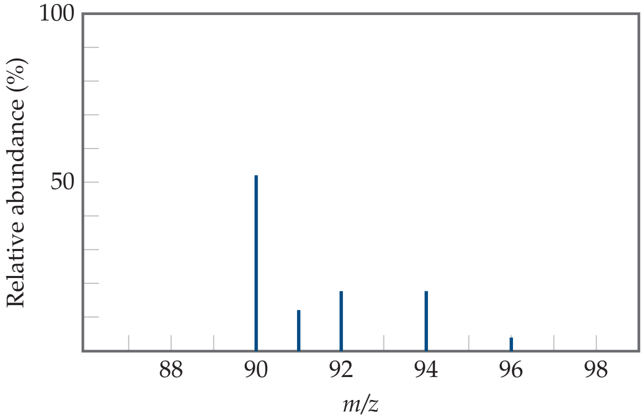
Self-Assessment Exercises

SAE 2.10 Boron has two naturally occurring isotopes: ^{10}B, with a mass of 10.01 amu, and ^{11}B, with a mass of 11.01 amu. Use the average atomic weight of boron from the periodic table to determine the abundance of the ^{11}B isotope. (**a**) 3.8% (**b**) 20.0% (**c**) 80.0% (**d**) 81.0%

SAE 2.11 A new element, Brownium, is discovered in a parallel universe. Brownium's average atomic weight is 28.00 amu; it has 14 protons in its nucleus; and its two isotopes have either 13 or 16 neutrons in the nucleus. What is the ratio of the 27-amu isotope to the 30-amu isotope? (**a**) 1:1 (**b**) 1:3 (**c**) 2:3 (**d**) 2:1 (**e**) Not enough information is given to answer this question.

SAE 2.12 Which statement is true about mass spectrometry? (**a**) The data from a mass spectrometer tells you the charges of ions. (**b**) Neutral atoms can be detected in the mass spectrometer. (**c**) The heavier a charged particle is, the more it will be deflected by a magnetic field. (**d**) Different isotopes of an element will be deflected by different amounts in a mass spectrometer. (**e**) More than one of statements (a), (b), (c), (d) are true.

SAE 2.13 Use the following data from a mass spectrometer of an unknown element to determine the probable identity of the element. (**a**) Th (**b**) Pa (**c**) Zr (**d**) Nb



2.5 | The Periodic Table

As the list of known elements expanded during the early 1800s, attempts were made to find patterns in chemical behavior. These efforts culminated in the development of the periodic table in 1869. The periodic table plays a major role in later chapters of this text, but it is so important and useful that you should become acquainted with it now. In fact, *the periodic table is the most significant tool that chemists use for organizing and remembering chemical facts*.

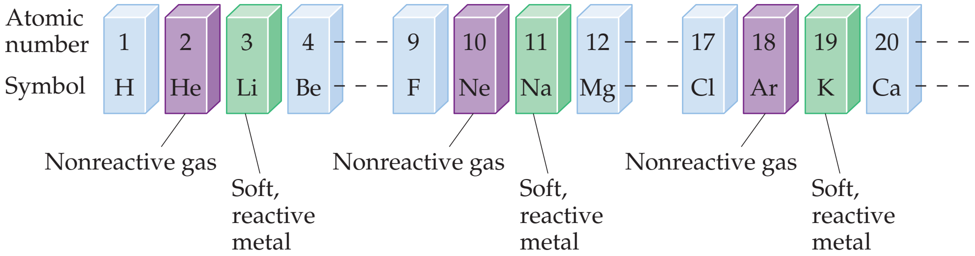
Many elements show strong similarities to one another. The elements lithium (Li), sodium (Na), and potassium (K) are all soft, very reactive metals that produce heat and sparks upon mixing with water. The elements helium (He), neon (Ne), and argon (Ar) are all nonreactive gases. If the elements are arranged in order of increasing atomic number, their chemical and physical properties show a repeating, or *periodic*, pattern. For example, each of the soft, reactive metals—lithium, sodium, and potassium—comes immediately after one of the nonreactive gases—helium, neon, and argon, respectively—as shown in **Figure 2.13**.

Learning Objectives

When you finish Section 2.5, you should be able to:

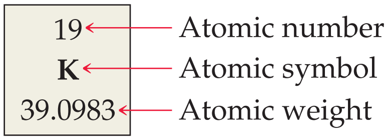
- ▶ Infer an element's general properties from its location in the periodic table.
- ▶ Describe the overall structure of the periodic table of the elements in terms of periods and groups.

Go Figure If F is a reactive nonmetal, which other element or elements shown here are likely to be reactive nonmetals?



▲ **Figure 2.13 Arranging elements by atomic number reveals a periodic pattern of properties.** This pattern is the basis of the periodic table.

The arrangement of elements in order of increasing atomic number, with elements having similar properties placed in vertical columns, is known as the **periodic table** (Figure 2.14). The table shows the atomic number and atomic symbol for each element, and the atomic weight is often given as well, as in this typical entry for potassium:



19
K
39.0983
Atomic number
Atomic symbol
Atomic weight

You might notice slight variations in periodic tables from one book to another or between those in the lecture hall and in the text. These are simply matters of style; there are no fundamental differences.

The horizontal rows of the periodic table are called **periods**. The first period consists of only two elements, hydrogen (H) and helium (He). The second and third periods consist of eight elements each. The fourth and fifth periods contain 18 elements. The sixth and seventh periods have 32 elements each, but in order to fit on a page, 14 of the elements from each period (atomic numbers 57–70 and 89–102) appear at the bottom of the table.

The vertical columns are called **groups**. The way in which the groups are labeled is somewhat arbitrary. Three labeling schemes are in common use, two of which are shown in Figure 2.14.

- The top set of labels, which have A and B designations, is widely used in North America. Roman numerals, rather than Arabic ones, are often employed in this scheme. Group 7A, for example, is often labeled VIIA.

Go Figure Where are sodium and potassium in the periodic table? Do they belong to the same period? Do they belong to the same group?

▲ **Figure 2.14 The periodic table of the elements.**

- Europeans use a similar convention that assigns the A and B labels differently.
- In an effort to eliminate confusion, the International Union of Pure and Applied Chemistry (IUPAC) introduced a convention that numbers the groups from 1 through 18 with no A or B designations, as shown in Figure 2.14.

We use the traditional North American convention with Arabic numerals and the letters A and B.

Elements in a group often exhibit similarities in physical and chemical properties. For example, the "coinage metals"—copper (Cu), silver (Ag), and gold (Au)—belong to group 1B. These elements are less reactive than most metals, which is why they have been traditionally used throughout the world to make coins. Many other groups in the periodic table also have names, listed in **Table 2.3**.

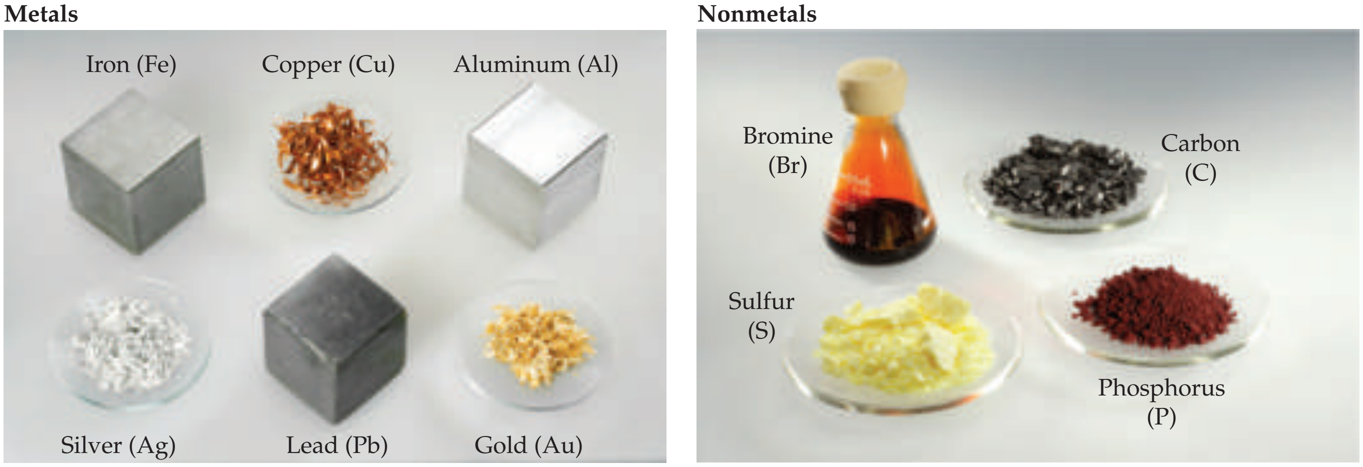
TABLE 2.3 Names of Some Groups in the Periodic Table

Group	Name	Elements
1A	Alkali metals	Li, Na, K, Rb, Cs, Fr
2A	Alkaline earth metals	Be, Mg, Ca, Sr, Ba, Ra
6A	Chalcogens	O, S, Se, Te, Po
7A	Halogens	F, Cl, Br, I, At
8A	Noble gases	He, Ne, Ar, Kr, Xe, Rn

We explain in Chapters 6 and 7 that elements in a group have similar properties because they have the same arrangement of electrons at the periphery of their atoms. However, we need not wait until then to make good use of the periodic table; after all, the chemists who developed the table knew nothing about electrons! We can use the table, as they intended, to correlate behaviors of elements and to help us remember many facts.

The color code of Figure 2.14 shows that, except for hydrogen, all the elements on the left and in the middle of the table are **metallic elements**, or **metals**. All the metallic elements share characteristic properties, such as luster and high electrical and heat conductivity, and all of them except mercury (Hg) are solid at room temperature.* The metals are separated from the **nonmetallic elements**, or **nonmetals**, by a stepped line that runs from boron (B) to astatine (At). (Note that hydrogen, although on the left side of the table, is a nonmetal.) At room temperature and pressure, some of the nonmetals are gaseous, some are solid, and one is liquid. Nonmetals generally differ from metals in appearance (**Figure 2.15**) and in other physical properties. Many of

Go Figure Name two ways in which the metals shown here differ in general appearance from the nonmetals.



▲ **Figure 2.15** Examples of metals and nonmetals.

---

*All metals become liquids if heated sufficiently. Hg simply has the lowest melting point of any metallic element. Although sodium (Na), potassium (K), rubidium (Rb), cesium (Cs), and gallium (Ga) are solids at room temperature, they all melt at temperatures below 100 °C.

the elements that lie along the line that separates metals from nonmetals have properties that fall between those of metals and nonmetals. These elements are often referred to as **metalloids**.

Sample Exercise 2.5

Using the Periodic Table

Which two of these elements would you expect to show the greatest similarity in chemical and physical properties: B, Ca, F, He, Mg, P?

SOLUTION

Elements in the same group of the periodic table are most likely to exhibit similar properties. We therefore expect Ca and Mg to be most alike because they are in the same group (2A, the alkaline earth metals).

Practice Exercise

Locate Na (sodium) and Br (bromine) in the periodic table. Give the atomic number of each and classify each as metal, metalloid, or nonmetal.

Self-Assessment Exercises

SAE 2.14 Find manganese on the periodic table. Which of the following statements is true about this element? (**a**) Manganese has atomic number 12. (**b**) Manganese is in period 7. (**c**) Manganese is an alkaline earth metal. (**d**) None of statements (a), (b), (c) is true.

SAE 2.15 Which of the following statements is or are true?

(**i**) Elements in the same period of the periodic table are expected to have chemically similar properties.

(**ii**) Elements in the same group of the periodic table are expected to have chemically similar properties.

(**iii**) Elements in the same period of the periodic table are arranged in order of increasing atomic number.

(**a**) i only (**b**) ii only (**c**) iii only(**d**) i and iii (**e**) ii and iii

2.6 | Molecules and Molecular Compounds

Learning Objectives

When you finish Section 2.6, you should be able to:

- Write the molecular formula of a compound given a picture of its structure.
- Differentiate between the molecular and empirical formulas of a molecular compound.

Even though the atom is the smallest representative sample of an element, only the noble-gas elements are normally found in nature as isolated atoms. Most matter is composed of molecules or ions. We examine molecules here in Section 2.6 and ions in Section 2.7.

Molecules and Chemical Formulas

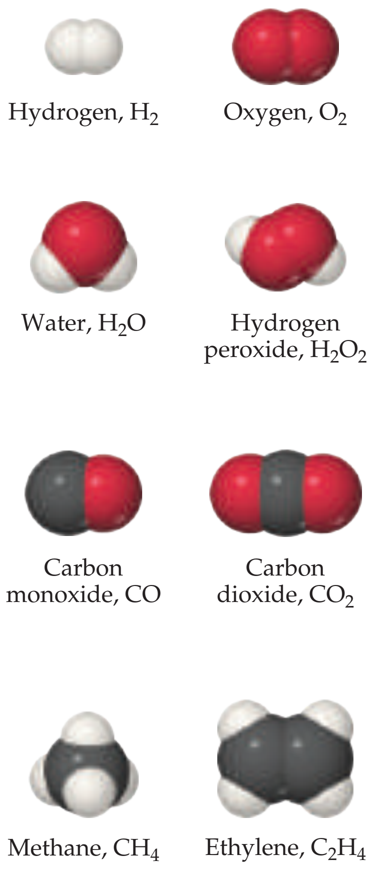
Several elements are found in nature in molecular form—two or more of the same type of atom bound together. For example, most of the oxygen in air consists of molecules that contain two oxygen atoms. As we saw in Section 1.2, we represent this molecular oxygen by the **chemical formula** O_2 (read "oh two"). The subscript tells us that two oxygen atoms are present in each molecule. A molecule made up of two atoms is called a **diatomic molecule**.

Oxygen also exists in another molecular form known as *ozone*. Molecules of ozone consist of three oxygen atoms, making the chemical formula O_3. Even though "normal" oxygen (O_2) and ozone (O_3) are both composed only of oxygen atoms, they exhibit very different chemical and physical properties. For example, O_2 is essential for life, but O_3 is toxic; O_2 is odorless, whereas O_3 has a sharp, pungent smell.

The elements that normally occur as diatomic molecules are hydrogen, oxygen, nitrogen, and the halogens ($H_2, O_2, N_2, F_2, Cl_2, Br_2$, and I_2). Except for hydrogen, these diatomic elements are clustered on the right side of the periodic table.

Compounds composed of molecules that contain more than one type of atom are called **molecular compounds** or **molecular substances**. A molecule of the compound methane, for example, consists of one carbon atom and four hydrogen atoms and is therefore represented by the chemical formula CH_4. Lack of a subscript on the C indicates one atom of C per methane molecule. Several common molecules of both elements and compounds are shown in **Figure 2.16**. Notice how the composition of each substance is given by its chemical formula. Notice also that these substances are composed only of nonmetallic elements.

Most of the molecular substances we discuss contain only nonmetals.



▲ **Figure 2.16 Molecular models.** Notice how the chemical formulas of these simple molecules correspond to their compositions.

Molecular and Empirical Formulas

Chemical formulas that indicate the actual numbers of atoms in a molecule, such as those in Figure 2.16, are called **molecular formulas**. Chemical formulas that give only the relative number of atoms of each type in a molecule are called **empirical formulas**. The subscripts in an empirical formula are always the smallest possible whole-number ratios. The molecular formula for hydrogen peroxide is H_2O_2, for example, whereas its empirical formula is HO. The molecular formula for ethylene is C_2H_4, so its empirical formula is CH_2. For many substances, the molecular formula and the empirical formula are identical, as in the case of water, H_2O.

Whenever we know the molecular formula of a compound, we can determine its empirical formula. The converse is not true, however. If we know the empirical formula of a substance, we cannot determine its molecular formula unless we have more information. Why, then, do chemists bother with empirical formulas? As we explain in Chapter 3, common experimental methods of analyzing substances lead to the empirical formula only. For example, if you decomposed hydrogen peroxide H_2O_2 into its elements and weighed them, you could determine that there were equal numbers of hydrogen and oxygen atoms, but you would not know if the molecular formula was HO, H_2O_2, H_3O_3, or the like. Once the empirical formula is known, additional experiments can give the information needed to convert the empirical formula to the molecular one. In addition, many substances do not exist as isolated molecules; major examples are the ionic compounds that are discussed later in this chapter. For these substances, we must rely on empirical formulas.

Sample Exercise 2.6
Relating Empirical and Molecular Formulas

Write the empirical formulas for (**a**) glucose, a substance also known as either blood sugar or dextrose—molecular formula $C_6H_{12}O_6$; and (**b**) nitrous oxide, a substance used as an anesthetic and commonly called laughing gas—molecular formula N_2O.

SOLUTION

(**a**) The subscripts of an empirical formula are the smallest whole-number ratios. The smallest ratios are obtained by dividing each subscript by the largest common factor, in this case 6. The resultant empirical formula for glucose is CH_2O.

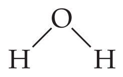
(**b**) Because the subscripts in N_2O are already the lowest integral numbers, the empirical formula for nitrous oxide is the same as its molecular formula, N_2O.

▶ Practice Exercise

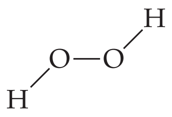
Give the empirical formula for *decaborane*, whose molecular formula is $B_{10}H_{14}$.

Picturing Molecules

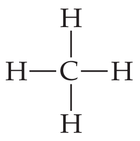
The molecular formula of a substance does not show how its atoms are joined together. A **structural formula** is needed to convey that information, as in the following examples:



Water



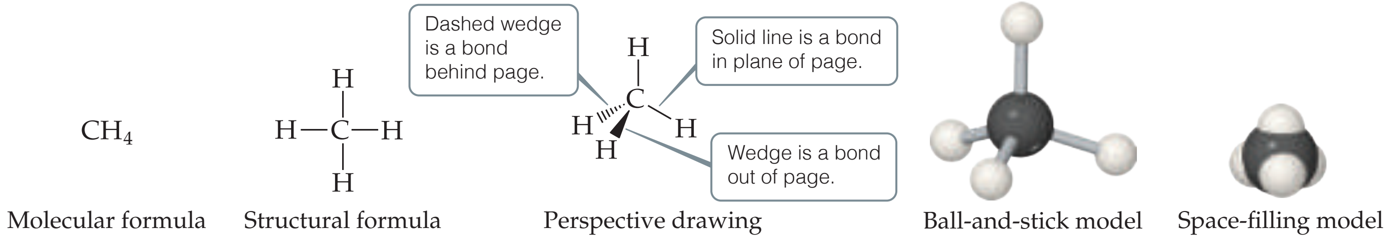
Hydrogen peroxide



Methane

Go Figure

Which molecular model, the ball-and-stick or the space-filling, more effectively shows the angles between bonds around a central atom?



▲ **Figure 2.17** **Different representations of the methane (CH_4) molecule.**

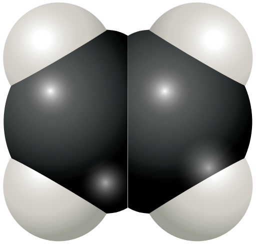
The atoms are represented by their chemical symbols, and lines are used to represent the bonds that hold the atoms together. The observation that the angles between the bonds are not all the same indicates something about the detailed geometric structure of molecules, as we now discuss.

A structural formula does not typically depict the actual geometry of the molecule—that is, the actual angles at which atoms are joined; for that depiction, more sophisticated representations are needed (**Figure 2.17**).

- **Perspective drawings** use wedges and dashed wedges to depict bonds that are not in the plane of the paper. This gives a crude sense of the three-dimensional shape of a molecule. This is the most common drawing that chemists use. For a molecule in which all the atoms lie in one plane, such as H_2O, we do not need to use wedges and dashed wedges.
- **Ball-and-stick models** show atoms as spheres and bonds as sticks. This type of model has the advantage of accurately representing the angles at which the atoms are attached to one another in a molecule and the relative lengths of the bonds that hold the atoms together (Figure 2.17). Sometimes the chemical symbols of the elements are superimposed on the balls, but often the atoms are identified simply by color.
- **Space-filling models** depict what a molecule would look like if the atoms were scaled up in size (Figure 2.17). These models show the relative sizes of the atoms, but the angles between atoms, which help define their molecular geometry, are often more difficult to see than in ball-and-stick models. Because space-filling models give a good representation of the true size of a molecule, they are useful for picturing how two molecules might fit together or pack in the solid state. As with ball-and-stick models, the identities of the atoms are typically indicated by color.

Self-Assessment Exercises

SAE 2.16 What is the molecular formula of this compound?



(**a**) CH_4 (**b**) C_2H_4 (**c**) C_2O_4 (**d**) O_2H_4

SAE 2.17 Oleic acid is a common fatty acid in nature. A shorthand way to write its chemical structure is $CH_3(CH_2)_7CHCH(CH_2)_7COOH$. What is oleic acid's empirical formula? (**a**) C_3H_5O (**b**) $C_6H_{10}O_2$ (**c**) $C_9H_{17}O$ (**d**) $C_{18}H_{34}O_2$

SAE 2.18 Acetylene's molecular formula is C_2H_2; benzene's is C_6H_6. Which statement about these two molecules is *false*? (**a**) Both acetylene and benzene have the same empirical formula. (**b**) The ratio of C/H masses in both benzene and acetylene is the same. (**c**) The number of carbon atoms in one benzene molecule is the same as the number of carbon atoms in one acetylene molecule. (**d**) Benzene is a bigger molecule than acetylene.

2.7 | Ions and Ionic Compounds

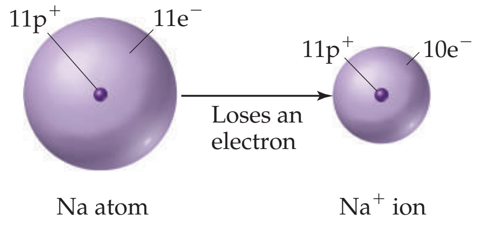
If electrons are removed from or added to an atom, a charged particle called an **ion** is formed. An ion with a positive charge is a **cation** (pronounced CAT-ion), whereas a negatively charged ion is an **anion** (AN-ion).

To see how ions form, consider the sodium atom, which has 11 protons and 11 electrons. This atom easily loses one electron. The resulting cation has 11 protons and 10 electrons, which means it has a net charge of 1+.

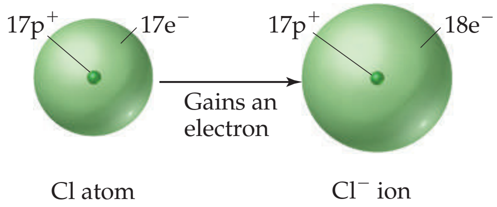
Learning Objectives

When you finish Section 2.7, you should be able to:

- Write chemical symbols for ions and predict the most common ionic charges for elements toward the left and right sides of the periodic table.
- Predict the empirical formula of an ionic compound given its constituent elements.
- Distinguish between molecular and ionic compounds based on the chemical formula of the compound.



The net charge on an ion is represented by a superscript. The superscripts +, 2+, and 3+, for instance, mean a net charge resulting from the *loss* of one, two, and three electrons, respectively. The superscripts −, 2−, and 3− represent net charges resulting from the *gain* of one, two, and three electrons, respectively. Chlorine, with 17 protons and 17 electrons, for example, can gain an electron in chemical reactions, producing the Cl^- ion:



In general, metal atoms tend to lose electrons to form cations, whereas nonmetal atoms tend to gain electrons to form anions. Thus, ionic compounds tend to be composed of both metal cations and nonmetal anions, as in NaCl.

Sample Exercise 2.7

Writing Chemical Symbols for Ions

Give the chemical symbol, including superscript indicating mass number, for (**a**) the ion with 22 protons, 26 neutrons, and 19 electrons; and (**b**) the ion of sulfur that has 16 neutrons and 18 electrons.

SOLUTION

(**a**) The number of protons is the atomic number of the element. According to the periodic table or a list of elements, the element with atomic number 22 is titanium (Ti). The mass number (protons plus neutrons) of this isotope of titanium is $22 + 26 = 48$. Because the ion has three more protons than electrons, it has a net charge of 3+ and is designated $^{48}Ti^{3+}$.

(**b**) The periodic table shows that sulfur (S) has an atomic number of 16. Thus, each atom or ion of sulfur contains 16 protons. We are told that the ion also has 16 neutrons, meaning the mass number is $16 + 16 = 32$. Because the ion has 16 protons and 18 electrons, its net charge is 2− and the ion symbol is $^{32}S^{2-}$.

In general, we focus on the net charges of ions and ignore their mass numbers unless the circumstances dictate that we specify a certain isotope.

Practice Exercise

How many protons, neutrons, and electrons does the $^{79}Se^{2-}$ ion possess?

In addition to simple ions such as Na^+ and Cl^-, there are **polyatomic ions**, such as NH_4^+ (ammonium ion) and SO_4^{2-} (sulfate ion), which consist of atoms joined as in a molecule, but carrying a net positive or negative charge. Polyatomic ions are discussed in Section 2.8.

It is important to realize that the chemical properties of ions are very different from the chemical properties of the atoms from which the ions are derived. The addition or removal of one or more electrons produces a charged species with behavior very different from that of its associated atom or group of atoms. For example, sodium metal reacts violently with water, but an ionic compound containing sodium ions, such as NaCl, does not.

Predicting Ionic Charges

The noble gases (group 8A—see Table 2.3) are chemically nonreactive elements that form very few compounds. Many atoms gain or lose electrons to end up with the same number of electrons as the noble gas closest to them in the periodic table. We might deduce that atoms tend to acquire the electron arrangements of the noble gases because these electron arrangements are very stable. Nearby elements can obtain these same stable arrangements by losing or gaining electrons. For example, the loss of one electron from an atom of sodium leaves it with the same number of electrons as in a neon atom (10). Similarly, when chlorine gains an electron, it ends up with 18, the same number of electrons as in argon. This simple observation will be helpful for now to account for the formation of ions. A deeper explanation awaits us in Chapter 8, where we discuss chemical bonding.

Sample Exercise 2.8

Predicting Ionic Charge

Predict the charge expected for the most stable ion of barium and the most stable ion of oxygen.

SOLUTION

We will assume that barium and oxygen form ions that have the same number of electrons as the nearest noble-gas atom. From the periodic table, we see that barium has atomic number 56. The nearest noble gas is xenon, atomic number 54. Barium can attain a stable arrangement of 54 electrons by losing two electrons, forming the Ba^{2+} cation.

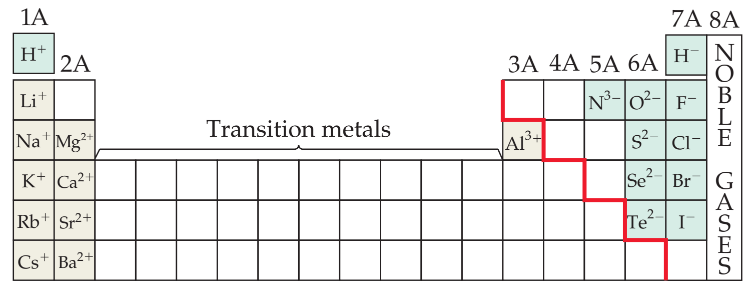
Oxygen has atomic number 8. The nearest noble gas is neon, atomic number 10. Oxygen can attain this stable electron arrangement by gaining two electrons, forming the O^{2-} anion.

▶ Practice Exercise

Predict the charge expected for the most stable ion of (**a**) aluminum and (**b**) fluorine.

The periodic table is useful for remembering ionic charges, especially those of elements on the left and right sides of the table. As **Figure 2.18** shows, the charges of these ions relate in a simple way to their positions in the table: The group 1A elements (alkali metals) form 1+ ions, the group 2A elements (alkaline earth metals) form 2+ ions, the group 7A elements (halogens) form 1− ions, and the group 6A elements form 2− ions. Many of the other groups do not lend themselves to such simple rules.

Go Figure Which element can form both a cation and an anion?

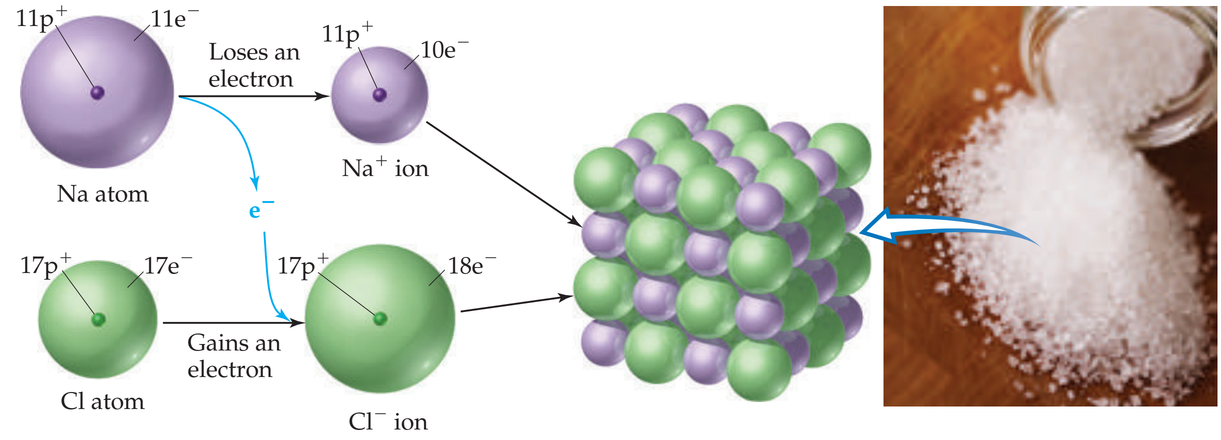


▲ **Figure 2.18 Predictable charges of some common ions.** Notice that the red stepped line that divides metals from nonmetals also separates cations from anions. Hydrogen forms both 1+ and 1− ions. The H anion is shown in group7A, but that is just for convenience to show the common charges and reactivity; an element only appears once in the full periodic table.

Ionic Compounds

A great deal of chemical activity involves the transfer of electrons from one substance to another. **Figure 2.19** shows that when elemental sodium is allowed to react with elemental chlorine, an electron transfers from a sodium atom to a chlorine atom, forming a Na^+ ion and a Cl^- ions. Because objects of opposite charges attract, the Na^+ and the Cl^- ions bind together to form the compound sodium chloride (NaCl). Sodium chloride, which we know better as common table salt, is an example of an **ionic compound**, a compound made up of cations and anions.

Go Figure Should there be equal or unequal numbers of sodium cations and chloride anions in the space-filling model?



▲ **Figure 2.19 Formation of an ionic compound.** The transfer of an electron from a sodium atom to a chlorine atom leads to the formation of a Na^+ ion and a Cl^- ion. These ions are arranged in a lattice in solid sodium chloride, NaCl. This representation of solid NaCl is a space-filling one that shows the relative sizes of the ions.

We can often tell whether a compound is ionic (consisting of ions) or molecular (consisting of molecules) from its composition. As a general rule, cations are metal ions and anions are nonmetal ions. Consequently,

> *Ionic compounds are generally combinations of metals and nonmetals, as in NaCl.*

Sample Exercise 2.9

Identifying Ionic and Molecular Compounds

Which of these compounds would you expect to be ionic: N_2O, Na_2O, $CaCl_2$, SF_4?

SOLUTION

We predict that Na_2O and $CaCl_2$ are ionic compounds because they are composed of a metal combined with a nonmetal. We predict (correctly) that N_2O and SF_4 are molecular compounds because they are composed entirely of nonmetals.

▶ Practice Exercise

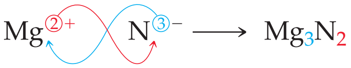
Explain why each of the following statements is probably true:

(a) Every compound of Rb with a nonmetal is ionic in character.
(b) Every compound of nitrogen with a halogen element is a molecular compound.
(c) The compound $MgKr_2$ does not exist.
(d) Na and K are very similar in the compounds they form with nonmetals.
(e) If contained in an ionic compound, calcium (Ca) will be in the form of the doubly charged ion, Ca^{2+}.

The ions in ionic compounds are arranged in three-dimensional structures, as Figure 2.19 shows for NaCl. Because there is no discrete “molecule” of NaCl, we are able to write only an empirical formula for this substance. This is true for most other ionic compounds.

We can write the empirical formula for an ionic compound if we know the charges of the ions. Because chemical compounds are always electrically neutral, the ions in an ionic compound always occur in such a ratio that the total positive charge equals the total negative charge. Thus, there is one Na^+ to one Cl^- in NaCl, one Ba^{2+} to two Cl^- in $BaCl_2$, and so forth.

As you consider these and other examples, you will see that if the charges on the cation and anion are equal, the subscript on each ion is 1. If the charges are unequal, the charge on one ion (without its sign) will become the subscript on the other ion. For example, the ionic compound formed from Mg (which forms Mg^{2+} ions) and N (which forms N^{3-} ions) is Mg_3N_2:

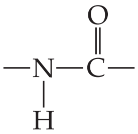


$$Mg^{②+} \quad N^{③-} \longrightarrow Mg_3N_2$$

There is one caveat when you are using this approach. Remember that the empirical formula should be the smallest possible whole-number ratio of the two elements. So the empirical formula for the ionic compound formed between Ti^{4+} and O^{2-} is TiO_2 rather than Ti_2O_4.

CHEMISTRY AND LIFE **Elements Required by Living Organisms**

The elements essential to life are highlighted in color in **Figure 2.20**. More than 97% of the mass of most organisms is made up of just six of these elements—oxygen, carbon, hydrogen, nitrogen, phosphorus, and sulfur. Water is the most common compound in living organisms, accounting for at least 70% of the mass of most cells. In the solid components of cells, carbon is the most prevalent element by mass. Carbon atoms are found in a vast variety of organic molecules, bonded either to other carbon atoms or to atoms of other elements. Nearly all proteins, for example, contain the carbon-based group



which occurs repeatedly in the molecules.

In addition, 23 other elements have been found in various living organisms. Five are ions required by all organisms: Ca^{2+}, Cl^-, Mg^{2+}, K^+, and Na^+. Calcium ions, for example, are necessary for the formation of bone and the transmission of nervous system signals. Many other elements are needed in only very small quantities and consequently are called *trace* elements. For example, trace quantities of copper are required in the diet of humans to aid in the synthesis of hemoglobin.

Sample Exercise 2.10
Using Ionic Charge to Write Empirical Formulas for Ionic Compounds

Write the empirical formula of the compound formed by (**a**) Al^{3+} and Cl^- ions, (**b**) Al^{3+} and O^{2-} ions, (**c**) Mg^{2+}, and NO_3^- ions.

SOLUTION

(**a**) Three Cl^- ions are required to balance the charge of one Al^{3+} ion, making the empirical formula $AlCl_3$.

(**b**) Two Al^{3+} ions are required to balance the charge of three O^{2-} ions. A 2:3 ratio is needed to balance the total positive charge of 6+ and the total negative charge of 6−. The empirical formula is Al_2O_3.

(**c**) Two NO_3^- ions are needed to balance the charge of one Mg^{2+}, yielding $Mg(NO_3)_2$. The formula for the polyatomic ion, NO_3^-, must be enclosed in parentheses so that it is clear that the subscript 2 applies to all the atoms of that ion.

▶ **Practice Exercise**

Write the empirical formula for the compound formed by (**a**) Na^+ and PO_4^{3-}, (**b**) Zn^{2+} and SO_4^{2-}, (**c**) Fe^{3+} and CO_3^{2-}.

Self-Assessment Exercises

SAE 2.19 Which pair of element and most common ionic charge is correct? (**a**) F/1+ (**b**) Na/1− (**c**) C/6+ (**d**) Ba/2+

SAE 2.20 Which of the following statements is *false*? (**a**) Elements tend to lose or gain electrons in order to have the same number of electrons as the nearest noble gas. (**b**) Nonmetals tend to form anions. (**c**) The group 7A elements tend for form 1+ ions. (**d**) Metals tend to form cations. (**e**) Ionic compounds generally contain both a metal and a nonmetal.

SAE 2.21 Predict the empirical formula of strontium chloride. (**a**) SrCl (**b**) $SrCl_2$ (**c**) $SrCl_3$ (**d**) SCl (**e**) SCl_2

SAE 2.22 Which pair of compounds/types is correct? (**a**) SO_2, ionic compound (**b**) MnO_2, molecular compound (**c**) TiO_2, molecular compound (**d**) CF_4, ionic compound (**e**) NaH, ionic compound

2.8 | Naming Inorganic Compounds

Learning Objectives

When you finish Section 2.8, you should be able to:

- Interconvert between the name and empirical formula of an ionic compound.
- Interconvert between the name and chemical formula of an inorganic acid.
- Interconvert between the name and chemical formula of binary molecular compounds.

The names and chemical formulas of compounds are essential vocabulary in chemistry. The system used in naming substances is called **chemical nomenclature**, from the Latin words *nomen* (name) and *calare* (to call).

There are more than 163 million known chemical substances. Naming them all would be a hopelessly complicated task if each had a name independent of all others. Many important substances that have been known for a long time, such as water (H_2O) and ammonia (NH_3), do have traditional names (called *common names*). For most substances, however, we rely on a set of rules that leads to an informative and unique name that conveys the composition of the substance.

The rules for chemical nomenclature are based on the division of substances into categories. The major division is between organic and inorganic compounds. *Organic compounds* contain carbon and hydrogen, often in combination with oxygen, nitrogen, or other elements. All others are *inorganic compounds*. Early chemists associated organic compounds with plants and animals and inorganic compounds with the nonliving portion of our world. Although this distinction is no longer pertinent, the classification between organic and inorganic compounds continues to be useful. In this section, we consider the basic rules for naming three categories of inorganic compounds: ionic compounds, acids, and molecular compounds.

Names and Formulas of Ionic Compounds

Recall from Section 2.7 that ionic compounds usually consist of metal cations combined with nonmetal anions.

1. **Cations**

   a. *Cations formed from metal atoms have the same name as the metal:*

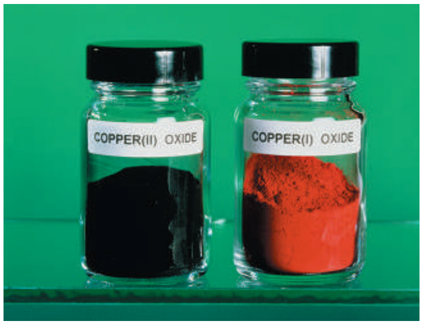
Na^+	sodium ion	Zn^{2+}	zinc ion	Al^{3+}	aluminum ion

   b. *If a metal can form cations with different charges, the positive charge is indicated by a Roman numeral in parentheses following the name of the metal:*

Fe^{2+}	iron(II) ion	Cu^+	copper(I) ion
Fe^{3+}	iron(III) ion	Cu^{2+}	copper(II) ion

Ions of the same element that have different charges have different chemical and physical properties, such as color (Figure 2.21).

Most metals that form cations with different charges are transition metals, elements that occur in the middle of the periodic table, from group 3B to group 2B (as indicated on the periodic table on the front inside cover of this book). The metals that form only one cation (only one possible charge) are those of group 1A and group 2A, as well as Al^{3+} (group 3A). The transition-metal ions Ag^+



▲ **Figure 2.21 Different ions of the same element have different properties.** Both substances shown are copper oxides. One is cuprous oxide, Cu_2O; the other is cupric oxide, CuO.

(group 1B), Zn^{2+} (group 2B), and Cd^{2+} (group 2B) also form only one cation in most situations. Charges are not normally expressed when naming these ions. However, if there is any doubt in your mind whether a metal forms more than one cation, use a Roman numeral to indicate the charge. It is never wrong to do so, even though it may be unnecessary.

An older method still widely used for distinguishing between differently charged ions of a metal uses the suffixes *-ous* and *-ic* added to the root of the element's Latin name:

Fe^{2+}	ferrous ion	Cu^{+}	cuprous ion
Fe^{3+}	ferric ion	Cu^{2+}	cupric ion

Although we only rarely use these older names in this text, you might encounter them elsewhere.

c. *Cations formed from molecules composed of nonmetal atoms have names that end in* -ium:

$NH_4{}^{+}$	ammonium ion	H_3O^{+}	hydronium ion

These two ions are the only ions of this kind that we encounter frequently in the text.

The names and formulas of some common cations are listed in **Table 2.4** and on the back inside cover of the text. Those on the left side in Table 2.4 are the monatomic ions that do not have more than one possible charge. Those on the right side are either polyatomic cations or cations with more than one possible charge. The $Hg_2{}^{2+}$ ion is unusual because, even though it is a metal ion, it is not monatomic. It is called the mercury(I) ion because it can be thought of as two Hg^{+} ions bound together. The cations that you will encounter most frequently in this text are shown in boldface. You should learn these cations first.

TABLE 2.4 Common Cations[a]

Charge	Formula	Name	Formula	Name
1+	**H^{+}**	**hydrogen ion**	**$NH_4{}^{+}$**	**ammonium ion**
	Li^{+}	lithium ion	Cu^{+}	copper(I) or cuprous ion
	Na^{+}	**sodium ion**		
	K^{+}	**potassium ion**		
	Cs^{+}	cesium ion		
	Ag^{+}	**silver ion**		
2+	**Mg^{2+}**	**magnesium ion**	Co^{2+}	cobalt(II) or cobaltous ion
	Ca^{2+}	**calcium ion**	**Cu^{2+}**	**copper(II)** or cupric ion
	Sr^{2+}	strontium ion	**Fe^{2+}**	**iron(II)** or ferrous ion
	Ba^{2+}	barium ion	Mn^{2+}	manganese(II) or manganous ion
	Zn^{2+}	**zinc ion**	$Hg_2{}^{2+}$	mercury(I) or mercurous ion
	Cd^{2+}	cadmium ion	Hg^{2+}	mercury(II) or mercuric ion
			Ni^{2+}	nickel(II) or nickelous ion
			Pb^{2+}	**lead(II)** or plumbous ion
			Sn^{2+}	tin(II) or stannous ion
3+	**Al^{3+}**	**aluminum ion**	Cr^{3+}	chromium(III) or chromic ion
			Fe^{3+}	**iron(III)** or ferric ion

[a] The ions we use most often in this book are in boldface. Learn them first.

2. Anions

a. *The names of monatomic anions are formed by replacing the ending of the name of the element with* -ide:

H^-	hydride ion	O^{2-}	oxide ion	N^{3-}	nitride ion

A few polyatomic anions also have names ending in *-ide*:

OH^-	hydroxide ion	CN^-	cyanide ion	$O_2^{\,2-}$	peroxide ion

b. *Polyatomic anions containing oxygen have names ending in either* -ate *or* -ite *and are called* **oxyanions**. The suffix *-ate* is used for the most common or representative oxyanion of an element, whereas *-ite* is used for an oxyanion that has the same charge but one O atom fewer:

NO_3^-	nitrate ion	$SO_4^{\,2-}$	sulfate ion
NO_2^-	nitrite ion	$SO_3^{\,2-}$	sulfite ion

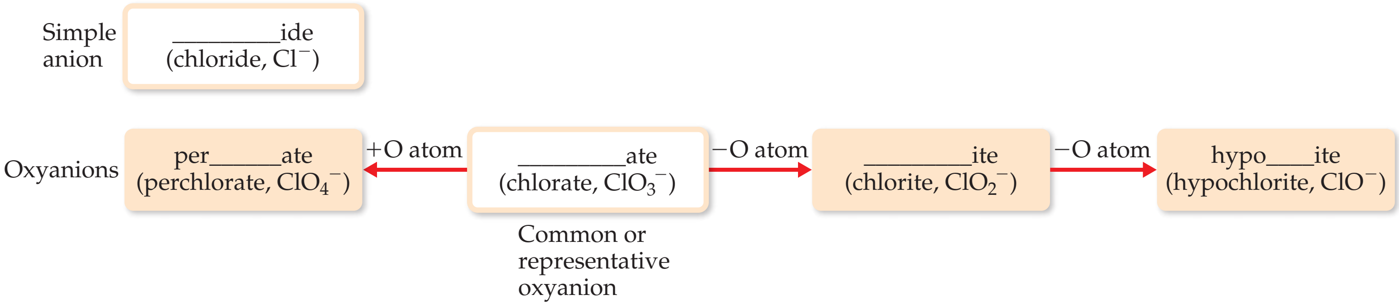
Prefixes are used when the series of oxyanions of an element extends to four members, as with the halogens. The prefix *per-* indicates one more O atom than the oxyanion ending in *-ate*; *hypo-* indicates one O atom fewer than the oxyanion ending in *-ite*:

ClO_4^-	perchlorate ion (one more O atom than chlorate)
ClO_3^-	chlorate ion
ClO_2^-	chlorite ion (one O atom fewer than chlorate)
ClO^-	hypochlorite ion (one O atom fewer than chlorite)

These rules are summarized in **Figure 2.22**.

Go Figure

Name the anion obtained by removing one oxygen atom from the perbromate ion, BrO_4^-.



▲ **Figure 2.22 Procedure for naming anions.** Here the simple anion and polyatomic oxyanions derived from chlorine are used as an example.

Figure 2.23 can help you remember the charge and number of oxygen atoms in the various oxyanions. Notice that when the central atom is from the second period (C and N), the maximum number of oxygen atoms found in an oxyanion is three, whereas when the central atom is from period 3 (or greater), the maximum number of oxygen atoms increases to four.

Beginning at the lower right in Figure 2.23, note that ionic charge increases from right to left, from 1− for ClO_4^- to 3− for $PO_4^{\,3-}$. In the second period, the charges also increase from right to left, from 1− for NO_3^- to 2− for $CO_3^{\,2-}$. Notice also that although each of the anions in Figure 2.24 ends in *-ate*, the ClO_4^- ion also has a *per-* prefix.

	Group 4A	Group 5A	Group 6A	Group 7A
Period 2	CO_3^{2-} **Carbonate ion**	NO_3^- **Nitrate ion**		
Period 3		PO_4^{3-} **Phosphate ion**	SO_4^{2-} **Sulfate ion**	ClO_4^- **Perchlorate ion**

Maximum of three O atoms in period 2.

Maximum of four O atoms in period 3.

Charges increase right to left.

▲ **Figure 2.23 Common oxyanions.** The composition and charges of common oxyanions are related to their location in the periodic table.

Sample Exercise 2.11

Determining the Formula of an Oxyanion from Its Name

Based on the formula for the sulfate ion, predict the formula for (**a**) the selenate ion and (**b**) the selenite ion. (Sulfur and selenium are both in group 6A and form analogous oxyanions.)

SOLUTION

(**a**) The sulfate ion is SO_4^{2-}. The analogous selenate ion is therefore SeO_4^{2-}.

(**b**) The ending *-ite* indicates an oxyanion with the same charge but one O atom fewer than the corresponding oxyanion that ends in *-ate*. Thus, the formula for the selenite ion is SeO_3^{2-}.

▶ Practice Exercise

The formula for the bromate ion is analogous to that for the chlorate ion. Write the formula for the hypobromite and bromite ions.

c. *Anions derived by adding H^+ to an oxyanion are named by adding as a prefix the word* hydrogen *or* dihydrogen*, as appropriate:*

CO_3^{2-}	carbonate ion	PO_4^{3-}	phosphate ion
HCO_3^-	hydrogen carbonate ion	$H_2PO_4^-$	dihydrogen phosphate ion

Notice that each H^+ added reduces the negative charge of the parent anion by one. An older method for naming some of these ions uses the prefix *bi-*. Thus, the HCO_3^- ion is commonly called the bicarbonate ion, and HSO_4^- is sometimes called the bisulfate ion.

The names and formulas of the common anions are listed in **Table 2.5** and on the back inside cover of the text. Those anions whose names end in *-ide* are listed on the left portion of Table 2.5, whereas those whose names end in *-ate* are listed on the right. The most common of these ions are shown in boldface. You should learn the names and formulas of the boldfaced anions first. The formulas of the ions whose names end with *-ite* can be derived from those ending in *-ate* by removing an O atom. Notice the location of the monatomic ions in the periodic table. Those of group 7A always have a 1− charge (F^-, Cl^-, Br^-, and I^-), and those of group 6A have a 2− charge (O^{2-} and S^{2-}).

3. Ionic Compounds

Names of ionic compounds consist of the cation name followed by the anion name:

$CaCl_2$	calcium chloride
$Al(NO_3)_3$	aluminum nitrate
$Cu(ClO_4)_2$	copper(II) perchlorate (or cupric perchlorate)

In the chemical formulas for aluminum nitrate and copper(II) perchlorate, parentheses followed by the appropriate subscript are used because the compounds contain two or more polyatomic ions.

TABLE 2.5 Common Anions[a]

Charge	Formula	Name	Formula	Name
1−	H^-	hydride ion	**CH_3COO^-** (or $C_2H_3O_2^-$)	**acetate ion**
	F^-	**fluoride ion**	ClO_3^-	chlorate ion
	Cl^-	**chloride ion**	**ClO_4^-**	**perchlorate ion**
	Br^-	**bromide ion**	**NO_3^-**	**nitrate ion**
	I^-	**iodide ion**	MnO_4^-	permanganate ion
	CN^-	cyanide ion		
	OH^-	**hydroxide ion**		
2−	**O^{2-}**	**oxide ion**	**CO_3^{2-}**	**carbonate ion**
	O_2^{2-}	peroxide ion	CrO_4^{2-}	chromate ion
	S^{2-}	**sulfide ion**	$Cr_2O_7^{2-}$	dichromate ion
			SO_4^{2-}	**sulfate ion**
3−	N^{3-}	nitride ion	**PO_4^{3-}**	**phosphate ion**

[a] The ions we use most often are in boldface. Learn them first.

Sample Exercise 2.12

Determining the Names of Ionic Compounds from Their Formulas

Name the ionic compounds (**a**) K_2SO_4, (**b**) $Ba(OH)_2$, (**c**) $FeCl_3$.

SOLUTION

In naming ionic compounds, it is important to recognize polyatomic ions and to determine the charge of cations with variable charge.

(**a**) The cation is K^+, the potassium ion, and the anion is SO_4^{2-}, the sulfate ion, making the name *potassium sulfate*. (If you thought the compound contained S^{2-} and O^{2-} ions, you failed to recognize the polyatomic sulfate ion.)

(**b**) The cation is Ba^{2+}, the barium ion, and the anion is OH^-, the hydroxide ion: barium hydroxide.

(**c**) You must determine the charge of Fe in this compound because an iron atom can form more than one cation. Because the compound contains three chloride ions, Cl^-, the cation must be Fe^{3+}, the iron(III), or ferric, ion. Thus, the compound is iron(III) chloride or ferric chloride.

Practice Exercise

Name the ionic compounds (**a**) NH_4Br, (**b**) Cr_2O_3, (**c**) $Co(NO_3)_2$.

Names and Formulas of Inorganic Acids

Acids are an important class of hydrogen-containing compounds, and they are named in a special way. For our present purposes, an *acid* is a substance whose molecules yield hydrogen ions (H^+) when dissolved in water. Acids may be inorganic, such as hydrochloric acid (HCl); or they may be organic, such as acetic acid (CH_3COOH, where the COOH is the fragment that produces hydrogen ions in water, also creating CH_3COO^- anions). Right now we focus only on inorganic acids. When we encounter the chemical formula for an inorganic acid at this stage of the course, it will be written with H as the first element, as in HCl and H_2SO_4.

An acid is composed of an anion connected to enough H^+ ions to neutralize, or balance, the anion's charge. Thus, the SO_4^{2-} ion requires two H^+ ions, forming H_2SO_4. The name of an acid is related to the name of its anion, as summarized in **Figure 2.24**.

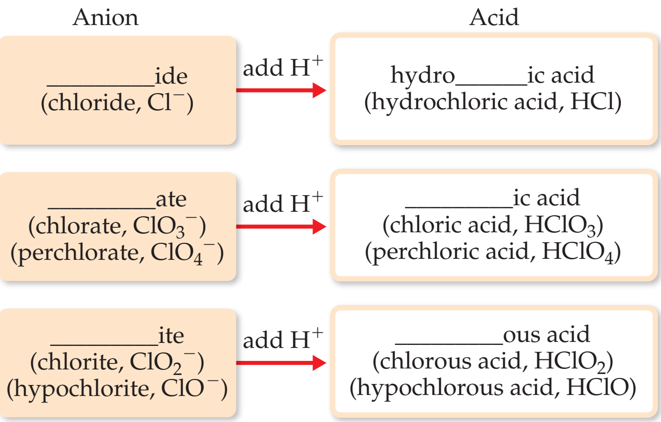
How to Name Inorganic Acids

1. *Acids containing anions whose names end in* -ide *are named by changing the* -ide *ending to* -ic, *adding the prefix* hydro- *to this anion name, and then following with the word* acid:

Anion	Corresponding Acid
Cl^- (chloride)	HCl (hydrochloric acid)
S^{2-} (sulfide)	H_2S (hydrosulfuric acid)

2. *Acids containing anions whose names end in* -ate *or* -ite *are named by changing* -ate *to* -ic *and* -ite *to* -ous*, then adding the word* acid. Prefixes in the anion name are retained in the name of the acid:

Anion		Corresponding Acid	
ClO_4^-	(perchlorate)	$HClO_4$	(perchloric acid)
ClO_3^-	(chlorate)	$HClO_3$	(chloric acid)
ClO_2^-	(chlorite)	$HClO_2$	(chlorous acid)
ClO^-	(hypochlorite)	$HClO$	(hypochlorous acid)



Anion
Acid
________ide
(chloride, Cl^-)
add H^+
hydro______ic acid
(hydrochloric acid, HCl)
________ate
(chlorate, ClO_3^-)
(perchlorate, ClO_4^-)
add H^+
________ic acid
(chloric acid, $HClO_3$)
(perchloric acid, $HClO_4$)
________ite
(chlorite, ClO_2^-)
(hypochlorite, ClO^-)
add H^+
________ous acid
(chlorous acid, $HClO_2$)
(hypochlorous acid, HClO)

▶ **Figure 2.24 Procedure for naming inorganic acids.** Here inorganic acids containing chlorine are used as an example. Prefixes used for oxyanions, such as, *per-* and *hypo-*, are retained in the acids derived from those anions.

Sample Exercise 2.13

Relating the Names and Formulas of Inorganic Acids

Name the acids (a) HCN, (b) HNO_3, (c) H_2SO_4, (d) H_2SO_3.

SOLUTION

(**a**) The anion from which this acid is derived is CN^-, the cyanide ion. Because this ion has an *-ide* ending, the acid is given a *hydro-* prefix and an *-ic* ending: hydrocyanic acid. Only water solutions of HCN are referred to as hydrocyanic acid. The pure compound, which is a gas under normal conditions, is called hydrogen cyanide. Both hydrocyanic acid and hydrogen cyanide are *extremely* toxic.

(**b**) Because NO_3^- is the nitrate ion, HNO_3 is called nitric acid (the *-ate* ending of the anion is replaced with an *-ic* ending in naming the acid).

(**c**) Because SO_4^{2-} is the sulfate ion, H_2SO_4 is called sulfuric acid.

(**d**) Because SO_3^{2-} is the sulfite ion, H_2SO_3 is sulfurous acid (the *-ite* ending of the anion is replaced with an *-ous* ending).

▶ **Practice Exercise**

Give the chemical formulas for (**a**) hydrobromic acid, (**b**) carbonic acid.

Names and Formulas of Binary Molecular Compounds

The procedures used for naming *binary* (two-element) molecular compounds are similar to those used for naming ionic compounds:

How to Name Binary Molecular Compounds

1. *The name of the element farther to the left in the periodic table (closest to the metals) is usually written first.* An exception occurs when the compound contains oxygen and chlorine, bromine, or iodine (any halogen except fluorine), in which case oxygen is written last.
2. *If both elements are in the same group, the one closer to the bottom of the table is named first.*

3. *The name of the second element is given an* -ide *ending.*
4. *Greek prefixes* (Table 2.6) indicate the number of atoms of each element. (Exception: The prefix *mono-* is never used with the first element.) When the prefix ends in *a* or *o* and the name of the second element begins with a vowel, the *a* or *o* of the prefix is often dropped.

The following examples illustrate these rules:

Cl_2O	dichlorine monoxide	NF_3	nitrogen trifluoride
N_2O_4	dinitrogen tetroxide	P_4S_{10}	tetraphosphorus decasulfide

Rule 4 is necessary because we cannot predict formulas for most molecular substances the way we can for ionic compounds. Molecular compounds that contain hydrogen and one other element are an important exception, however. These compounds can be treated as if they were neutral substances containing H^+ ions and anions. Thus, you can predict that the substance named hydrogen chloride has the formula HCl, containing one H^+ to balance the charge of one Cl^-. (The name *hydrogen chloride* is used only for the pure compound; water solutions of HCl are called hydrochloric acid. The distinction, which is important, is explained in Section 4.1.) Similarly, the formula for hydrogen sulfide is H_2S because two H^+ ions are needed to balance the charge on S^{2-}.

TABLE 2.6 Prefixes Used in Naming Binary Compounds Formed between Nonmetals

Prefix	Meaning
mono-	1
di-	2
tri-	3
tetra-	4
penta-	5
hexa-	6
hepta-	7
octa-	8
nona-	9
deca-	10

Sample Exercise 2.14

Relating the Names and Formulas of Binary Molecular Compounds

Name the compounds (**a**) SO_2, (**b**) PCl_5, (**c**) Cl_2O_3.

SOLUTION

The compounds consist entirely of nonmetals, so they are molecular rather than ionic. Using the prefixes listed in Table 2.6, we have (**a**) sulfur dioxide, (**b**) phosphorus pentachloride, (**c**) dichlorine trioxide.

Practice Exercise

Give the chemical formulas for (**a**) silicon tetrabromide, (**b**) disulfur dichloride, (**c**) diphosphorus hexaoxide.

Self-Assessment Exercises

SAE 2.23 What is the empirical formula for ammonium nitrite? (**a**) NH_3NO_3 (**b**) NH_4NO_3 (**c**) NH_3NO_2 (**d**) NH_4NO_2

SAE 2.24 Which acid has the most oxygen atoms in its chemical formula? (**a**) hypobromous acid (**b**) selenic acid (**c**) chlorous acid (**d**) nitric acid

SAE 2.25 Which molecular compound has the smallest number of atoms per molecule? (**a**) carbon disulfide (**b**) gallium trichloride (**c**) silicon tetrabromide (**d**) nitrogen monoxide (also called nitric oxide)

2.9 | Some Simple Organic Compounds

The study of compounds of carbon is called **organic chemistry**, and as noted earlier, compounds that contain carbon and hydrogen, often in combination with oxygen, nitrogen, or other elements, are called *organic compounds*. Organic compounds are a very important part of chemistry, far outnumbering all other types of chemical substances. We examine organic compounds in a systematic way in Chapter 24, but you will encounter many examples of them throughout the text. Here we present a brief introduction to some of the simplest organic compounds and the ways in which they are named.

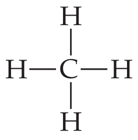
Learning Objectives

When you finish Section 2.9, you should be able to:

- Interconvert between alkane name, condensed structural formula, structural formula, and molecular formula.
- Recognize and draw structural formulas for isomers of alkanes.
- Distinguish between alcohols and carboxylic acids.
- Recognize and draw structural formulas for isomers of alcohols and carboxylic acids.

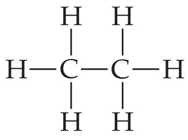
Alkanes

Compounds that contain only carbon and hydrogen are called **hydrocarbons**. In the simplest class of hydrocarbons, **alkanes**, each carbon is bonded to four other atoms. The three smallest alkanes are methane (CH_4), ethane (C_2H_6), and propane (C_3H_8). The structural formulas of these three alkanes are as follows:



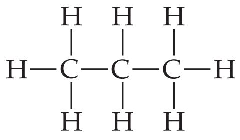
$$\begin{array}{ccccc} & & H & & \\ & & | & & \\ H & - & C & - & H \\ & & | & & \\ & & H & & \end{array}$$

Methane



$$\begin{array}{ccccccc} & & H & & H & & \\ & & | & & | & & \\ H & - & C & - & C & - & H \\ & & | & & | & & \\ & & H & & H & & \end{array}$$

Ethane



$$\begin{array}{ccccccccc} & & H & & H & & H & & \\ & & | & & | & & | & & \\ H & - & C & - & C & - & C & - & H \\ & & | & & | & & | & & \\ & & H & & H & & H & & \end{array}$$

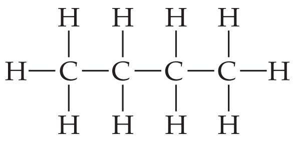
Propane

Although hydrocarbons are binary molecular compounds, they are not named like the binary inorganic compounds discussed in Section 2.8. Instead, each alkane has a name that ends in *-ane*. The alkane with four carbons is called *butane*. For alkanes with five or more carbons, the names are derived from prefixes like those in Table 2.6. An alkane with eight carbon atoms, for example, is *octane* (C_8H_{18}), where the *octa-* prefix for eight is combined with the *-ane* ending for an alkane. The first 10 "straight-chain" alkanes, those with linear chains of carbons atoms, are listed in **Table 2.7**.

TABLE 2.7 First 10 Members of the Straight-Chain Alkane Series

Molecular Formula	Condensed Structural Formula	Name	Boiling Point (°C)
CH_4	CH_4	Methane	−161
C_2H_6	CH_3CH_3	Ethane	−89
C_3H_8	$CH_3CH_2CH_3$	Propane	−44
C_4H_{10}	$CH_3CH_2CH_2CH_3$	Butane	−0.5
C_5H_{12}	$CH_3CH_2CH_2CH_2CH_3$	Pentane	36
C_6H_{14}	$CH_3CH_2CH_2CH_2CH_2CH_3$	Hexane	68
C_7H_{16}	$CH_3CH_2CH_2CH_2CH_2CH_2CH_3$	Heptane	98
C_8H_{18}	$CH_3CH_2CH_2CH_2CH_2CH_2CH_2CH_3$	Octane	125
C_9H_{20}	$CH_3CH_2CH_2CH_2CH_2CH_2CH_2CH_2CH_3$	Nonane	151
$C_{10}H_{22}$	$CH_3CH_2CH_2CH_2CH_2CH_2CH_2CH_2CH_2CH_3$	Decane	174

The formulas for the alkanes listed in Table 2.7 are written in a notation called *condensed structural formulas*. This notation reveals the way in which atoms are bonded to one another but does not require drawing in all the bonds. For example, the structural formula and the condensed structural formulas for butane (C_4H_{10}) are



$$\begin{array}{ccccccccccc} & & H & & H & & H & & H & & \\ & & | & & | & & | & & | & & \\ H & - & C & - & C & - & C & - & C & - & H \\ & & | & & | & & | & & | & & \\ & & H & & H & & H & & H & & \end{array}$$

$$H_3C{-}CH_2{-}CH_2{-}CH_3$$

or

$$CH_3CH_2CH_2CH_3$$

Isomers

Compounds that have the same molecular formula but different arrangements of atoms are called **isomers**. There are many kinds of isomers in chemistry, as we explain throughout this book. Methane, ethane, and propane have only one isomer. But once we get to butane and larger alkanes, *branched-chain* hydrocarbons are possible and do exist (**Table 2.8**). These are also called **structural isomers**, meaning that the only difference between the compounds is their molecular structure.

TABLE 2.8 **Isomers of C_4H_{10} and C_5H_{12}**

Systematic Name (Common Name)	Structural Formula	Condensed Structural Formula	Space-Filling Model
Butane (*n*-butane)		$CH_3CH_2CH_2CH_3$	
2-Methylpropane (isobutane)		 $CH_3-\underset{\displaystyle CH_3}{\underset{\vert}{CH}}-CH_3$	
Pentane (*n*-pentane)		$CH_3CH_2CH_2CH_2CH_3$	
2-Methylbutane (isopentane)		 $CH_3-\overset{\displaystyle CH_3}{\overset{\vert}{CH}}-CH_2-CH_3$	
2,2-Dimethylpropane (neopentane)		 $CH_3-\overset{\displaystyle CH_3}{\overset{\vert}{\underset{\displaystyle CH_3}{\underset{\vert}{C}}}}-CH_3$	

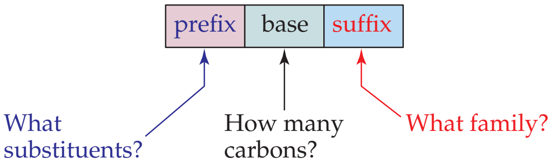
The number of possible structural isomers increases rapidly with the number of carbon atoms in the alkane. There are 18 isomers with the molecular formula C_8H_{18}, for example, and 75 with the molecular formula $C_{10}H_{22}$.

Nomenclature of Alkanes

In the first column of Table 2.8, the names in parentheses are called the *common names*. The common name of the isomer with no branches begins with the letter *n* (indicating the "normal" structure). When one CH_3 group branches off the major chain, the common name of the isomer begins with *iso*-, and when two CH_3 groups branch off, the common name begins with *neo*-. As the number of isomers grows, however, it becomes impossible to find a suitable prefix to denote each isomer by a common name. The need for a systematic means of naming organic compounds was recognized as early as 1892, when an organization called the International Union of Chemistry met in Geneva to formulate rules for naming organic substances. Since that time, the task of updating the rules for naming compounds has fallen to the International Union of Pure and Applied

Chemistry (IUPAC). Chemists everywhere, regardless of their nationality, subscribe to a common system for naming compounds.

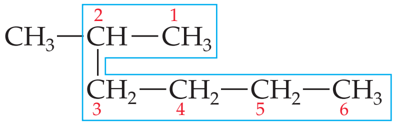
The IUPAC names for the isomers of butane and pentane are the ones given first in Table 2.8. These systematic names, as well as those of other organic compounds, have three parts:



The following steps summarize the procedures used to name alkanes, all of which have names ending with *-ane*. We use a similar approach to write the names of other organic compounds.

How to Name Alkanes

1. *Find the longest continuous chain of carbon atoms, and use the name of this chain (given in Table 2.7) as the base name.* Be careful in this step because the longest chain may not be written in a straight line, as in the following structure:



2-Methyl*hexane*

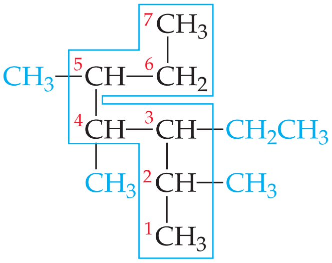
Because the longest continuous chain contains six C atoms, this isomer is named as a substituted hexane. Groups attached to the main chain are called *substituents* because they are substituted in place of an H atom on the main chain. In this molecule, the CH_3 group not enclosed by the blue outline is the only substituent in the molecule.

2. *Number the carbon atoms in the longest chain, beginning with the end nearest a substituent.* In our example, we number the C atoms beginning at the upper right because that places the CH_3 substituent on C2 of the chain. (If we had numbered from the lower right, the CH_3 would be on C5.) The chain is numbered from the end that gives the lower number to the substituent position.

3. *Name each substituent.* A substituent formed by removing an H atom from an alkane is called an **alkyl group**. Alkyl groups are named by replacing the *-ane* ending of the alkane name with *-yl*. The methyl group (CH_3), for example, is derived from methane (CH_4) and the ethyl group (C_2H_5) is derived from ethane (C_2H_6). **Table 2.9** lists six common alkyl groups.

4. *Begin the name with the number or numbers of the carbon or carbons to which each substituent is bonded.* For our compound, the name *2-methylhexane* indicates the presence of a methyl group on C2 of a hexane (six-carbon) chain.

5. *When two or more substituents are present, list them in alphabetical order.* The presence of two or more of the same substituent is indicated by the prefixes *di-* (two), *tri-* (three), *tetra-* (four), *penta-* (five), and so forth. The prefixes are ignored in determining the alphabetical order of the substituents:



3-Ethyl-2,4,5-trimethylheptane

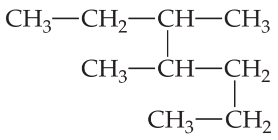
TABLE 2.9 Condensed Structural Formulas and Common Names for Several Alkyl Groups

Group	Name
$CH_3—$	Methyl
$CH_3CH_2—$	Ethyl
$CH_3CH_2CH_2—$	Propyl
$CH_3CH_2CH_2CH_2—$	Butyl
	Isopropyl
	*tert*-Butyl

Sample Exercise 2.15

Naming Alkanes

What is the systematic name for the following alkane?



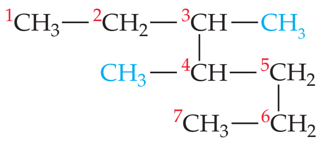
$$\begin{array}{ccccccc} CH_3 & - & CH_2 & - & CH & - & CH_3 \\ & & & & | & & \\ & & CH_3 & - & CH & - & CH_2 \\ & & & & & & | \\ & & & & CH_3 & - & CH_2 \end{array}$$

SOLUTION

Analyze We are given the condensed structural formula of an alkane and asked to give its name.

Plan Because the hydrocarbon is an alkane, its name ends in *-ane*. The name of the parent hydrocarbon is based on the longest continuous chain of carbon atoms. Branches are alkyl groups, named after the number of C atoms in the branch and located by counting C atoms along the longest continuous chain.

Solve The longest continuous chain of C atoms extends from the upper left CH_3 group to the lower left CH_3 group and is seven C atoms long:

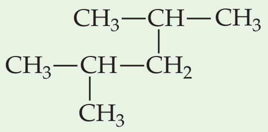


$$\begin{array}{ccccccc} {}^1CH_3 & - & {}^2CH_2 & - & {}^3CH & - & CH_3 \\ & & & & | & & \\ & & CH_3 & - & {}^4CH & - & {}^5CH_2 \\ & & & & & & | \\ & & & & {}^7CH_3 & - & {}^6CH_2 \end{array}$$

The parent compound is thus heptane. There are two methyl groups branching off the main chain. Hence, this compound is a dimethylheptane. To specify the location of the two methyl groups, we must number the C atoms so that the methyl substituents have the smallest numbers. This means that we should start numbering at the upper left carbon. There is a methyl group on C3 and one on C4. The compound is thus 3,4-dimethylheptane.

Practice Exercise

Name the following alkane:



$$\begin{array}{ccccccc} & & CH_3 & - & CH & - & CH_3 \\ & & & & | & & \\ CH_3 & - & CH & - & CH_2 & & \\ & & | & & & & \\ & & CH_3 & & & & \end{array}$$

Sample Exercise 2.16

Writing Condensed Structural Formulas

Write the condensed structural formula for 3-ethyl-2-methylpentane.

SOLUTION

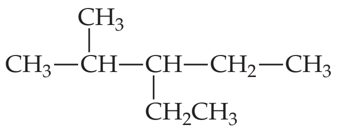
Analyze We are given the systematic name for a hydrocarbon and asked to write its condensed structural formula.

Plan Because the name ends in *-ane*, the compound is an alkane, meaning that all the carbon–carbon bonds are single bonds. The parent hydrocarbon is pentane, indicating five C atoms (Table 2.7). There are two alkyl groups specified, an ethyl group (two carbon atoms, C_2H_5) and a methyl group (one carbon atom, CH_3). Counting from left to right along the five-carbon chain, the name tells us that the ethyl group is attached to C3 and the methyl group is attached to C2.

Solve We begin by writing five C atoms attached by single bonds. These represent the backbone of the parent pentane chain:

$$C-C-C-C-C$$

We next place a methyl group on the second C and an ethyl group on the third C of the chain. We then add hydrogens to all the other C atoms to make four bonds to each carbon:



$$\begin{array}{ccccccccc} & & CH_3 & & & & & & \\ & & | & & & & & & \\ CH_3 & - & CH & - & CH & - & CH_2 & - & CH_3 \\ & & & & | & & & & \\ & & & & CH_2CH_3 & & & & \end{array}$$

The formula can be written more concisely as

$$CH_3CH(CH_3)CH(C_2H_5)CH_2CH_3$$

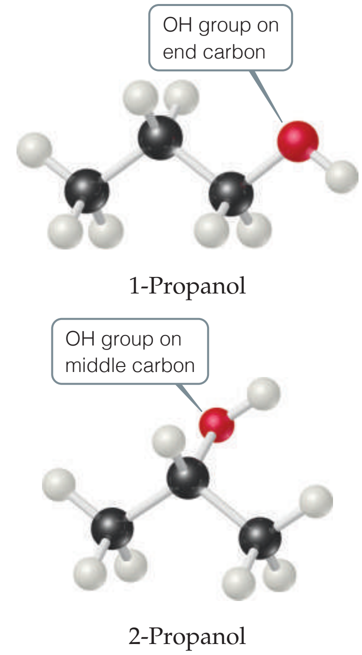
where the branching alkyl groups are indicated in parentheses.

Practice Exercise

Write the condensed structural formula for 2,3-dimethylhexane.

Alcohols and Carboxylic Acids

Other classes of organic compounds are obtained when one or more hydrogen atoms in an alkane are replaced with *functional groups*, which are specific groups of atoms. An **alcohol**, for example, is obtained by replacing an H atom of an alkane with an

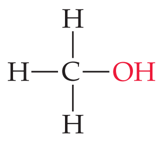


1-Propanol

2-Propanol

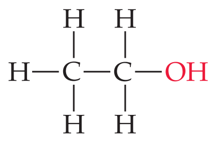
▲ **Figure 2.25** **The two isomers of propanol.**

—OH group. The name of the alcohol is derived from that of the alkane by adding an -*ol* ending:



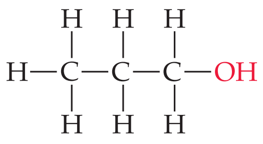
$$\begin{array}{ccccc} & & \mathrm{H} & & \\ & & | & & \\ \mathrm{H} & - & \mathrm{C} & - & \mathrm{OH} \\ & & | & & \\ & & \mathrm{H} & & \end{array}$$

Methanol



$$\begin{array}{ccccccc} & & \mathrm{H} & & \mathrm{H} & & \\ & & | & & | & & \\ \mathrm{H} & - & \mathrm{C} & - & \mathrm{C} & - & \mathrm{OH} \\ & & | & & | & & \\ & & \mathrm{H} & & \mathrm{H} & & \end{array}$$

Ethanol



$$\begin{array}{ccccccccc} & & \mathrm{H} & & \mathrm{H} & & \mathrm{H} & & \\ & & | & & | & & | & & \\ \mathrm{H} & - & \mathrm{C} & - & \mathrm{C} & - & \mathrm{C} & - & \mathrm{OH} \\ & & | & & | & & | & & \\ & & \mathrm{H} & & \mathrm{H} & & \mathrm{H} & & \end{array}$$

1-Propanol

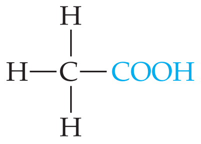
Alcohols have properties that are very different from those of the alkanes from which the alcohols are obtained. For example, methane, ethane, and propane are all colorless gases under normal conditions, whereas methanol, ethanol, and propanol are colorless liquids. We discuss the reasons for these differences in Chapter 11.

Isomers exist for alcohols and all other derivatives of alkanes. The prefix "1" in the name 1-propanol indicates that the replacement of H with OH has occurred at one of the "outer" carbon atoms rather than the "middle" carbon atom. A different compound, called either 2-propanol or isopropyl alcohol, is obtained when the OH functional group is attached to the middle carbon atom (**Figure 2.25**). If you put the —OH group on the "other" carbon, you would *not* have "3-propanol"; instead, you should just turn the molecule around and notice that it is 1-propanol, too.

Organic acids, most commonly known as **carboxylic acids**, contain the carboxylic acid group, —COOH, in place of an H in an alkane. The following are a few examples of carboxylic acids and their common names:

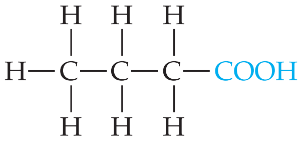
$\mathrm{H{-}COOH}$

Formic acid



$$\begin{array}{ccccc} & & \mathrm{H} & & \\ & & | & & \\ \mathrm{H} & - & \mathrm{C} & - & \mathrm{COOH} \\ & & | & & \\ & & \mathrm{H} & & \end{array}$$

Acetic acid



$$\begin{array}{ccccccccc} & & \mathrm{H} & & \mathrm{H} & & \mathrm{H} & & \\ & & | & & | & & | & & \\ \mathrm{H} & - & \mathrm{C} & - & \mathrm{C} & - & \mathrm{C} & - & \mathrm{COOH} \\ & & | & & | & & | & & \\ & & \mathrm{H} & & \mathrm{H} & & \mathrm{H} & & \end{array}$$

Butyric acid

Proper names for acids are "*x*-anoic acid," where the "*x*" is the same prefix as in Table 2.9 for the relevant number of carbon atoms. Thus, the proper name of formic acid is methanoic acid; the proper name of acetic acid is ethanoic acid; and the proper name of butyric acid is butanoic acid.

Much of the richness of organic chemistry is possible because organic compounds can form long chains of carbon–carbon bonds. They also form rings of carbon atoms that produce compounds with very different properties. The series of alkanes that begins with methane, ethane, and propane and the series of alcohols that begins with methanol, ethanol, and propanol can both be extended for as long as we desire, in principle. The properties of alkanes, alcohols, and carboxylic acids change as the chains get longer. For example, octanes, which are alkanes with eight carbon atoms, are liquids under normal conditions. (Octanes are the principal components of gasoline.) If the alkane series is extended to tens of thousands of carbon atoms, we obtain *polyethylene*, a solid substance that is used to make thousands of plastic products, such as plastic bags, food containers, and laboratory equipment. We explore much more organic chemistry throughout the book, but especially in Chapter 24.

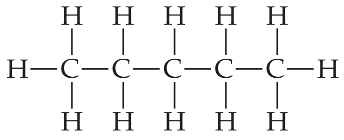
Sample Exercise 2.17

Writing Structural and Molecular Formulas for Hydrocarbons

Assuming the carbon atoms in *pentane* are in a linear chain, write (**a**) the structural formula and (**b**) the molecular formula for this alkane.

SOLUTION

(**a**) Alkanes contain only carbon and hydrogen, and each carbon is attached to four other atoms. The name *pentane* contains the prefix *penta*- for five (Table 2.6), and we are told that the carbons are in a linear chain. If we then add enough hydrogen atoms to make four bonds to each carbon, we obtain the structural formula



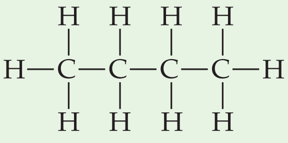
$$\begin{array}{ccccccccccccc} & & H & & H & & H & & H & & H & & \\ & & \mid & & \mid & & \mid & & \mid & & \mid & & \\ H & - & C & - & C & - & C & - & C & - & C & - & H \\ & & \mid & & \mid & & \mid & & \mid & & \mid & & \\ & & H & & H & & H & & H & & H & & \end{array}$$

This form of pentane is often called *n*-pentane, where the *n*- stands for "normal" because all five carbon atoms are in one line in the structural formula.

(**b**) Once the structural formula is written, we determine the molecular formula by counting the atoms present. Thus, *n*-pentane has the molecular formula C_5H_{12}.

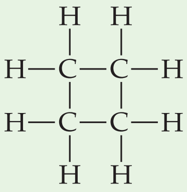
Practice Exercise

These two compounds have "butane" in their name. Are they isomers?



$$\begin{array}{ccccccccccc} & & H & & H & & H & & H & & \\ & & \mid & & \mid & & \mid & & \mid & & \\ H & - & C & - & C & - & C & - & C & - & H \\ & & \mid & & \mid & & \mid & & \mid & & \\ & & H & & H & & H & & H & & \end{array}$$

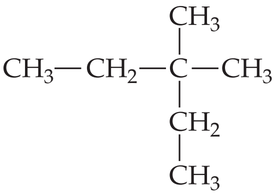
Butane



Cyclobutane

Self-Assessment Exercises

SAE 2.26 What is the systematic name of the following compound?



$$\begin{array}{ccccccc} & & & & CH_3 & & \\ & & & & \mid & & \\ CH_3 & - & CH_2 & - & C & - & CH_3 \\ & & & & \mid & & \\ & & & & CH_2 & & \\ & & & & \mid & & \\ & & & & CH_3 & & \end{array}$$

(**a**) 3-ethyl-3-methylbutane

(**d**) CH_3COCH_3

SAE 2.30 How many isomers of butyric acid are there? (**a**) 1 (**b**) 2 (**c**) 3 (**d**) 4 (**e**) 5

STRATEGIES FOR SUCCESS How to Take a Test

At about this time in your study of chemistry, you are likely to face your first examination. The best way to prepare is to study, do homework diligently, and get help from the instructor on any material that is unclear or confusing. (See the advice for learning and studying chemistry presented in the preface of the book.) Here are some general guidelines for taking tests.

Depending on the nature of your course, the exam could consist of a variety of different types of questions.

1. **Multiple-choice questions** In large-enrollment courses, the most common kind of test question is the multiple-choice question. Many of the Self-Assessment Exercises at the end of each section of this book are written in this format to give you practice at this style of question. When faced with this type of problem, the first thing to realize is that the instructor has written the question so that at first glance all the answers appear to be correct. Thus, you should not jump to the conclusion that because one of the choices looks correct, it must be correct.

   If a multiple-choice question involves a calculation, do the calculation, check your work, and *only then* compare your answer with the choices. Keep in mind, though, that your instructor has anticipated the most common errors you might make in solving a given problem and has probably listed the incorrect answers resulting from those errors. Always double-check your reasoning and use dimensional analysis to arrive at the correct numeric answer and the correct units.

   If you are not sure of the correct choice in a multiple-choice question that does *not* involve a calculation, then eliminate all the choices you know for sure to be incorrect. The reasoning you use in eliminating incorrect choices may offer insight into which of the remaining choices is correct.

2. **Calculations in which you must show your work** In questions of this kind, you may receive partial credit even if you do not arrive at the correct answer, depending on whether the instructor can follow your line of reasoning. It is

Continued

important, therefore, to be neat and organized in your calculations. Pay particular attention to what information is given and to what your unknown is. Think about how you can get from the given information to your unknown.

You may want to write a few words or a diagram on the test paper to indicate your approach. Then write out your calculations as neatly as you can. Show the units for every number you write down, and use dimensional analysis as much as you can, showing how units cancel.

3. **Questions requiring drawings** Questions of this kind will come later in the course, but it is useful to talk about them here. (You should review this box before each exam to remind yourself of good exam-taking practices.) Be sure to label your drawing as completely as possible.

Finally, if you find that you simply do not understand how to arrive at a reasoned response to a question, do not linger over the question. Put a check next to it and go on to the next one. If time permits, you can come back to the unanswered questions, but lingering over a question when nothing is coming to mind is wasting time you may need to finish the exam.

Chapter Summary and Key Terms

THE ATOMIC THEORY OF MATTER; THE DISCOVERY OF ATOMIC STRUCTURE (SECTIONS 2.1 AND 2.2) **Atoms** are the basic building blocks of matter. They are the smallest units of an element that can combine with other elements. Atoms are composed of even smaller particles, called **subatomic particles**. Some of these subatomic particles are charged and follow the usual behavior of charged particles: Particles with the same charge repel one another, whereas particles with opposite charges are attracted to one another.

We considered some of the important experiments that led to the discovery and characterization of subatomic particles. Thomson's experiments on the behavior of **cathode rays** in magnetic and electric fields led to the discovery of the electron and allowed its charge-to-mass ratio to be measured. Millikan's oil-drop experiment determined the charge of the electron. Becquerel's discovery of **radioactivity**, the spontaneous emission of radiation by atoms, gave further evidence that the atom has a substructure. Rutherford's studies of how α particles scatter when passing through thin metal foils led to the **nuclear model** of the atom, showing that the atom has a dense, positively charged **nucleus**.

THE MODERN VIEW OF ATOMIC STRUCTURE (SECTION 2.3) Atoms have a nucleus that contains **protons** and **neutrons**; **electrons** move in the space around the nucleus. The magnitude of the charge of the electron, $1.602 \times 10^{-19}\,\mathrm{C}$, is called the **electronic charge**. The charges of particles are usually represented as multiples of this charge—an electron has a 1− charge, and a proton has a 1+ charge. The masses of atoms are usually expressed in terms of **atomic mass units** ($1\,\mathrm{amu} = 1.66054 \times 10^{-24}\,\mathrm{g}$). The dimensions of atoms are often expressed in units of **angstroms** ($1\,\text{Å} = 10^{-10}\,\mathrm{m}$).

Elements can be classified by **atomic number**, the number of protons in the nucleus of an atom. All atoms of a given element have the same atomic number. The **mass number** of an atom is the sum of the numbers of protons and neutrons. Atoms of the same element that differ in mass number are known as **isotopes**.

ATOMIC WEIGHTS (SECTION 2.4) The atomic mass scale is defined by assigning a mass of exactly 12 amu to a $^{12}\mathrm{C}$ atom. The **atomic weight** (average atomic mass) of an element can be calculated from the relative abundances and masses of that element's isotopes. The **mass spectrometer** provides the most direct and accurate means of experimentally measuring atomic (and molecular) weights.

THE PERIODIC TABLE (SECTION 2.5) The **periodic table** is an arrangement of the elements in order of increasing atomic number. Elements with similar properties are placed in vertical columns. The elements in a column are known as a **group**. The elements in a horizontal row are known as a **period**. The **metallic elements** (**metals**), which comprise the majority of the elements, dominate the left side and the middle of the table; the **nonmetallic elements (nonmetals)** are located on the upper right side. Many of the elements that lie along the line that separates metals from nonmetals are **metalloids**.

MOLECULES AND MOLECULAR COMPOUNDS (SECTION 2.6) Atoms can combine to form **molecules**. Compounds composed of molecules (**molecular compounds**) usually contain only nonmetallic elements. A molecule that contains two atoms is called a **diatomic molecule**. The composition of a substance is given by its **chemical formula**. A molecular substance can be represented by its **empirical formula**, which gives the relative numbers of atoms of each kind, but is usually represented by its **molecular formula**, which gives the actual numbers of each type of atom in a molecule. **Structural formulas** show the order in which the atoms in a molecule are connected. **Ball-and-stick models** and **space-filling models** convey additional information about the shapes of molecules.

IONS AND IONIC COMPOUNDS (SECTION 2.7) Atoms can either gain or lose electrons, forming charged particles called **ions**. Metals tend to lose electrons, becoming positively charged ions (**cations**). Nonmetals tend to gain electrons, forming negatively charged ions (**anions**). Because **ionic compounds** are electrically neutral, containing both cations and anions, they usually contain both metallic and nonmetallic elements. Atoms that are joined together, as in a molecule, but carry a net charge are called **polyatomic ions**. The chemical formulas used for ionic compounds are empirical formulas, which can be written readily if the charges of the ions are known. The total positive charge of the cations in an ionic compound must equal the total negative charge of the anions.

NAMING INORGANIC COMPOUNDS (SECTION 2.8) The set of rules for naming chemical compounds is called **chemical nomenclature**. We studied the systematic rules used for naming three classes of inorganic substances: ionic compounds, inorganic acids, and binary molecular compounds. In naming an ionic compound, the cation is named first and then the anion. Cations formed from metal atoms have the same name as the metal. If the metal can form cations of differing charges, the charge is indicated using Roman numerals. Monatomic anions have names ending in *ide*. Polyatomic anions containing oxygen and another element (**oxyanions**) have names ending in *ate* or *ite*. In naming binary molecular compounds, Greek prefixes are used to denote the number of each element in the molecular formula, and the element farthest to the left in the periodic table (closest to metallic elements) is generally written first.

SOME SIMPLE ORGANIC COMPOUNDS (SECTION 2.9) **Organic chemistry** is the study of compounds that contain carbon. The simplest class of organic molecules is the **hydrocarbons**, which contain only carbon and hydrogen. Hydrocarbons in which each carbon atom is attached to four other atoms are called **alkanes**. Alkanes have names that end in *ane*, such as methane and ethane. Other organic compounds are formed when an H atom of a hydrocarbon is replaced with a functional group. An **alcohol**, for example, is a compound in which an H atom of a hydrocarbon is replaced by an OH functional group. Alcohols have names that end in *ol*, such as methanol and ethanol. **Organic acids** (also called **carboxylic acids**) contain the COOH functional group. Compounds with the same molecular formula but different bonding arrangements of their constituent atoms are called **isomers**.

Key Equations

- Atomic weight $= \sum_{\substack{\text{over}\\ \text{all isotopes}}} [(\text{fractional isotope abundance}) \times (\text{isotope mass})]$ [2.1] Calculating atomic weight as a fractionally weighted average of isotopic masses.

Exam Prep

EP 2.1 Which of the following factors determines the size of an atom? (**a**) the volume of the nucleus (**b**) the volume of space occupied by the electrons of the atom (**c**) the volume of a single electron, multiplied by the number of electrons in the atom (**d**) the total nuclear charge (**e**) the total mass of the electrons surrounding the nucleus.

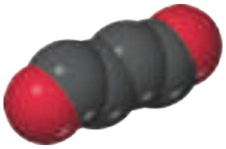
EP 2.2 Which of these atoms has the largest number of neutrons? (**a**) ^{148}Eu (**b**) ^{157}Dy (**c**) ^{149}Nd (**d**) ^{162}Ho

EP 2.3 Which of the following is an incorrect representation for a neutral atom? (**a**) $^{6}_{3}$Li (**b**) $^{13}_{6}$C (**c**) $^{63}_{30}$Cu (**d**) $^{30}_{15}$P (**e**) $^{108}_{47}$Ag

EP 2.4 There are two stable isotopes of copper found in nature, ^{63}Cu and ^{65}Cu. If the atomic weight of copper Cu is 63.546 amu, which of the following statements are true? (**a**) ^{65}Cu contains two more protons than ^{63}Cu. (**b**) ^{63}Cu must be more abundant than ^{65}Cu. (**c**) All copper atoms have a mass of 63.546 amu.

EP 2.5 A biochemist who is studying the properties of certain sulfur (S)–containing compounds in the body wonders whether trace amounts of another nonmetallic element might have similar behavior. To which element should she turn her attention? (**a**) F (**b**) As (**c**) Se (**d**) Cr (**e**) P

EP 2.6 Tetracarbon dioxide is an unstable oxide of carbon with the following molecular structure:



What are the molecular and empirical formulas of this substance? (**a**) C_2O_2, CO_2 (**b**) C_4O, CO (**c**) C_4O_2, CO_2 (**d**) C_4O_2, C_2O (**e**) C_2O, CO_2

EP 2.7 In which of the following species is the difference between the number of protons and the number of electrons largest? (**a**) Ti^{2+} (**b**) P^{3-} (**c**) Mn (**d**) Se^{2-} (**e**) Ce^{4+}

EP 2.8 Although it is helpful to know that many ions have the electron arrangement of a noble gas, many elements, especially among the metals, form ions that do not have a noble-gas electron arrangement. Use the periodic table, Figure 2.14, to determine which of the following ions has a noble-gas electron arrangement: (**a**) Ti^{4+} (**b**) Mn^{2+} (**c**) Pb^{2+} (**d**) Zn^{2+}

EP 2.9 Which of these compounds is molecular? (**a**) CBr_4 (**b**) FeS (**c**) NaCl (**d**) PbF_2

EP 2.10 Which of the following nonmetals will form an ionic compound with Sc^{3+} that has a 1:1 ratio of cations to anions? (**a**) Ne (**b**) F (**c**) O (**d**) N

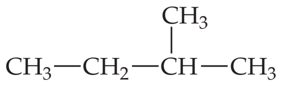
EP 2.11 Which of the following oxyanions is incorrectly named? (**a**) ClO_2^-, chlorate (**b**) IO_4^-, periodate (**c**) SO_3^{2-}, sulfite (**d**) IO_3^-, iodate (**e**) NO_2^-, nitrite

EP 2.12 Which of the following ionic compounds is incorrectly named? (**a**) $Zn(NO_3)_2$, zinc nitrate (**b**) $TeCl_4$, tellurium(IV) chloride (**c**) Fe_2O_3, diiron trioxide (**d**) BaO, barium oxide (**e**) $Mn_3(PO_4)_2$ manganese(II) phosphate

EP 2.13 Which of the following acids are incorrectly named? (**a**) hydrofluoric acid, HF (**b**) nitrous acid, HNO_3 (**c**) perbromic acid, $HBrO_4$ (**d**) hydroiodic acid, HI (**e**) selenic acid, H_2SeO_4

EP 2.14 What is the molecular formula for carbon disulfide? (**a**) CS_2 (**b**) CO (**c**) C_3O_2 (**d**) CBr_4 (**e**) CF

EP 2.15 What is the systematic name for this alkane:



$$CH_3{-}CH_2{-}\overset{\displaystyle CH_3}{\overset{|}{C}H}{-}CH_3$$

(**a**) 3,3-dimethylpropane (**b**) isobutane (**c**) 3-methylbutane (**d**) 2-methylbutane (**e**) pentane

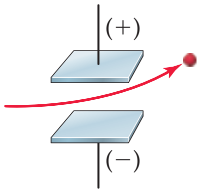
EP 2.16 What is the empirical formula of hexane? (**a**) C_6H_6 (**b**) C_6H_{15} (**c**) C_3H_7 (**d**) C_2H_6

EP 2.17 How many isomers of *n*-butanol are there? (**a**) 1 (**b**) 2 (**c**) 3 (**d**) 4

Exercises

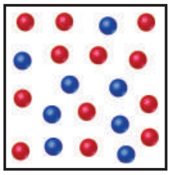
Visualizing Concepts

2.1 A charged particle moves between two electrically charged plates, as shown here.

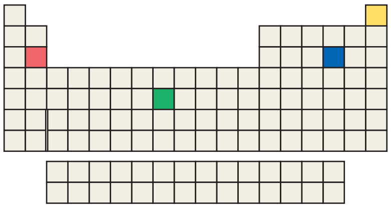


(**a**) What is the sign of the electrical charge on the particle? (**b**) As the charge on the plates is increased, would you expect the bending to increase, decrease, or stay the same? (**c**) As the mass of the particle is increased while the speed of the particles remains the same, would you expect the bending to increase, decrease, or stay the same? [Section 2.2]

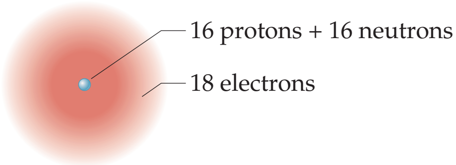
2.2 The following diagram is a representation of 20 atoms of a fictitious element, which we will call nevadium (Nv). The red spheres are ^{293}Nv, and the blue spheres are ^{295}Nv. (**a**) Assuming that this sample is a statistically representative sample of the element, calculate the percent abundance of each element. (**b**) If the mass of ^{293}Nv is 293.15 amu and that of ^{295}Nv is 295.15 amu, what is the atomic weight of Nv? [Section 2.4]



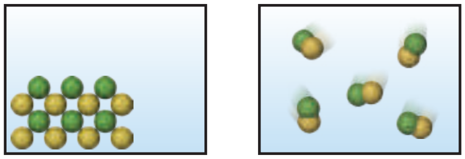
2.3 Four of the boxes in the following periodic table are colored. Which of these are metals and which are nonmetals? Which one is an alkaline earth metal? Which one is a noble gas? Which is a transition metal? [Section 2.5]



2.4 Does the following drawing represent a neutral atom or an ion? Write its complete chemical symbol, including mass number, atomic number, and net charge (if any). [Sections 2.3 and 2.7]

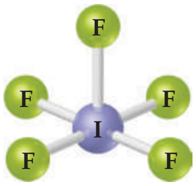


2.5 (**a**) Which of the following diagrams most likely represents an ionic compound? (**b**) Which of the following diagrams most likely represents a molecular compound? [Sections 2.6 and 2.7]

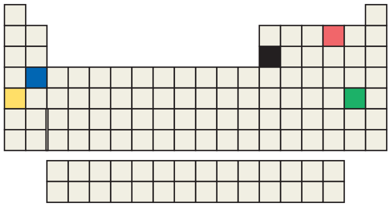


(i) (ii)

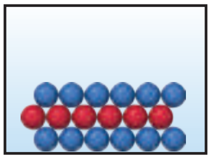
2.6 Write the chemical formula for the following compound. Is the compound ionic or molecular? Name the compound. [Sections 2.6 and 2.8]



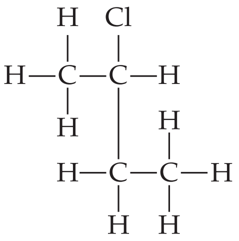
2.7 Five of the boxes in the following periodic table are colored. Predict the charge on the ion associated with each of these elements. [Section 2.7]

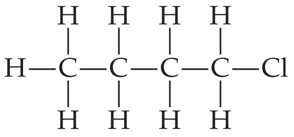


2.8 The following diagram represents an ionic compound in which the red spheres represent cations and the blue spheres represent anions. Which of the following compounds is consistent with the drawing? (**a**) potassium bromide (**b**) potassium sulfate (**c**) calcium nitrate (**d**) iron(III) sulfate [Sections 2.7 and 2.8]

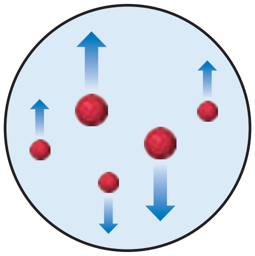


2.9 Are these two compounds isomers? [Section 2.9]





2.10 In the Millikan oil-drop experiment (see Figure 2.5), the tiny oil drops are observed through the viewing lens as rising, stationary, or falling, as shown here. The arrows indicate the rate of motion. (**a**) What causes their rate of fall to vary from their rate in the absence of an electric field? (**b**) Why do some drops move upward? [Section 2.2]



The Atomic Theory of Matter and the Discovery of Atomic Structure (Sections 2.1 and 2.2)

2.11 A 1.0-g sample of carbon dioxide (CO_2) is fully decomposed into its elements, yielding 0.273 g of carbon and 0.727 g of oxygen. (**a**) What is the ratio of the mass of O to C? (**b**) If a sample of a different compound decomposes into 0.429 g of carbon and 0.571 g of oxygen, what is its ratio of the mass of O to C? (**c**) According to Dalton's atomic theory, what is the empirical formula of the second compound?

2.12 Hydrogen sulfide is composed of two elements: hydrogen and sulfur. In an experiment, 6.500 g of hydrogen sulfide is fully decomposed into its elements. (**a**) If 0.384 g of hydrogen is obtained in this experiment, how many grams of sulfur must be obtained? (**b**) What fundamental law does this experiment demonstrate?

2.13 A chemist finds that 30.82 g of nitrogen will react with 17.60, 35.20, 70.40, or 88.00 g of oxygen to form four different compounds. (**a**) Calculate the mass of oxygen per gram of nitrogen in each compound. (**b**) How do the numbers in part (**a**) support Dalton's atomic theory?

2.14 In a series of experiments, a chemist prepared three different compounds that contain only iodine and fluorine and determined the mass of each element in each compound:

Compound	Mass of Iodine (g)	Mass of Fluorine (g)
1	4.75	3.56
2	7.64	3.43
3	9.41	9.86

(**a**) Calculate the mass of fluorine per gram of iodine in each compound. (**b**) How do the numbers in part (**a**) support the atomic theory?

2.15 Which of the subatomic particles in an atom does not have a charge (and was therefore the last to be discovered)?

2.16 An unknown particle is caused to move between two electrically charged plates, as illustrated in Figure 2.7. You hypothesize that the particle is a proton. (**a**) If your hypothesis is correct, would the particle be deflected in the same or opposite direction as the β rays? (**b**) Would it be deflected by a smaller or larger amount than the β rays?

2.17 Which set of statements is true about Rutherford's gold foil experiment?

(**i**) This is the main experiment that showed that atoms have a dense nucleus.
(**ii**) The data from the experiment showed that alpha particles scattered equally at all angles from the gold foil.
(**iii**) Electrons were emitted from the gold atoms in straight lines.

(**a**) i only (**b**) ii only (**c**) iii only (**d**) i and ii (**e**) i and iii

2.18 Millikan determined the charge on the electron by studying the static charges on oil drops falling in an electric field (Figure 2.5). A student carried out this experiment using several oil drops for her measurements and calculated the charges on the drops. She obtained the following data:

Droplet	Calculated Charge (C)
A	1.60×10^{-19}
B	3.15×10^{-19}
C	4.81×10^{-19}
D	6.31×10^{-19}

(**a**) What is the significance of the fact that the droplets carried different charges? (**b**) What conclusion can the student draw from these data regarding the charge of the electron? (**c**) What value (and to how many significant figures) should she report for the electronic charge?

The Modern View of Atomic Structure; Atomic Weights (Sections 2.3 and 2.4)

2.19 The radius of an atom of gold (Au) is about 1.35 Å. (**a**) Express this distance in nanometers (nm) and in picometers (pm). (**b**) How many gold atoms would have to be lined up to span 1.0 mm? (**c**) If the atom is assumed to be a sphere, what is the volume in cm^3 of a single Au atom?

2.20 An atom of rhodium (Rh) has a diameter of about 2.7×10^{-8} cm. (**a**) What is the radius of a rhodium atom in angstroms (Å) and in meters (m)? (**b**) How many Rh atoms would have to be placed side by side to span a distance of 6.0 μm? (**c**) If you assume that the Rh atom is a sphere, what is the volume in m^3 of a single atom?

2.21 Answer the following questions without referring to Table 2.1. (**a**) What are the main subatomic particles that make up the atom? (**b**) What is the relative charge (in multiples of the electronic charge) of each of the particles? (**c**) Which of the particles is the most massive? (**d**) Which is the least massive?

2.22 Determine whether each of the following statements is true or false. (**a**) The nucleus has most of the mass and comprises most of the volume of an atom. (**b**) Every atom of a given element has the same number of protons. (**c**) The number of electrons in an atom equals the number of neutrons in the atom. (**d**) The protons in the nucleus of the helium atom are held together by a force called the strong nuclear force.

2.23 Consider an atom of ^{10}B. (**a**) How many protons, neutrons, and electrons does this atom contain? (**b**) What is the symbol of the atom obtained by adding one proton to ^{10}B? (**c**) What is the symbol of the atom obtained by adding one neutron to ^{10}B? (**d**) Are either of the atoms obtained in parts (**b**) and (**c**) isotopes of ^{10}B? If so which one?

2.24 Consider an atom of ^{63}Cu. (**a**) How many protons, neutrons, and electrons does this atom contain? (**b**) What is the symbol of the ion obtained by removing two electrons from ^{63}Cu? (**c**) What is the symbol for the isotope of ^{63}Cu that possesses 36 neutrons?

2.25 (**a**) Define atomic number and mass number. (**b**) Which of these can vary without changing the identity of the element? (**c**) Which one of these is usually larger for a given element?

2.26 (**a**) Which two of the following are isotopes of the same element: $^{31}_{16}X$, $^{31}_{15}X$, $^{32}_{16}X$? (**b**) What is the identity of the element whose isotopes you have selected?

2.27 How many protons, neutrons, and electrons are in the following atoms? (**a**) ^{40}Ar (**b**) ^{65}Zn (**c**) ^{70}Ga (**d**) ^{80}Br (**e**) ^{184}W (**f**) ^{243}Am

2.28 Each of the following isotopes is used in medicine. Indicate the number of protons and neutrons in each isotope. (**a**) phosphorus-32 (**b**) chromium-51 (**c**) cobalt-60 (**d**) technetium-99 (**e**) iodine-131 (**f**) thallium-201

2.29 Fill in the gaps in the following table, assuming each column represents a neutral atom.

Symbol	^{79}Br				
Protons		25			82
Neutrons		30	64		
Electrons			48	86	
Mass no.				222	207

2.30 Fill in the gaps in the following table, assuming each column represents a neutral atom.

Symbol	^{112}Cd				
Protons		38			92
Neutrons		58	49		
Electrons			38	36	
Mass no.				81	235

2.31 Write the correct symbol, with both superscript and subscript, for each of the following. Use the list of elements in the front inside cover as needed. (**a**) the isotope of platinum that contains 118 neutrons (**b**) the isotope of krypton with mass number 84 (**c**) the isotope of arsenic with mass number 75 (**d**) the isotope of magnesium that has an equal number of protons and neutrons

2.32 Hydrogen is unusual in that its three isotopes have common chemical symbols: hydrogen (H), deuterium (D), and tritium (T). Based on these names, predict how many protons and neutrons are in the nuclei of H, D, and T.

2.33 The atomic weight of boron is reported as 10.81, yet no atom of boron has the mass of 10.81 amu. Which is the best explanation? (**a**) The measurement of atomic mass is only reliable to two significant figures. (**b**) The atomic weight is an average of many individual atoms. (**c**) The atomic weight is an average of many isotopes of the same nuclear composition.

2.34 (**a**) What is the mass in amu of a carbon-12 atom? (**b**) Why is the atomic weight of carbon reported as 12.011 in the table of elements and the periodic table in the front inside cover of this text?

2.35 Only two isotopes of copper occur naturally: ^{63}Cu (atomic mass = 62.9296 amu; abundance 69.17%) and ^{65}Cu (atomic mass = 64.9278 amu; abundance 30.83%). Calculate the atomic weight (average atomic mass) of copper.

2.36 Rubidium has two naturally occurring isotopes, rubidium-85 (atomic mass = 84.9118 amu; abundance = 72.15%) and rubidium-87 (atomic mass = 86.9092 amu; abundance = 27.85%). Calculate the atomic weight of rubidium.

2.37 (**a**) Thomson's cathode-ray tube (Figure 2.4) and the mass spectrometer (Figure 2.11) both involve the use of electric or magnetic fields to deflect charged particles. What are the charged particles involved in each of these experiments? (**b**) What are the labels on the axes of a mass spectrum? (**c**) To measure the mass spectrum of a sample of atoms, the atom must first lose one or more electrons. Which would you expect to be deflected more by the same setting of the electric and magnetic fields, a Cl^+ or a Cl^{2+} ion?

2.38 Consider the mass spectrometer shown in Figure 2.11. Determine whether each of the following statements is true or false. (**a**) The paths of neutral (uncharged) atoms are not affected by the magnet. (**b**) The height of each peak in the mass spectrum is inversely proportional to the mass of that isotope. (**c**) For a given element, the number of peaks in the spectrum is equal to the number of naturally occurring isotopes of that element.

2.39 Naturally occurring magnesium has the following isotopic abundances:

Isotope	Abundance (%)	Atomic mass (amu)
^{24}Mg	78.99	23.98504
^{25}Mg	10.00	24.98584
^{26}Mg	11.01	25.98259

(**a**) What is the average atomic mass of Mg? (**b**) Sketch the mass spectrum of Mg.

2.40 Mass spectrometry is more often applied to molecules than to atoms. We show in Chapter 3 that the *molecular weight* of a molecule is the sum of the atomic weights of the atoms in the molecule. The mass spectrum of H_2 is taken under conditions that prevent decomposition into H atoms. The two naturally occurring isotopes of hydrogen are ^1H (atomic mass $= 1.00783$ amu; abundance 99.9885%) and ^2H (atomic mass $= 2.01410$ amu; 0.0115%). (**a**) How many peaks will the mass spectrum have? (**b**) Give the relative atomic masses of each of these peaks. (**c**) Which peak will be the largest, and which the smallest?

The Periodic Table, Molecules, Molecular Compounds, Ions, and Ionic Compounds (Sections 2.5, 2.6, and 2.7)

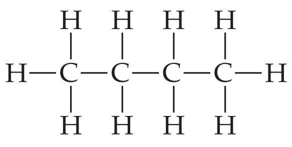
2.41 For each of the following elements, write its chemical symbol, locate it in the periodic table, give its atomic number, and indicate whether it is a metal, metalloid, or nonmetal. (**a**) chromium (**b**) helium (**c**) phosphorus (**d**) zinc (**e**) magnesium (**f**) bromine (**g**) arsenic

2.42 Locate each of the following elements in the periodic table; give its name and atomic number, and indicate whether it is a metal, metalloid, or nonmetal. (**a**) Li (**b**) Sc (**c**) Ge (**d**) Yb (**e**) Mn (**f**) Sb (**g**) Xe

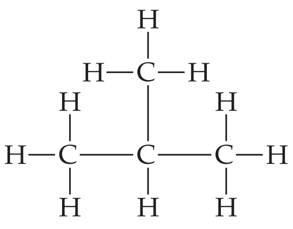
2.43 For each of the following elements, write its chemical symbol, determine the name of the group to which it belongs (Table 2.3), and indicate whether it is a metal, metalloid, or nonmetal. (**a**) potassium (**b**) iodine (**c**) magnesium (**d**) argon (**e**) sulfur

2.44 The elements of group 4A show an interesting change in properties moving down the group. Give the name and chemical symbol of each element in the group and label it as a nonmetal, metalloid, or metal.

2.45 The structural formulas of the compounds *n*-butane and isobutane are shown below. (**a**) Determine the molecular formula of each. (**b**) Determine the empirical formula of each. (**c**) Which formulas—empirical, molecular, or structural—allow you determine these are different compounds?

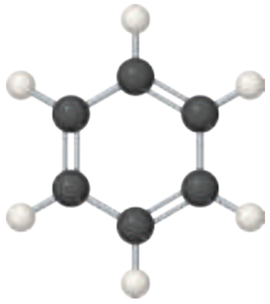


n-butane



isobutane

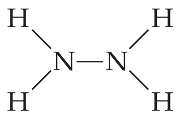
2.46 Ball-and-stick representations of benzene, a colorless liquid often used in organic chemistry reactions, and acetylene, a gas used as a fuel for high-temperature welding, are shown below. (**a**) Determine the molecular formula of each. (**b**) Determine the empirical formula of each.

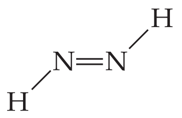


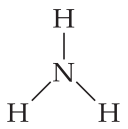
benzene

acetylene

2.47 What are the molecular and empirical formulas for each of the following compounds?







2.48 Two substances have the same molecular and empirical formulas. Does this mean that they must be the same compound?

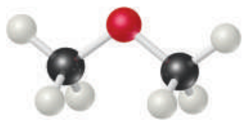
2.49 Write the empirical formula corresponding to each of the following molecular formulas. (**a**) Al_2Br_6 (**b**) C_8H_{10} (**c**) $C_4H_8O_2$ (**d**) P_4O_{10} (**e**) $C_6H_4Cl_2$ (**f**) $B_3N_3H_6$

2.50 Determine the molecular and empirical formulas of the following. (**a**) the organic solvent *cyclohexane*, which has six carbon atoms and twelve hydrogen atoms (**b**) the compound *silicon tetrachloride*, which has a silicon atom and four chlorine atoms and is used in the manufacture of computer chips (**c**) the reactive substance *diborane*, which has two boron atoms and six hydrogen atoms (**d**) the sugar called *glucose*, which has six carbon atoms, twelve hydrogen atoms, and six oxygen atoms

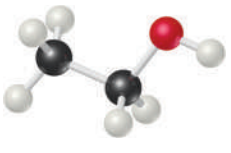
2.51 How many hydrogen atoms are in each of the following? (**a**) C_2H_5OH (**b**) $Ca(C_2H_5COO)_2$ (**c**) $(NH_4)_3PO_4$

2.52 How many of the indicated atoms are represented by each chemical formula? (**a**) carbon atoms in $C_4H_9COOCH_3$ (**b**) oxygen atoms in $Ca(ClO_3)_2$ (**c**) hydrogen atoms in $(NH_4)_2HPO_4$

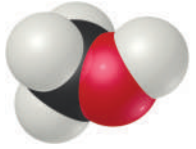
2.53 Write the molecular and structural formulas for the compounds represented by the following molecular models.



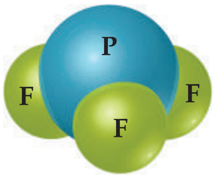
(a)



(b)

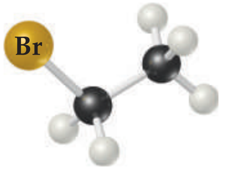


(c)

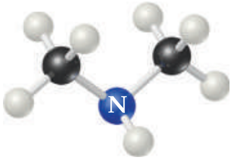


(d)

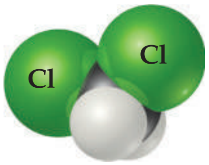
2.54 Write the molecular and structural formulas for the compounds represented by the following models.



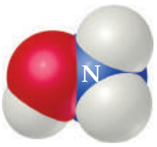
(a)



(b)



(c)



(d)

2.55 Fill in the gaps in the following table:

Symbol	$^{59}Co^{3+}$			
Protons		34	76	80
Neutrons		46	116	120
Electrons		36		78
Net charge			2+	

2.56 Fill in the gaps in the following table:

Symbol	$^{31}P^{3-}$			
Protons		34	50	
Neutrons		45	69	118
Electrons			46	76
Net charge		2−		3+

2.57 Each of the following elements is capable of forming an ion in chemical reactions. By referring to the periodic table, predict the charge of the most stable ion of each. (**a**) Mg (**b**) Al (**c**) K (**d**) S (**e**) F

2.58 Using the periodic table, predict the charges of the ions of the following elements. (**a**) Ga (**b**) Sr (**c**) As (**d**) Br (**e**) Se

2.59 Using the periodic table to guide you, predict the chemical formula and name of the compound formed by the following elements. (**a**) Ga and F (**b**) Li and H (**c**) Al and I (**d**) K and S

2.60 The most common charge associated with scandium in its compounds is 3+. Indicate the chemical formulas you would expect for compounds formed between scandium and (**a**) iodine, (**b**) sulfur, (**c**) nitrogen.

2.61 Predict the chemical formula for the ionic compound formed by (**a**) Ca^{2+} and Br^-, (**b**) K^+ and CO_3^{2-}, (**c**) Al^{3+} and CH_3COO^-, (**d**) NH_4^+ and SO_4^{2-}, (**e**) Mg^{2+} and PO_4^{3-}.

2.62 Predict the chemical formulas of the compounds formed by the following pairs of ions. (**a**) Cr^{3+} and Br^- (**b**) Fe^{3+} and O^{2-} (**c**) Hg_2^{2+} and CO_3^{2-} (**d**) Ca^{2+} and ClO_3^- (**e**) NH_4^+ and PO_4^{3-}

2.63 Complete the table by filling in the formula for the ionic compound formed by each pair of cations and anions, as shown for the first pair.

Ion	K^+	NH_4^+	Mg^{2+}	Fe^{3+}
Cl^-	KCl			
OH^-				
CO_3^{2-}				
PO_4^{3-}				

2.64 Complete the table by filling in the formula for the ionic compound formed by each pair of cations and anions, as shown for the first pair.

Ion	Na^+	Ca^{2+}	Fe^{2+}	Al^{3+}
O^{2-}	Na_2O			
NO_3^-				
SO_4^{2-}				
AsO_4^{3-}				

2.65 Predict whether each of the following compounds is molecular or ionic. (**a**) B_2H_6 (**b**) CH_3OH (**c**) $LiNO_3$ (**d**) Sc_2O_3 (**e**) CsBr (**f**) NOCl (**g**) NF_3 (**h**) Ag_2SO_4

2.66 Predict whether each of the following compounds is molecular or ionic. (**a**) PF_5 (**b**) NaI (**c**) SCl_2 (**d**) $Ca(NO_3)_2$ (**e**) $FeCl_3$ (**f**) LaP (**g**) $CoCO_3$ (**h**) N_2O_4

Naming Inorganic Compounds; Some Simple Organic Compounds (Sections 2.8 and 2.9)

2.67 Give the chemical formula for (**a**) chlorite ion, (**b**) chloride ion, (**c**) chlorate ion, (**d**) perchlorate ion, (**e**) hypochlorite ion.

2.68 Selenium, an element required nutritionally in trace quantities, forms compounds analogous to sulfur. Name the following ions. (**a**) SeO_4^{2-} (**b**) Se^{2-} (**c**) HSe^- (**d**) $HSeO_3^-$

2.69 Give the names and charges of the cation and anion in each of the following compounds. (**a**) CaO (**b**) Na_2SO_4 (**c**) $KClO_4$ (**d**) $Fe(NO_3)_2$ (**e**) $Cr(OH)_3$

2.70 Give the names and charges of the cation and anion in each of the following compounds. (**a**) CuS (**b**) Ag_2SO_4 (**c**) $Al(ClO_3)_3$ (**d**) $Co(OH)_2$ (**e**) $PbCO_3$

2.71 Name the following ionic compounds. (**a**) Li_2O (**b**) $FeCl_3$ (**c**) NaClO (**d**) $CaSO_3$ (**e**) $Cu(OH)_2$ (**f**) $Fe(NO_3)_2$ (**g**) $Ca(CH_3COO)_2$ (**h**) $Cr_2(CO_3)_3$ (**i**) K_2CrO_4 (**j**) $(NH_4)_2SO_4$

2.72 Name the following ionic compounds. (**a**) KCN (**b**) $NaBrO_2$ (**c**) $Sr(OH)_2$ (**d**) CoTe (**e**) $Fe_2(CO_3)_3$ (**f**) $Cr(NO_3)_3$ (**g**) $(NH_4)_2SO_3$ (**h**) NaH_2PO_4 (**i**) $KMnO_4$ (**j**) $Ag_2Cr_2O_7$

2.73 Write the chemical formulas for the following compounds. (**a**) aluminum hydroxide (**b**) potassium sulfate (**c**) copper(I) oxide (**d**) zinc nitrate (**e**) mercury(II) bromide (**f**) iron(III) carbonate (**g**) sodium hypobromite

2.74 Give the chemical formula for each of the following ionic compounds. (**a**) sodium phosphate (**b**) zinc nitrate (**c**) barium bromate (**d**) iron(II) perchlorate (**e**) cobalt(II) hydrogen carbonate (**f**) chromium(III) acetate (**g**) potassium dichromate

2.75 Give the name or chemical formula, as appropriate, for each of the following acids. (**a**) $HBrO_3$ (**b**) HBr (**c**) H_3PO_4 (**d**) hypochlorous acid (**e**) iodic acid (**f**) sulfurous acid

2.76 Provide the name or chemical formula, as appropriate, for each of the following acids. (**a**) hydroiodic acid (**b**) chloric acid (**c**) nitrous acid (**d**) H_2CO_3 (**e**) $HClO_4$ (**f**) CH_3COOH

2.77 Give the name or chemical formula, as appropriate, for each of the following binary molecular substances. (**a**) SF_6 (**b**) $SeCl_2$ (**c**) XeO_3 (**d**) dinitrogen tetroxide (**e**) hydrogen cyanide (**f**) tetraphosphorus hexasulfide

2.78 The oxides of nitrogen are very important components in urban air pollution. Name each of the following compounds. (**a**) N_2O (**b**) NO (**c**) NO_2 (**d**) N_2O_5 (**e**) N_2O_4

2.79 Write the chemical formula for each substance mentioned in the following word descriptions (use the front inside cover to find the symbols for the elements you do not know). (**a**) Zinc carbonate can be heated to form zinc oxide and carbon dioxide. (**b**) On treatment with hydrofluoric acid, silicon dioxide forms silicon tetrafluoride and water. (**c**) Sulfur dioxide reacts with water to form sulfurous acid. (**d**) The substance phosphorus trihydride, commonly called phosphine, is a toxic gas. (**e**) Perchloric acid reacts with cadmium to form cadmium(II) perchlorate. (**f**) Vanadium(III) bromide is a colored solid.

2.80 Assume that you encounter the following sentences in your reading. What is the chemical formula for each substance mentioned? (**a**) Sodium hydrogen carbonate is used as a deodorant. (**b**) Calcium hypochlorite is used in some bleaching solutions. (**c**) Hydrogen cyanide is a very poisonous gas. (**d**) Magnesium hydroxide is used as a cathartic. (**e**) Tin(II) fluoride has been used as a fluoride additive in toothpastes. (**f**) When cadmium sulfide is treated with sulfuric acid, fumes of hydrogen sulfide are given off.

2.81 (**a**) What elements are contained in hydrocarbons? (**b**) *n*-Octane is the alkane with a linear chain of eight carbon atoms. Write the structural formula for this compound. (**c**) What is the molecular formula of octane? (**d**) What is the empirical formula for octane?

2.82 (**a**) What is meant by the term *isomer*? (**b**) How many isomers does propane have? (**c**) How many isomers does butane have?

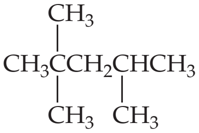
2.83 (**a**) What functional group characterizes an alcohol? (**b**) Write a structural formula for 1-pentanol.

2.84 Consider the following organic substances: ethanol, propane, hexane, and propanol. (**a**) Which of these molecules contains an OH group? (**b**) Which of these molecules contains three carbon atoms?

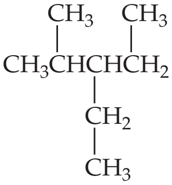
2.85 Your classmate writes out an incorrect condensed structural formula for methanol: CH_4OH. Why is this incorrect? (**a**) Alcohols should have the —COOH functional group. (**b**) There should be more than one carbon atom. (**c**) There are too many hydrogen atoms. (**d**) More than one of (a), (b), (c).

2.86 Your classmate says there are two isomers for ethanol. Are they right or not, and if so, why or why not? (**a**) The classmate is correct, because you can put the OH group on either carbon. (**b**) The classmate is correct, because you can put the COOH group on either carbon. (**c**) The classmate is not correct, there is only one isomer of ethanol. (**d**) The classmate is not correct, because there are more than two isomers of ethanol.

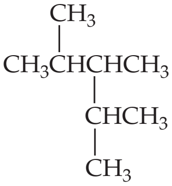
2.87 All the structures shown here have the molecular formula C_8H_{18}. Which structures are the same molecule? (*Hint:* One way to answer this question is to determine the chemical name for each structure.)

(a)


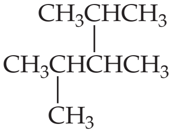
$CH_3\overset{CH_3}{\underset{CH_3}{C}}CH_2\underset{CH_3}{C}HCH_3$

(b)


$CH_3\overset{CH_3}{C}H\underset{CH_2CH_3}{C}H\overset{CH_3}{C}H_2$

(c)


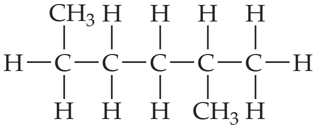
$CH_3\overset{CH_3}{C}H\underset{\underset{CH_3}{CHCH_3}}{C}HCH_3$

(d)


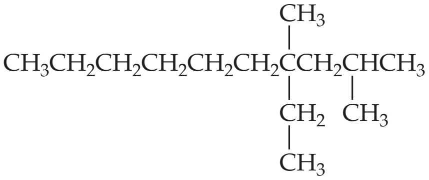
$CH_3\underset{CH_3}{C}H\overset{CH_3CHCH_3}{C}HCH_3$

2.88 True or false: isopentane and hexane are isomers.

2.89 Give the name or condensed structural formula, as appropriate.

(a)


$H-\overset{CH_3}{\underset{H}{C}}-\overset{H}{\underset{H}{C}}-\overset{H}{\underset{H}{C}}-\overset{H}{\underset{CH_3}{C}}-\overset{H}{\underset{H}{C}}-H$

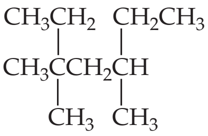
(b)


$CH_3CH_2CH_2CH_2CH_2CH_2\overset{CH_3}{\underset{CH_2CH_3}{C}}CH_2\underset{CH_3}{C}HCH_3$

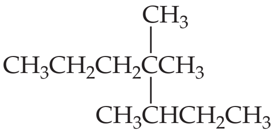
(**c**) 2-methylheptane

(**d**) 4-ethyl-2,3-dimethyloctane

2.90 Give the name or condensed structural formula, as appropriate.

(a)


$CH_3\overset{CH_3CH_2}{\underset{CH_3}{C}}CH_2\overset{CH_2CH_3}{\underset{CH_3}{C}}H$

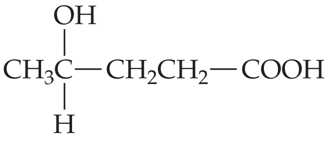
(b)


$CH_3CH_2CH_2\overset{CH_3}{\underset{CH_3CHCH_2CH_3}{C}}CH_3$

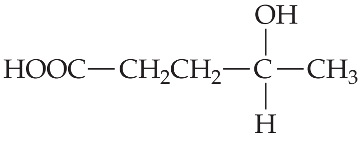
(**c**) 2,5,6-trimethylnonane

(**d**) 4-ethyl-5,6-dimethyldodecane

2.91 Two compounds are drawn below. Which statement is most correct? (**a**) These are two isomers of an alcohol. (**b**) These are two isomers of a carboxylic acid. (**c**) These are two isomers of a compound that is both an alcohol and a carboxylic acid. (**d**) These are two drawings of the same compound that is both an alcohol and a carboxylic acid.



$CH_3\overset{OH}{\underset{H}{C}}-CH_2CH_2-COOH$



$HOOC-CH_2CH_2-\overset{OH}{\underset{H}{C}}-CH_3$

2.92 How many isomers are there of *n*-pentanol?

Additional Exercises

2.93 Suppose a scientist repeats the Millikan oil-drop experiment but reports the charges on the drops using an unusual (and imaginary) unit called the *warmomb* (wa). The scientist obtains the following data for four of the drops:

Droplet	Calculated Charge (wa)
A	3.84×10^{-8}
B	4.80×10^{-8}
C	2.88×10^{-8}
D	8.64×10^{-8}

(**a**) If all the droplets were the same size, which would fall most slowly through the apparatus? (**b**) From these data, what is the best choice for the charge of the electron in warmombs? (**c**) Based on your answer to part (**b**), how many electrons are there on each of the droplets? (**d**) What is the conversion factor between warmombs and coulombs?

2.94 The natural abundance of ^{3}He is 0.000137%. (**a**) How many protons, neutrons, and electrons are in an atom of ^{3}He? (**b**) Based on the sum of the masses of their subatomic particles, which is expected to be more massive, an atom of ^{3}He or an atom of ^{3}H (which is also called *tritium*)? (**c**) Based on your answer to part (**b**), what would need to be the precision of a mass spectrometer that is able to differentiate between peaks that are due to $^{3}He^{+}$ and $^{3}H^{+}$?

2.95 Identify the element represented by each of the following symbols and give the number of protons and neutrons in each. (**a**) $^{74}_{33}X$ (**b**) $^{127}_{53}X$ (**c**) $^{152}_{63}X$ (**d**) $^{209}_{83}X$

2.96 The nucleus of ^{6}Li is a powerful absorber of neutrons. It exists in the naturally occurring metal to the extent of 7.5%. In the era of nuclear deterrence, large quantities of lithium were processed to remove ^{6}Li for use in hydrogen bomb production. The lithium metal remaining after removal of ^{6}Li was sold on the market. (**a**) What are the compositions of the nuclei of ^{6}Li and ^{7}Li? (**b**) The atomic masses of ^{6}Li and ^{7}Li are 6.015122 and 7.016004 amu, respectively. A sample of lithium depleted in the lighter isotope was found on analysis to contain 1.442% ^{6}Li. What is the average atomic weight of this sample of the metal?

2.97 The element oxygen has three naturally occurring isotopes, with 8, 9, and 10 neutrons in the nucleus, respectively. (**a**) Write the full chemical symbols for these three isotopes. (**b**) Which of these isotopes contains 10 electrons? (**c**) Oxygen-18 can be converted to fluorine-18 by a beam of high-energy protons. How many neutrons are in the nucleus of fluorine-18?

2.98 The element lead (Pb) consists of four naturally occurring isotopes with atomic masses 203.97302, 205.97444, 206.97587, and 207.97663 amu. The relative abundances of these four isotopes are 1.4, 24.1, 22.1, and 52.4%, respectively. From these data, calculate the atomic weight of lead.

2.99 Gallium (Ga) consists of two naturally occurring isotopes with masses of 68.926 and 70.925 amu. (**a**) How many protons and neutrons are in the nucleus of each isotope? Write the complete atomic symbol for each, showing the atomic number and mass number. (**b**) The average atomic mass of Ga is 69.72 amu. Calculate the abundance of each isotope.

2.100 There are two different isotopes of bromine atoms. Under normal conditions, elemental bromine consists of Br_2 molecules, and the mass of a Br_2 molecule is the sum of the masses of the two atoms in the molecule. The mass spectrum of Br_2 consists of three peaks:

m/z	Relative Peak Intensity
157.836	0.2569
159.834	0.4999
161.832	0.2431

(**a**) What is the origin of each peak (of what isotopes does each consist)? (**b**) What is the mass of each isotope? (**c**) Determine the average molecular mass of a Br_2 molecule. (**d**) Determine the average atomic mass of a bromine atom. (**e**) Calculate the abundances of the two isotopes.

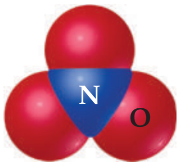
2.101 It is common in mass spectrometry to assume that the mass of a cation is the same as that of its parent atom. (**a**) Using data in Table 2.1, determine the number of significant figures that must be reported before the difference in masses of ^{1}H and $^{1}H^{+}$ is significant. (**b**) What percentage of the mass of an ^{1}H atom does the electron represent?

2.102 From the following list of elements—Ar, H, Ga, Al, Ca, Br, Ge, K, O—pick the one that best fits each description. Use each element only once. (**a**) an alkali metal (**b**) an alkaline earth metal (**c**) a noble gas (**d**) a halogen (**e**) a metalloid (**f**) a nonmetal listed in group 1A (**g**) a metal that forms a 3+ ion (**h**) a nonmetal that forms a 2− ion (**i**) an element that resembles aluminum

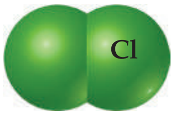
2.103 The first atoms of seaborgium (Sg) were identified in 1974. The longest-lived isotope of Sg has a mass number of 266. (**a**) How many protons, electrons, and neutrons are in an ^{266}Sg atom? (**b**) Atoms of Sg are very unstable, and it is therefore difficult to study this element's properties. Based on the position of Sg in the periodic table, what element should it most closely resemble in its chemical properties?

2.104 The explosion of an atomic bomb releases many radioactive isotopes, including strontium-90. Considering the location of strontium in the periodic table, suggest a reason for the fact that this isotope is particularly dangerous for human health.

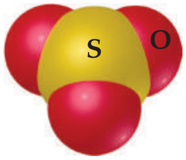
2.105 From the molecular structures shown here, identify the one that corresponds to each of the following species. (**a**) chlorine gas (**b**) propane (**c**) nitrate ion (**d**) sulfur trioxide (**e**) methyl chloride, CH_3Cl



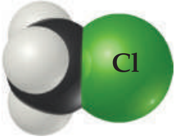
(i)



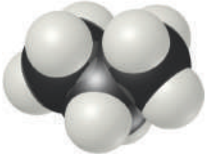
(ii)



(iii)



(iv)



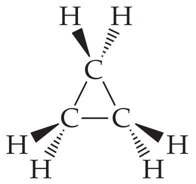
(v)

2.106 Name each of the following oxides. Assuming that the compounds are ionic, what charge is associated with the metallic element in each case? (**a**) NiO (**b**) MnO_2 (**c**) Cr_2O_3 (**d**) MoO_3

2.107 Fill in the blanks in the following table:

Cation	Anion	Formula	Name
			Lithium oxide
Fe^{2+}	PO_4^{3-}		
		$Al_2(SO_4)_3$	
			Copper(II) nitrate
Cr^{3+}	I^-		
		$MnClO_2$	
			Ammonium carbonate
			Zinc perchlorate

2.108 Instead of having three carbons in a row, the three carbons of the hydrocarbon cyclopropane form a ring, as shown in the following perspective drawing:



Cyclopropane was at one time used as an anesthetic, but its use was discontinued, in part because it is highly flammable. (**a**) What is the empirical formula of cyclopropane? (**b**) The three carbon atoms are necessarily in a plane. Is the entire molecule in a plane (flat)? (**c**) Can you use mass spectrometry to tell the difference between cyclopropane and propane, assuming the technique is reliable to 0.1 amu? (**d**) What change would you make to the structure shown to draw cyclopropanol? (**e**) How many isomers of cyclopropanol are there (ignore wedge positions for the purposes of this problem)?

2.109 Elements in the same group of the periodic table often form oxyanions with the same general formula. The anions are also named in a similar fashion. Based on these observations, suggest a chemical formula or name, as appropriate, for each of the following ions. (**a**) BrO_4^- (**b**) SeO_3^{2-} (**c**) arsenate ion (**d**) hydrogen tellurate ion

2.110 Carbonic acid occurs in carbonated beverages. When allowed to react with lithium hydroxide, it produces lithium carbonate. Lithium carbonate is used to treat depression and bipolar disorder. Write chemical formulas for carbonic acid, lithium hydroxide, and lithium carbonate.

2.111 Give the chemical names of each of the following familiar compounds. (**a**) NaCl (table salt) (**b**) $NaHCO_3$ (baking soda) (**c**) NaOCl (in many bleaches) (**d**) NaOH (caustic soda) (**e**) $(NH_4)_2CO_3$ (smelling salts) (**f**) $CaSO_4$ (plaster of Paris)

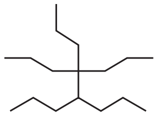
2.112 Many familiar substances have common, unsystematic names. For each of the following, give the correct systematic name. (**a**) salt-peter, KNO_3 (**b**) soda ash, Na_2CO_3 (**c**) lime, CaO (**d**) muriatic acid, HCl (**e**) Epsom salts, $MgSO_4$ (**f**) milk of magnesia, $Mg(OH)_2$

2.113 Because many ions and compounds have very similar names, there is great potential for confusing them. Write the correct chemical formulas to distinguish between (**a**) calcium sulfide and calcium hydrogen sulfide, (**b**) hydrobromic acid and bromic acid, (**c**) aluminum nitride and aluminum nitrite, (**d**) iron(II) oxide and iron(III) oxide, (**e**) ammonia and ammonium ion, (**f**) potassium sulfite and potassium bisulfite, (**g**) mercurous chloride and mercuric chloride, and (**h**) chloric acid and perchloric acid.

2.114 In what part of the atom does the strong nuclear force operate?

2.115 Chemists work with so many hydrocarbons that they abbreviate the structures with lines and vertices. Hexane, for instance, can be drawn as follows:

In this drawing, each end or vertex is a carbon atom, and it is assumed that sufficient hydrogens are added to each carbon to give each carbon 4 connections: $CH_3CH_2CH_2CH_2CH_2CH_3$. Moreover, the zig-zag nature of the drawing provides information about the relative angles of the carbons to each other. What, then, is the systematic name of the following compound?



3

CHEMICAL REACTIONS AND REACTION STOICHIOMETRY

▲ THESE STAINLESS STEEL REACTORS are where yeast-driven reactions occur that convert a sugar-rich aqueous solution called wort into beer.

In this chapter, we begin exploring chemical reactions. We describe how to predict the products of a few simple classes of reactions—combination, decomposition, and combustion reactions. We show that the number of atoms or molecules of a substance can be determined from its identity and the masses of the atoms that make up the substance. Building on that knowledge, we develop tools to predict how much of each product and reactant will be present at the end of a reaction from the amounts present before the reaction starts.

WHAT'S AHEAD

3.1 ▶ Chemical Equations Use chemical formulas to write equations representing chemical reactions.

3.2 ▶ Simple Patterns of Chemical Reactivity Examine some simple chemical reactions: *combination reactions, decomposition reactions*, and *combustion reactions*.

3.3 ▶ Formula Weights Use *formula weights* to obtain quantitative information from chemical formulas.

3.4 ▶ Avogadro's Number and the Mole Use chemical formulas to relate the mass of a substance to the numbers of atoms, molecules, or ions contained in the substance, a relationship that leads to the crucially important concept of the *mole*, defined as 6.02×10^{23} objects (atoms, molecules, ions, and so on).

3.5 ▶ Empirical Formulas from Analyses Apply the mole concept to determine chemical formulas from the masses of each element in a given quantity of a compound.

3.6 ▶ Quantitative Information from Balanced Equations Use the quantitative information inherent in chemical formulas and equations together with the mole concept to predict the amounts of substances consumed or produced in chemical reactions.

3.7 ▶ Limiting Reactants Recognize that one reactant may be used up before others in a chemical reaction. This is the *limiting reactant*. Once the limiting reactant is used up, the reaction stops, leaving some excess of the other starting materials.

3.1 | Chemical Equations

Learning Objectives

When you finish Section 3.1, you should be able to:

- Explain the law of conservation of mass in terms of the reactants and products of a chemical equation.
- Balance chemical equations by writing out the chemical formulas (and appropriate coefficients) of the reactants and products.

Much of the energy that we use in our daily lives, including transportation, comes from chemical reactions. In the internal combustion engine, gasoline and air react to produce energy, along with gaseous by-products (mostly carbon dioxide and water). These substances exit the tailpipes of vehicles—an issue that is central to discussions about climate change. Suppose we wanted to know how many molecules of CO_2 are produced by burning a certain amount of gasoline. The tools of chemistry we explore in this chapter enable us to accurately determine how many molecules of hydrocarbon and oxygen are consumed and how many molecules of by-products are generated.

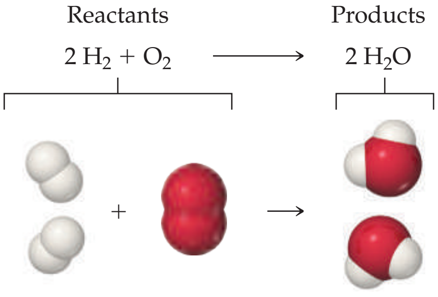
Stoichiometry (pronounced stoy-key-OM-uh-tree, roughly meaning "element measure" in Greek) is the area of study that examines the quantities of substances consumed and produced in chemical reactions. Chemists and chemical engineers use stoichiometry every day when running the reactions that drive the worldwide chemical industry. Stoichiometry is built on an understanding of atomic masses (Section 2.4), chemical formulas, and the **law of conservation of mass**. (Section 2.1) This important principle tells us that *atoms are neither created nor destroyed during a chemical reaction*. The changes that occur during any reaction merely rearrange the atoms. The same collection of atoms is present both before and after the reaction.

We represent chemical reactions by **chemical equations**. When the gas hydrogen (H_2) burns, for example, it reacts with oxygen (O_2) in the air to form water (H_2O). We write the chemical equation for this reaction as

$$2H_2 + O_2 \longrightarrow 2H_2O \qquad [3.1]$$

We read the + sign as "reacts with" and the arrow as "produces." The chemical formulas to the left of the arrow represent the starting substances, called **reactants**. The chemical formulas to the right of the arrow represent substances produced in the reaction, called **products**. The numbers in front of the formulas, called coefficients, indicate the relative numbers of molecules of each kind involved in the reaction. (As in algebraic equations, *the coefficient 1 is usually not written*.)

Because atoms are neither created nor destroyed in any reaction, a *balanced* chemical equation must have an equal number of atoms of each element on each side of the arrow. On the right side of Equation 3.1, for example, there are two molecules of H_2O, each composed of two atoms of hydrogen and one atom of oxygen (**Figure 3.1**). Thus, 2 H_2O (read "two molecules of water") contains $2 \times 2 = 4$ H atoms and $2 \times 1 = 2$ O atoms. Thus, *the number of atoms is obtained by multiplying each subscript in a chemical formula by the coefficient for the formula*. Because there are four H atoms and two O atoms on each side of the equation, the equation is balanced.



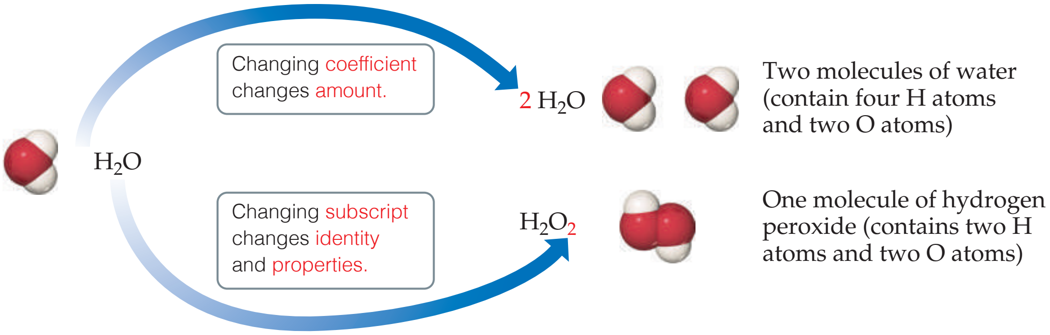
▲ **Figure 3.1** **A balanced chemical equation.**

Balancing Equations

Chemists write chemical equations to identify the reactants and products in a reaction. To determine the amount of product that can be made, or the amount of a reactant that is required, the equation needs to be *balanced* using the law of conservation of mass.

To construct a **balanced chemical equation**, we start by writing the formulas for the reactants on the left-hand side of the arrow and for the products on the right-hand side. We balance the equation by determining the coefficients that provide equal numbers of each type of atom on both sides of the equation. For most purposes, a balanced equation should contain the smallest possible whole-number coefficients.

In balancing an equation, you must distinguish between coefficients and subscripts. As **Figure 3.2** illustrates, changing a subscript in a formula—from H_2O to H_2O_2, for example—changes the identity of the substance. The substance H_2O_2, hydrogen peroxide, is quite different from the substance H_2O, water. *Never change subscripts when balancing an equation*. In contrast, placing a coefficient in front of a formula changes only the amount of the substance and not its identity. Thus, $2H_2O$ means two molecules of water, $3H_2O$ means three molecules of water, and so forth.



Changing coefficient changes amount.
H_2O
$2\ H_2O$
Two molecules of water (contain four H atoms and two O atoms)
Changing subscript changes identity and properties.
H_2O_2
One molecule of hydrogen peroxide (contains two H atoms and two O atoms)

◀ **Figure 3.2 The difference between changing subscripts and changing coefficients in chemical equations.**

A Step-by-Step Example of Balancing a Chemical Equation

To illustrate the process of balancing an equation, consider the reaction that occurs when methane (CH_4), the principal component of natural gas, burns in air to produce carbon dioxide gas (CO_2) and water vapor (H_2O) (**Figure 3.3**). Both products contain oxygen atoms that come from O_2 in the air. Thus, O_2 is a reactant, and the unbalanced equation is

$$CH_4 + O_2 \longrightarrow CO_2 + H_2O \quad \text{(unbalanced)} \qquad [3.2]$$

It is usually best to balance first those elements that occur in the fewest chemical formulas in the equation. In our example, C appears in only one reactant (CH_4) and one product (CO_2). The same is true for H (CH_4 and H_2O). Notice, however, that O appears in one reactant (O_2) and two products (CO_2 and H_2O). So, let's begin with C. Because one molecule of CH_4 contains the same number of C atoms as one molecule of CO_2, the coefficients for these substances *must* be the same in the balanced equation. Therefore, we start by choosing the coefficient 1 (unwritten) for both CH_4 and CO_2.

Next we focus on H. On the left side of the equation we have CH_4, which has four H atoms, whereas on the right side of the equation we have H_2O, containing two H atoms. To balance the H atoms in the equation we place the coefficient 2 in front of H_2O. Now there are four H atoms on each side of the equation:

$$CH_4 + O_2 \longrightarrow CO_2 + 2\,H_2O \quad \text{(unbalanced)} \qquad [3.3]$$

While the equation is now balanced with respect to hydrogen and carbon, it is not yet balanced for oxygen. Adding the coefficient 2 in front of O_2 balances the equation by giving four O atoms on each side [2×2 left, $2 + (2 \times 1)$ right]:

$$CH_4 + 2\,O_2 \longrightarrow CO_2 + 2\,H_2O \quad \text{(balanced)} \qquad [3.4]$$

The molecular view of the balanced equation is shown in **Figure 3.4**.

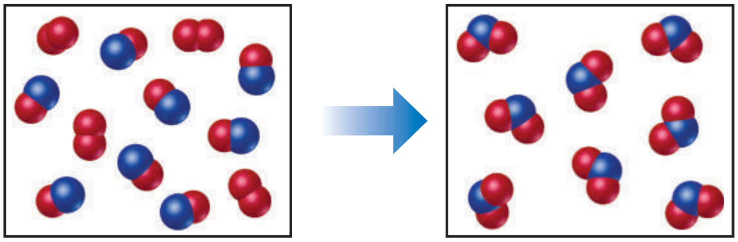
Sample Exercise 3.1

Interpreting and Balancing Chemical Equations

The following diagram represents a chemical reaction in which the red spheres are oxygen atoms and the blue spheres are nitrogen atoms. (**a**) Write the chemical formulas for the reactants and products. (**b**) Write a balanced equation for the reaction. (**c**) Is the diagram consistent with the law of conservation of mass?



SOLUTION

(**a**) The left box, which represents reactants, contains two kinds of molecules, those composed of two oxygen atoms (O_2) and those composed of one nitrogen atom and one oxygen atom (NO). The right box, which represents products, contains only one kind of molecule, which is composed of one nitrogen atom and two oxygen atoms (NO_2).

(**b**) The unbalanced chemical equation is

$$O_2 + NO \longrightarrow NO_2 \quad (\text{unbalanced})$$

An inventory of atoms on each side of the equation shows that there are one N and three O on the left side of the arrow and one N and two O on the right. To balance O, we must increase the number of O atoms on the right while keeping the coefficients for NO and NO_2 equal. Sometimes a trial-and-error approach is required; we need to go back and forth several times from one side of an equation to the other, changing coefficients first on one side of the equation and then the other until it is balanced. In our present case, let's start by increasing the number of O atoms on the right side of the equation by placing the coefficient 2 in front of NO_2:

$$O_2 + NO \longrightarrow 2\,NO_2 \quad (\text{unbalanced})$$

Now the equation gives two N atoms and four O atoms on the right, so we go back to the left side. Placing the coefficient 2 in front of NO balances both N and O:

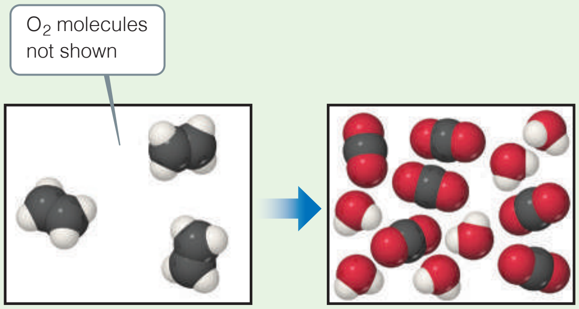
$$\underset{(2\,N,\,4\,O)}{O_2 + 2\,NO} \longrightarrow \underset{(2\,N,\,4\,O)}{2\,NO_2} \quad (\text{balanced})$$

(**c**) The reactants box contains four O_2 and eight NO. Thus, the molecular ratio is one O_2 for each two NO, as required by the balanced equation. The products box contains eight NO_2, which means the number of NO_2 product molecules equals the number of NO reactant molecules, as the balanced equation requires.

There are eight N atoms in the eight NO molecules in the reactants box. There are also $4 \times 2 = 8$ O atoms in the O_2 molecules and 8 O atoms in the NO molecules, giving a total of 16 O atoms. In the products box, we find eight NO_2 molecules, which contain eight N atoms and $8 \times 2 = 16$ O atoms. Because there are equal numbers of N and O atoms in the two boxes, the drawing is consistent with the law of conservation of mass.

▶ Practice Exercise

In the following diagram, the white spheres represent hydrogen atoms, the black spheres carbon atoms, and the red spheres oxygen atoms.



In this reaction, there are two reactants, ethylene, C_2H_4, which is shown, and oxygen, O_2, which is not shown, and two products, CO_2 and H_2O, both of which are shown. (**a**) Write a balanced chemical equation for the reaction. (**b**) How many O_2 molecules should be shown in the left (reactants) box?

Indicating the States of Reactants and Products

Symbols indicating the physical state of each reactant and product are often shown in chemical equations. We use the symbols (*g*), (*l*), (*s*), and (*aq*) for substances that are gases, liquids, solids, and dissolved in aqueous (water) solution, respectively. Thus, Equation 3.4 can be written

$$CH_4(g) + 2\,O_2(g) \longrightarrow CO_2(g) + 2\,H_2O(g) \qquad [3.5]$$

Sometimes symbols that represent the conditions under which the reaction proceeds appear above or below the reaction arrow. One example that we present later in this chapter involves the symbol Δ (Greek uppercase delta); a delta above the reaction arrow indicates the addition of heat.

Sample Exercise 3.2
Balancing Chemical Equations

Balance the equation

$$Na(s) + H_2O(l) \longrightarrow NaOH(aq) + H_2(g)$$

SOLUTION

Begin by counting each kind of atom on the two sides of the arrow. There are one Na, one O, and two H atoms on the left side, and one Na, one O, and three H atoms on the right. The Na and O atoms are currently balanced, but the number of H atoms is not. To increase the number of H atoms on the left, let's try placing the coefficient 2 in front of H_2O:

$$Na(s) + 2\,H_2O(l) \longrightarrow NaOH(aq) + H_2(g)$$

Although beginning this way does not balance H, it does increase the number of reactant H atoms, which we need to do. (Also, adding the coefficient 2 on H_2O unbalances O, but we will take care of that later.) Now that we have $2\,H_2O$ on the left, we balance H by putting the coefficient 2 in front of NaOH:

$$Na(s) + 2\,H_2O(l) \longrightarrow 2\,NaOH(aq) + H_2(g)$$

Balancing H in this way brings O into balance, but now Na is unbalanced, with one Na on the left and two on the right. To rebalance Na, we put the coefficient 2 in front of the reactant:

$$2\,Na(s) + 2\,H_2O(l) \longrightarrow 2\,NaOH(aq) + H_2(g)$$

We now have two Na atoms, four H atoms, and two O atoms on each side. The equation is balanced.

Comment Notice that we moved back and forth, placing a coefficient in front of H_2O, then NaOH, and finally Na. In balancing equations, we often find ourselves following this pattern of moving back and forth from one side of the arrow to the other, placing coefficients first in front of a formula on one side and then in front of a formula on the other side until the equation is balanced. You can always tell if you have balanced your equation correctly by checking that the number of atoms of each element is the same on the two sides of the arrow and that you've chosen the smallest set of coefficients that balances the equation.

▶ Practice Exercise

Balance these equations by providing the missing coefficients:

(a) $\_\_Fe(s) + \_\_O_2(g) \longrightarrow \_\_Fe_2O_3(s)$

(b) $\_\_Al(s) + \_\_HCl(aq) \longrightarrow \_\_AlCl_3(aq) + \_\_H_2(g)$

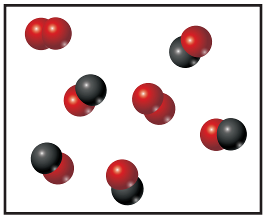
(c) $\_\_CaCO_3(s) + \_\_HCl(aq) \longrightarrow \_\_CaCl_2(aq) + \_\_CO_2(g) + \_\_H_2O(l)$

Self-Assessment Exercises

SAE 3.1 Carbon monoxide and oxygen react to form carbon dioxide according to the following balanced chemical equation:

$$2\,CO(g) + O_2(g) \longrightarrow 2\,CO_2(g)$$

If $CO(g)$ and $O_2(g)$ are combined in the ratio shown in the diagram below, where the black spheres represent carbon atoms and the red spheres represent oxygen atoms, which molecules will remain when the reaction is complete? **(a)** Only CO_2 molecules **(b)** CO_2 and CO molecules **(c)** CO_2 and O_2 molecules **(d)** CO and O_2 molecules



SAE 3.2 The unbalanced equation for the reaction between scandium metal and hydrochloric acid is:

$$\_\_\_Sc(s) + \_\_\_HCl(aq) \longrightarrow \_\_\_ScCl_3(aq) + \_\_\_H_2(g)$$

Once this equation is balanced with the smallest set of integer coefficients, what is the value of the coefficient in front of $HCl(aq)$? **(a)** 1 **(b)** 3 **(c)** 6 **(d)** 12

SAE 3.3 Sodium hydroxide and sodium metal react to form sodium oxide and hydrogen. Which of the following balanced equations represents this reaction?

(a) $NaOH(s) + Na(s) \longrightarrow Na_2O(s) + H_2(g)$

(b) $NaOH_2(s) + Na(s) \longrightarrow Na_2O(s) + H_2(g)$

(c) $2\,NaOH(s) + 2\,Na(s) \longrightarrow 2\,Na_2O(s) + H_2(g)$

(d) $NaOH(s) + Na(s) \longrightarrow Na_2O(s) + H(g)$

3.2 | Simple Patterns of Chemical Reactivity

Learning Objectives

When you finish Section 3.2, you should be able to:

- Identify combination reactions and predict their reaction products.
- Identify decomposition reactions and predict their reaction products.
- Identify combustion reactions and predict their reaction products.

One of the great triumphs of chemistry over the last hundred years is the development of fertilizers that enable us to feed the world. Ammonia, NH_3, is one of the principal chemicals farmers use to increase crop yield. The industrial process that is used to convert the elements nitrogen and hydrogen into ammonia, $N_2(g) + 3H_2(g) \rightarrow 2NH_3(g)$, may be a simple reaction, but it is one of the most important chemical reactions in the world. In this section, we introduce three broad classes of chemical reactions, including the combination reaction between nitrogen and hydrogen.

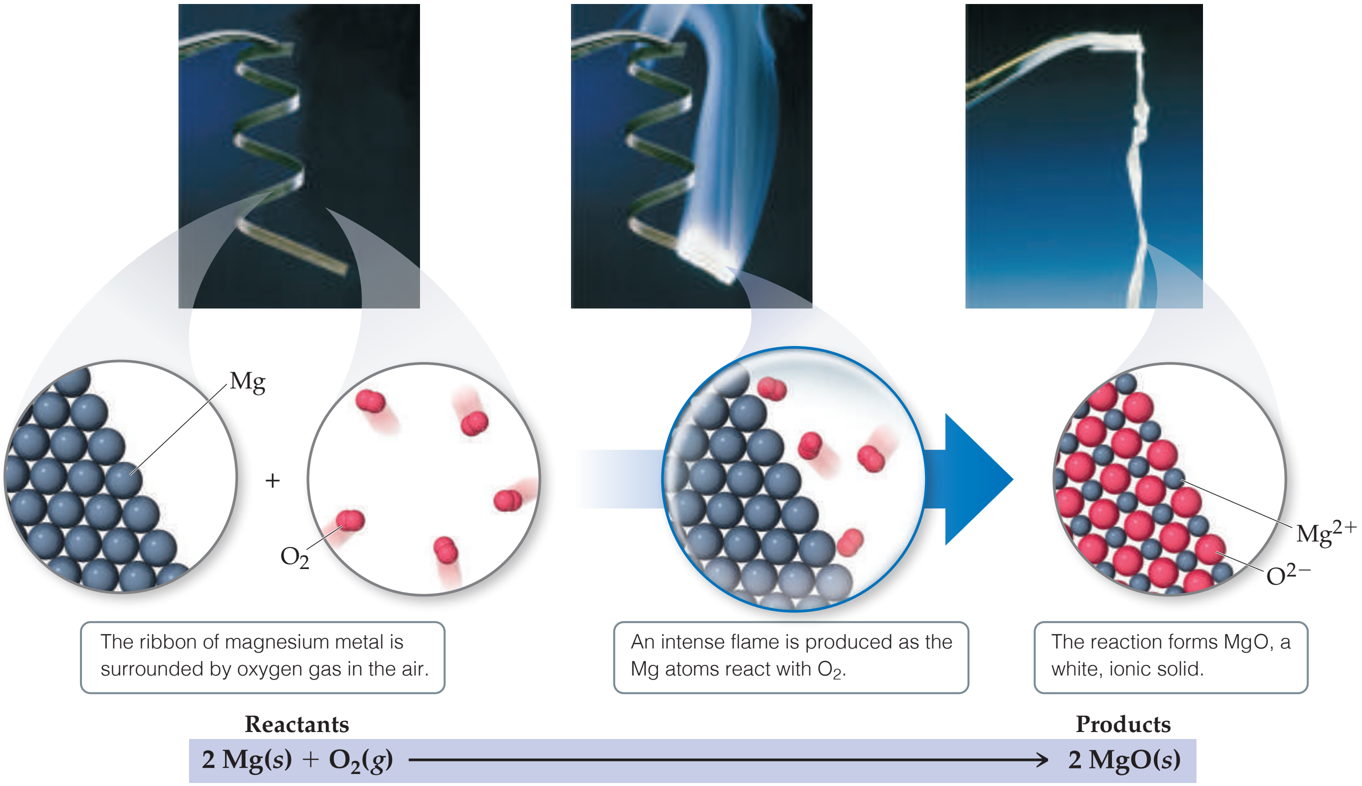
Combination and Decomposition Reactions

In **combination reactions**, two or more substances react to form one product (**Table 3.1**). For example, magnesium metal burns brilliantly in air to produce magnesium oxide (**Figure 3.5**):

$$2\,\mathrm{Mg}(s) + \mathrm{O_2}(g) \longrightarrow 2\,\mathrm{MgO}(s) \qquad [3.6]$$

TABLE 3.1 Combination and Decomposition Reactions

Combination Reactions	
$A + B \longrightarrow C$	Two or more reactants combine to form a single product. Many elements react with one another in this fashion to form compounds.
$C(s) + O_2(g) \longrightarrow CO_2(g)$	
$N_2(g) + 3\,H_2(g) \longrightarrow 2\,NH_3(g)$	
$CaO(s) + H_2O(l) \longrightarrow Ca(OH)_2(aq)$	
Decomposition Reactions	
$C \longrightarrow A + B$	A single reactant breaks apart to form two or more substances. Many compounds react this way when heated.
$2\,KClO_3(s) \longrightarrow 2\,KCl(s) + 3\,O_2(g)$	
$PbCO_3(s) \longrightarrow PbO(s) + CO_2(g)$	
$Cu(OH)_2(s) \longrightarrow CuO(s) + H_2O(g)$	



The ribbon of magnesium metal is surrounded by oxygen gas in the air.

An intense flame is produced as the Mg atoms react with O_2.

The reaction forms MgO, a white, ionic solid.

▲ **Figure 3.5 The combustion of magnesium metal in air is a combination reaction.**

This reaction is used to produce the bright flame generated by flares and some fireworks.

A combination reaction between a metal and a nonmetal, as in Equation 3.6, produces an ionic solid. Recall that the formula of an ionic compound can be determined from the charges of its ions. (Section 2.7) When magnesium reacts with oxygen, the magnesium loses electrons and forms the magnesium ion, Mg^{2+}. The oxygen gains electrons and forms the oxide ion, O^{2-}. Thus, the reaction product is MgO.

You should be able to recognize when a reaction is a combination reaction and to predict the products when the reactants are a metal and a nonmetal. Other examples of combination reactions include the formation of small gaseous molecules such as CO_2 and NH_3 from their elements, and the reaction of calcium oxide with water to produce calcium hydroxide:

$$C(s) + O_2(g) \longrightarrow CO_2(g) \qquad [3.7]$$

$$N_2(g) + 3H_2(g) \longrightarrow 2NH_3(g) \qquad [3.8]$$

$$CaO(s) + H_2O(l) \longrightarrow Ca(OH)_2(aq) \qquad [3.9]$$

In a **decomposition reaction**, one substance undergoes a reaction to produce two or more other substances (Table 3.1). For example, many metal carbonates decompose to form metal oxides and carbon dioxide when heated:

$$CaCO_3(s) \xrightarrow{\Delta} CaO(s) + CO_2(g) \qquad [3.10]$$

Decomposition of $CaCO_3$ is an important commercial process. Limestone or seashells, which are both primarily $CaCO_3$, are heated to prepare CaO, known as lime or quicklime. Tens of millions of tons of CaO are used in the United States each year in the production of glass and cement, in metallurgy where it is used to isolate the metals from their ores, and in steel manufacturing where it is used to remove impurities.

The decomposition of sodium azide (NaN_3) rapidly generates $N_2(g)$, and so this reaction is used to inflate safety air bags in automobiles (**Figure 3.6**):

$$2NaN_3(s) \longrightarrow 2Na(s) + 3N_2(g) \qquad [3.11]$$

The system is designed so that an impact ignites a detonator cap, which in turn causes NaN_3 to decompose explosively. A small quantity of NaN_3 (about 100 g) forms a large quantity of N_2 gas (about 50 L).

▲ Figure 3.6 Decomposition of sodium azide, $NaN_3(s)$, produces $N_2(g)$ that inflates air bags in automobiles.

CHEMISTRY AND SUSTAINABILITY Cement and CO_2 Emissions

Cement is produced on a scale that exceeds any other industrial material, approximately 4 billion metric tons per year. On a per mass basis, only water is consumed by society in larger quantities. Much of the cement is used as the binder in concrete, a composite of sand and gravel surrounded by a polymeric matrix containing hydrated oxides of calcium, silicon, aluminum, and iron. Cement has been used as a building material since Roman times, the Parthenon in Rome being one surviving example, but since 1950 the annual production of cement has increased more than 30-fold. This is a much faster rise than the approximate tripling of the world population that has occurred over the same period.

Five elements—oxygen, silicon, aluminum, iron, and calcium—account for more than 91% of Earth's crust. That cement is made primarily from these same five elements makes it possible to produce large volumes at a low cost, using local raw materials. In the most common type of cement, called Portland cement, calcium oxide accounts for 63% of the composition. The calcium oxide is obtained by heating limestone, which decomposes in what might be society's most important decomposition reaction, $CaCO_3(s) \longrightarrow CaO(s) + CO_2(g)$ (Equation 3.10). To drive the decomposition of $CaCO_3$ and trigger reactions between CaO and the oxides of Si, Al, and Fe, which mostly come from clays, the starting materials must be heated to temperatures near 1450 °C. Once this step is complete, the mixture is cooled and pulverized. The mixture at this point is called clinker, and it contains a number of oxides such as Ca_3SiO_5, Cs_2SiO_4, $Ca_3Al_2O_6$, and Ca_2AlFeO_5. To complete the production process, a small amount of $CaSO_4 \cdot 2H_2O$ (gypsum) is added, and the solid is ground to a fine powder. When this powder is mixed with water, insoluble hydrate phases form around the larger aggregates that make up concrete, and the composite cures into a strong, durable structural material as the excess water evaporates.

There can be no argument that cement plays an outsized role in modern society; unfortunately, it also makes a surprisingly large contribution to global carbon dioxide emissions. It is estimated that approximately 8% of all human-made CO_2 emissions come from the manufacture of cement. Approximately 40% of these emissions come from the fuel consumed to heat the raw materials to such a high temperature, with the remainder coming from the liberation of CO_2 in the decomposition of limestone. Even if sources of renewable energy were tapped to provide all the energy needed to produce cement, there is no easy way to eliminate the CO_2 emissions that emanate from the use of limestone. Strategies that involve transitioning to cements that have lower calcium contents and/or formulations that improve the binding strength of cement, thereby reducing the percentage of cement in concrete, can help reduce emissions. However, to reduce CO_2 emissions to near zero will likely require capturing the CO_2 that is produced and either storing it or using it for other purposes.

Sample Exercise 3.3

Writing Balanced Equations for Combination and Decomposition Reactions

Write a balanced equation for (**a**) the combination reaction between lithium metal and fluorine gas and (**b**) the decomposition reaction that occurs when solid barium carbonate is heated (two products form, a solid and a gas).

SOLUTION

(**a**) With the exception of mercury, all metals are solids at room temperature. Fluorine occurs as a diatomic molecule. Thus, the reactants are $Li(s)$ and $F_2(g)$. The product will be composed of a metal and a nonmetal, so we expect it to be an ionic solid. Lithium ions have a 1+ charge, Li^+, whereas fluoride ions have a 1− charge, F^-. Thus, the chemical formula for the product is LiF. The balanced chemical equation is

$$2\,Li(s) + F_2(g) \longrightarrow 2\,LiF(s)$$

(**b**) The chemical formula for barium carbonate is $BaCO_3$. As mentioned, many metal carbonates decompose to metal oxides and carbon dioxide when heated. In Equation 3.10, for example, $CaCO_3$ decomposes to form CaO and CO_2. Thus, we expect $BaCO_3$ to decompose to BaO and CO_2. Barium and calcium are both in group 2A in the periodic table, which further suggests they react in the same way:

$$BaCO_3(s) \longrightarrow BaO(s) + CO_2(g)$$

Practice Exercise

Write a balanced equation for (**a**) solid mercury(II) sulfide decomposing into its component elements when heated and (**b**) aluminum metal combining with oxygen in the air.

Combustion Reactions

Combustion reactions are rapid reactions that produce a flame. Most combustion reactions we observe involve O_2 from air as a reactant. The combustion of hydrocarbons (compounds that contain only carbon and hydrogen) in air is a major energy-producing process in our world. (Section 2.9)

Hydrocarbons combusted in air react with O_2 to form CO_2 and H_2O.* The number of molecules of O_2 required and the number of molecules of CO_2 and H_2O formed depend on the composition of the hydrocarbon, which acts as the fuel in the reaction. For example, the combustion of propane (C_3H_8, **Figure 3.7**), a gas used for cooking and home heating, is described by the equation

$$C_3H_8(g) + 5\,O_2(g) \longrightarrow 3\,CO_2(g) + 4\,H_2O(g) \qquad [3.12]$$

The state of the water in this reaction, $H_2O(g)$ or $H_2O(l)$ depends on the reaction conditions. In this case, $H_2O(g)$ is formed as the high-temperature flame burns in air.

Millions of compounds are made only of carbon, hydrogen, and oxygen. Notable classes of such molecules are sugars like sucrose ($C_{12}H_{22}O_{11}$) and alcohols like methanol (CH_3OH). Combustion of these oxygen-containing derivatives of hydrocarbons in air also produces CO_2, H_2O, and energy. Many of the substances that function as energy sources in metabolism, such as the sugar glucose ($C_6H_{12}O_6$), react with O_2 to ultimately form CO_2 and H_2O. In our bodies, however, the reactions take place in a series of intermediate steps that occur at body temperature. These reactions are called *oxidation reactions* rather than combustion reactions.

Go Figure

Does this reaction produce or consume thermal energy (heat)?

PROPANE FUEL

▲ **Figure 3.7** **Propane burning in air.** Liquid propane in the tank, C_3H_8, vaporizes and mixes with air as it escapes through the nozzle. The combustion reaction of C_3H_8 and O_2 produces a blue flame.

Sample Exercise 3.4

Writing Balanced Equations for Combustion Reactions

Write the balanced equation for the reaction that occurs when methanol, $CH_3OH(l)$, is burned in air.

SOLUTION

When any compound containing C, H, and O is combusted, it reacts with the $O_2(g)$ in air to produce $CO_2(g)$ and $H_2O(g)$. Thus, the unbalanced equation is

$$CH_3OH(l) + O_2(g) \longrightarrow CO_2(g) + H_2O(g)$$

The C atoms are balanced, one on each side of the arrow. Because CH_3OH has four H atoms, we place the coefficient 2 in front of H_2O to balance the H atoms:

$$CH_3OH(l) + O_2(g) \longrightarrow CO_2(g) + 2\,H_2O(g)$$

---

*When an insufficient quantity of O_2 is present, carbon monoxide (CO) is produced along with CO_2; this is called incomplete combustion. If the quantity of O_2 is severely restricted, the fine particles of carbon we call soot are produced. Complete combustion produces only CO_2 and H_2O. Unless stated to the contrary, we always take combustion to mean complete combustion.

Adding this coefficient balances H but gives four O atoms in the products. Because there are only three O atoms in the reactants, we are not finished. We can place the coefficient $\frac{3}{2}$ in front of O_2 to give four O atoms in the reactants ($\frac{3}{2} \times 2 = 3$ O atoms in $\frac{3}{2}O_2$):

$$CH_3OH(l) + \tfrac{3}{2}O_2(g) \longrightarrow CO_2(g) + 2H_2O(g)$$

Although this equation is balanced, it is not in its most conventional form because it contains a fractional coefficient. Multiplying through by 2 removes the fraction and keeps the equation balanced:

$$2CH_3OH(l) + 3O_2(g) \longrightarrow 2CO_2(g) + 4H_2O(g)$$

▶ Practice Exercise

Write the balanced equation for the reaction that occurs when ethanol, $C_2H_5OH(l)$, burns in air.

Self-Assessment Exercises

SAE 3.4 When Na and S undergo a combination reaction, what is the chemical formula of the product? **(a)** NaS **(b)** Na_2S **(c)** NaS_2 **(d)** Na_2S_3 **(e)** Na_3S_2

SAE 3.5 Using a process called electrolysis, we can decompose water into its constituent elements. Which of the following equations describes this reaction?

(a) $H_2O_2(l) \longrightarrow H_2(g) + O_2(g)$

(b) $H_2O(l) \longrightarrow H_2(g) + O_2(g)$

(c) $H_2O(l) \longrightarrow 2H(g) + O(g)$

(d) $2H_2O(l) \longrightarrow 2H_2(g) + O_2(g)$

SAE 3.6 What is the correct balanced equation for the reaction that occurs when diethyl ether, $CH_3CH_2OCH_2CH_3$, burns in air?

(a) $CH_3CH_2OCH_2CH_3(l) + 5O_2(g) \longrightarrow 4CO_2(g) + 5H_2O(g)$

(b) $CH_3CH_2OCH_2CH_3(l) + 6O_2(g) \longrightarrow 4CO_2(g) + 5H_2O(g)$

(c) $CH_3CH_2OCH_2CH_3(l) + 12O(g) \longrightarrow 4CO_2(g) + 5H_2O(g)$

(d) $2CH_3CH_2OCH_2CH_3(l) + 12O_2(g) \longrightarrow 8CO_2(g) + 10H_2O(g)$

3.3 | Formula Weights

Sulfuric acid, $H_2SO_4(l)$, is a common laboratory chemical that is used by the metric ton in the chemical industry. We can see from the molecular model in Figure 3.8 that one molecule of H_2SO_4 contains one sulfur atom, four oxygen atoms, and two hydrogen atoms. In the lab, we most commonly dispense milliliters of its aqueous solution, $H_2SO_4(aq)$. While the atomic ratios of sulfur, oxygen, and hydrogen may be fixed by the chemical formula, how do we know how many molecules of H_2SO_4 are present in a sample we encounter in the lab? That is the topic we begin to explore in this section.

Learning Objectives

When you finish Section 3.3, you should be able to:

- ▶ Calculate the formula weight of a substance from its empirical formula or its molecular weight from its molecular formula.
- ▶ Determine the elemental composition (by mass) of a compound from its empirical or molecular formula.

Formula and Molecular Weights

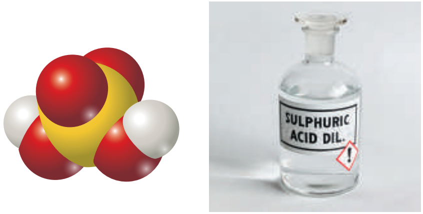
Although we cannot count individual atoms or molecules, we can indirectly determine their numbers if we know their masses. Therefore, we need to know more about the masses of substances. The **formula weight** (FW) of a substance is the sum of the atomic weights (AW) of the atoms in the chemical formula of the substance. Using atomic weights from the periodic table, we find, for example, that the formula weight of sulfuric acid, H_2SO_4, is 98.1 amu (atomic mass units):

$$\begin{aligned} \text{FW of } H_2SO_4 &= 2(\text{AW of H}) + (\text{AW of S}) + 4(\text{AW of O}) \\ &= 2(1.0\text{ amu}) + 32.1\text{ amu} + 4(16.0\text{ amu}) \\ &= 98.1\text{ amu} \end{aligned}$$

For convenience, we have rounded off the atomic weights to one decimal place, a practice we follow in most calculations in this book.

If the chemical formula is the chemical symbol of an element, such as Na, the formula weight equals the atomic weight of the element, in this case 23.0 amu. If the chemical formula is that of a molecule, the formula weight is also called the **molecular weight** (MW). The molecular weight of glucose ($C_6H_{12}O_6$), for example, is

$$\text{MW of } C_6H_{12}O_6 = 6(12.0\text{ amu}) + 12(1.0\text{ amu}) + 6(16.0\text{ amu}) = 180.0\text{ amu}$$



▲ **Figure 3.8 Sulfuric acid.** The sulfuric acid molecule, H_2SO_4, is represented here with yellow, red, and white spheres for sulfur, oxygen, and hydrogen, respectively. Also shown is a bottle of $H_2SO_4(aq)$ solution.

Because ionic substances exist as three-dimensional arrays of ions (see Figure 2.20), it is inappropriate to speak of *molecules* of these substances. Instead we use the empirical formula as the formula unit, and the formula weight of an ionic substance is determined by summing the atomic weights of the atoms in the empirical formula. For example, the formula unit of $CaCl_2$ consists of one Ca^{2+} ion and two Cl^- ions. Thus, the formula weight of $CaCl_2$ is

$$\text{FW of } CaCl_2 = 40.1 \text{ amu} + 2(35.5 \text{ amu}) = 111.1 \text{ amu}$$

Sample Exercise 3.5

Calculating Formula Weights

Calculate the formula weight of (**a**) sucrose, $C_{12}H_{22}O_{11}$ (table sugar); and (**b**) calcium nitrate, $Ca(NO_3)_2$.

SOLUTION

(**a**) By adding the atomic weights of the atoms in sucrose, we find the formula weight to be 342.0 amu:

$$\begin{aligned} 12 \text{ C atoms} &= 12(12.0 \text{ amu}) = 144.0 \text{ amu} \\ 22 \text{ H atoms} &= 22(1.0 \text{ amu}) = 22.0 \text{ amu} \\ 11 \text{ O atoms} &= 11(16.0 \text{ amu}) = \underline{176.0 \text{ amu}} \\ & \qquad\qquad\qquad\qquad 342.0 \text{ amu} \end{aligned}$$

(**b**) If a chemical formula has parentheses, the subscript outside the parentheses is a multiplier for all atoms inside. Thus, for $Ca(NO_3)_2$ we have

$$\begin{aligned} 1 \text{ Ca atom} &= 1(40.1 \text{ amu}) = 40.1 \text{ amu} \\ 2 \text{ N atoms} &= 2(14.0 \text{ amu}) = 28.0 \text{ amu} \\ 6 \text{ O atoms} &= 6(16.0 \text{ amu}) = \underline{96.0 \text{ amu}} \\ & \qquad\qquad\qquad\qquad 164.1 \text{ amu} \end{aligned}$$

Practice Exercise

Calculate the formula weight of (**a**) $Al(OH)_3$, (**b**) CH_3OH, and (**c**) TaON.

Percentage Composition from Chemical Formulas

Chemists must sometimes calculate the *percentage composition* of a compound—that is, the percentage by mass contributed by each element in the substance. Let's say you are a forensic chemist, working in a crime lab, and your colleagues find a mysterious white powder at a crime scene. Is it salt, sugar, methamphetamine, cocaine, or something else?

One way to determine the identity of a substance is to measure its **elemental composition** and compare it to the calculated elemental compositions of possible candidate substances. The calculation depends on the formula weight of the substance, the atomic weight of the element of interest, and the number of atoms of that element in the chemical formula:

$$\begin{matrix}\text{\% mass composition} \\ \text{of element}\end{matrix} = \frac{\begin{pmatrix}\text{number of atoms} \\ \text{of element}\end{pmatrix}\begin{pmatrix}\text{atomic weight} \\ \text{of element}\end{pmatrix}}{\text{formula weight of substance}} \times 100\% \qquad [3.13]$$

Sample Exercise 3.6

Calculating Percentage Composition

Calculate the percentage of carbon, hydrogen, and oxygen (by mass) in sucrose, $C_{12}H_{22}O_{11}$.

SOLUTION

Analyze We are given a chemical formula and asked to calculate the percentage by mass of each element.

Plan We use Equation 3.13, obtaining our atomic weights from a periodic table. We know the denominator in Equation 3.13, the formula weight of $C_{12}H_{22}O_{11}$, from Sample Exercise 3.5. We must use that value in three calculations, one for each element.

Solve

$$\text{\% carbon} = \frac{(12)(12.0 \, \cancel{\text{amu}})}{342.0 \, \cancel{\text{amu}}} \times 100\% = 42.1\%$$

$$\text{\% hydrogen} = \frac{(22)(1.0 \, \cancel{\text{amu}})}{342.0 \, \cancel{\text{amu}}} \times 100\% = 6.4\%$$

$$\text{\% oxygen} = \frac{(11)(16.0 \, \cancel{\text{amu}})}{342.0 \, \cancel{\text{amu}}} \times 100\% = 51.5\%$$

Check Our calculated percentages must add up to 100%, which they do. We could have used more significant figures for our atomic weights, giving more significant figures for our percentage composition, but we have adhered to our suggested guideline of rounding atomic weights to one digit beyond the decimal point.

Practice Exercise

Calculate the percentage of potassium, by mass, in K_2PtCl_6.

The sum of all the mass percentages of each element in the compound must add up to 100%.

As an example, let's calculate the mass percentage of sulfur in sulfuric acid. Based on the molecular formula, we can see that for each H_2SO_4 molecule, one atom out of seven is sulfur. But that doesn't mean that 1/7 of the mass of the compound is sulfur, because the atoms that make up the molecule have different masses. Using Equation 3.13:

$$\% \text{ sulfur in } H_2SO_4 = \frac{(1)(32.1\,\text{amu})}{98.1\,\text{amu}} = 32.7\%$$

we find that almost a third of the mass of any sample of pure H_2SO_4 is due to sulfur.

STRATEGIES FOR SUCCESS Problem Solving

Practice is the key to success in solving problems. As you practice, you can improve your skills by following these steps:

1. **Analyze the problem.** Read the problem carefully. What does it say? Draw a picture or diagram that will help you to visualize the problem. Write down both the data you are given and the quantity you need to obtain (the unknown).
2. **Develop a plan for solving the problem.** Consider a possible path between the given information and the unknown. What principles or equations relate the known data to the unknown? Recognize that some data may not be given explicitly in the problem; you may be expected to know certain quantities or to look them up in tables (such as atomic weights). Recognize also that your plan may involve either a single step or a series of steps with intermediate answers.
3. **Solve the problem.** Use the known information and suitable equations or relationships to solve for the unknown. Dimensional analysis (Section 1.7) is a useful tool for solving a great number of problems. Be careful with significant figures, signs, and units.
4. **Check the solution.** Read the problem again to make sure you have found all the solutions asked for in the problem. Does your answer make sense? That is, is the answer outrageously large or small, or is it in the ballpark? Finally, are the units and significant figures correct?

Self-Assessment Exercises

SAE 3.7 Which of the following is the correct formula weight for copper(II) chloride? (**a**) 99.0 amu (**b**) 134.5 amu (**c**) 162.6 amu (**d**) 233.5 amu

SAE 3.8 What is the formula weight of hypochlorous acid? (**a**) 36.5 amu (**b**) 52.5 amu (**c**) 67.4 amu (**d**) 100.5 amu

SAE 3.9 What is the percentage of phosphorus, by mass, in calcium phosphate? (**a**) 70.3% (**b**) 61.2% (**c**) 22.9% (**d**) 20.0% (**e**) 10.0%

SAE 3.10 A mysterious white powder found at a crime scene is analyzed and found to contain 66.9 ± 0.5% carbon by mass. One of the investigators hypothesizes that the substance is cocaine, $C_{17}H_{21}NO_4$. What is the percent carbon, by mass, in cocaine? (**a**) 39.5% (**b**) 64.3% (**c**) 67.3% (**d**) 70.6%

3.4 | Avogadro's Number and the Mole

Even the smallest samples we deal with in the laboratory contain enormous numbers of atoms, ions, or molecules. For example, a teaspoon of water (about 5 mL) contains 2×10^{23} water molecules, a number so large it almost defies comprehension. Chemists therefore have devised a counting unit for describing large numbers of atoms or molecules.

In everyday life we use such familiar counting units as dozen (12 objects) and gross (144 objects). In chemistry the counting unit for numbers of atoms, ions, or molecules in a laboratory-sized sample is the *mole*, often abbreviated mol. One **mole** is the amount of matter that contains as many objects (atoms, molecules, or whatever other objects we are considering) as the number of atoms in exactly 12 g of isotopically pure ^{12}C. From experiments, scientists have determined this number to be 6.0221415×10^{23}, which we usually round to 6.02×10^{23}. Scientists call this value **Avogadro's number**, N_A, in honor of the Italian scientist Amedeo Avogadro (1776–1856), and it is often cited with units of reciprocal moles, $6.02 \times 10^{23}\,\text{mol}^{-1}$.* The unit (read as either "inverse mole" or "per

Learning Objectives

When you finish Section 3.4, you should be able to:

- ▶ Calculate the *molar mass* for a compound and relate this to its formula weight.
- ▶ Interconvert between grams, molecules, and moles of a substance.

---

*Avogadro's number is also referred to as the Avogadro constant. The latter term is the name adopted by agencies such as the National Institute of Standards and Technology (NIST), but Avogadro's number remains in widespread usage and is used in most places in this book.

mole") reminds us that there are 6.02×10^{23} objects per one mole. A mole of atoms, a mole of molecules, or a mole of anything else all contain Avogadro's number of objects:

$$1\text{ mol }^{12}\text{C atoms} = 6.02 \times 10^{23}\ ^{12}\text{C atoms}$$

$$1\text{ mol H}_2\text{O molecules} = 6.02 \times 10^{23}\text{ H}_2\text{O molecules}$$

$$1\text{ mol NO}_3^-\text{ ions} = 6.02 \times 10^{23}\text{ NO}_3^-\text{ ions}$$

Avogadro's number is so large that spreading 6.02×10^{23} marbles over Earth's surface would produce a layer about 3 miles thick. Avogadro's number of pennies placed side by side in a straight line would encircle Earth 300 trillion (3×10^{14}) times.

Sample Exercise 3.7

Estimating Numbers of Atoms

Without using a calculator, arrange these samples in order of increasing numbers of carbon atoms: 12 g ^{12}C, 1 mol C_2H_2, 9×10^{23} molecules of CO_2.

SOLUTION

Analyze We are given amounts of three substances expressed in grams, moles, and number of molecules, respectively, and are asked to arrange the samples in order of increasing numbers of C atoms.

Plan To determine the number of C atoms in each sample, we must convert 12 g ^{12}C, 1 mol C_2H_2 and 9×10^{23} molecules of CO_2 to numbers of C atoms. To make these conversions, we use the definition of mole and Avogadro's number.

Solve One mole is defined as the amount of matter that contains as many units of the matter as there are C atoms in exactly 12 g of ^{12}C. Thus, 12 g of ^{12}C contains 1 mol of C atoms $= 6.02 \times 10^{23}$ atoms.

One mol of C_2H_2 contains 6.02×10^{23} molecules. Because there are two C atoms in each molecule, this sample contains 12.04×10^{23} C atoms.

Because each CO_2 molecule contains one C atom, the CO_2 sample contains 9×10^{23} C atoms.

Hence, the order is 12 g ^{12}C (6×10^{23} atoms) $<$ 9×10^{23} CO_2 molecules (9×10^{23} C atoms) $<$ 1 mol C_2H_2 (12×10^{23} C atoms).

Check We can check our results by comparing numbers of moles of C atoms in the samples because the number of moles is proportional to the number of atoms. Thus, 12 g of ^{12}C is 1 mol C, 1 mol of C_2H_2 contains 2 mol C, and 9×10^{23} molecules of CO_2 contain 1.5 mol C, giving the same order as stated previously.

▶ Practice Exercise

Without using a calculator, arrange these samples in order of increasing numbers of O atoms: 1 mol H_2O, 1 mol CO_2, 3×10^{23} molecules O_2.

Molar Mass

A dozen is the same number, 12, whether we have a dozen eggs or a dozen elephants. A dozen eggs has considerably less mass, however, than a dozen elephants. Similarly, a mole is always the *same number* (6.02×10^{23}) but 1-mol samples of different substances have *different masses*. Compare, for example, 1 mol of ^{12}C and 1 mol of ^{24}Mg. A single ^{12}C atom has a mass of 12 amu, whereas a single ^{24}Mg atom is twice as massive, 24 amu (to two significant figures). Because a mole of anything always contains the same number of particles, a mole of ^{24}Mg must be twice as massive as a mole of ^{12}C. Because a mole of ^{12}C has a mass of 12 g (by definition), a mole of ^{24}Mg must have a mass of 24 g. This example illustrates a general rule relating the mass of an atom to the mass of Avogadro's number (1 mol) of these atoms: *The atomic weight of an element in atomic mass units is numerically equal to the mass in grams of 1 mol of that element*. For example (the symbol $\Rightarrow$ means "therefore"),

$$\text{Cl has an atomic weight of } 35.5\text{ amu} \Rightarrow 1\text{ mol Cl has a mass of } 35.5\text{ g}.$$

$$\text{Au has an atomic weight of } 197\text{ amu} \Rightarrow 1\text{ mol Au has a mass of } 197\text{ g}.$$

For other kinds of substances, the same numerical relationship exists between formula weight and mass of 1 mol of a substance:

$$\text{H}_2\text{O has a formula weight of } 18.0\text{ amu} \Rightarrow 1\text{ mol H}_2\text{O has a mass of } 18.0\text{ g (Figure 3.9)}.$$

$$\text{NaCl has a formula weight of } 58.5\text{ amu} \Rightarrow 1\text{ mol NaCl has a mass of } 58.5\text{ g}.$$

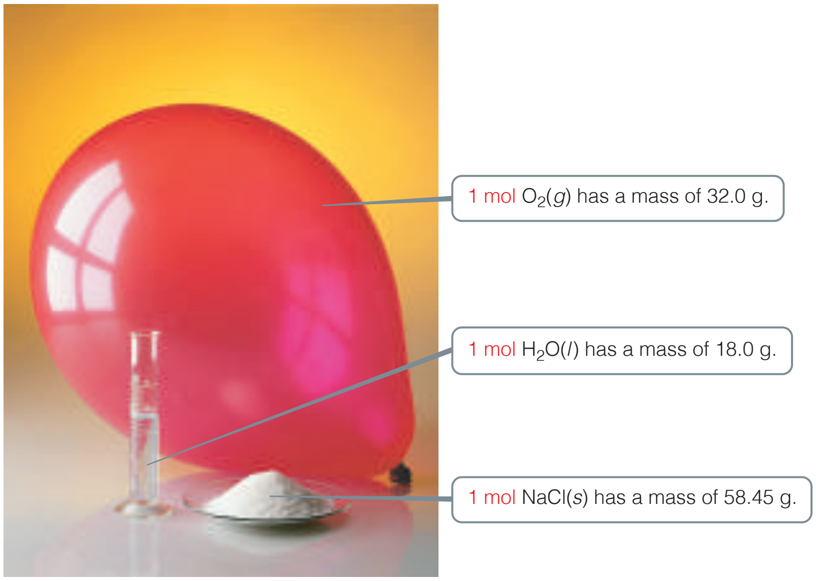
The mass in grams of one mole of a substance is called the **molar mass** of the substance. *The molar mass in grams per mole of any substance is numerically equal to its formula weight in atomic mass units*. For NaCl, for example, the formula weight is 58.5 amu and the molar mass is 58.5 g/mol. Mole relationships for several other substances are listed in **Table 3.2**, and **Figure 3.10** shows 1 mol quantities of three common substances.

The entries in Table 3.2 for N and N_2 point out the importance of stating the chemical form of a substance when using the mole concept. Suppose you read that 1 mol of nitrogen is produced in a particular reaction. You might interpret this statement to mean 1 mol of nitrogen atoms (14.0 g). Unless otherwise stated, however, what is probably meant is 1 mol of nitrogen molecules, N_2 (28.0 g), because N_2 is the most common chemical form of the element. To avoid ambiguity, it is important to state explicitly the chemical form being discussed. Using the chemical formula—N or N_2, for instance—avoids any confusion.

TABLE 3.2 Mole Relationships

Name of Substance	Formula	Formula Weight (amu)	Molar Mass (g/mol)	Number and Kind of Particles in One Mole
Atomic nitrogen	N	14.0	14.0	6.02×10^{23} N atoms
Molecular nitrogen or "dinitrogen"	N_2	28.0	28.0	6.02×10^{23} N_2 molecules $2(6.02 \times 10^{23})$ N atoms
Silver	Ag	107.9	107.9	6.02×10^{23} Ag atoms
Silver ions	Ag^+	107.9[a]	107.9	6.02×10^{23} Ag^+ ions
Barium chloride	$BaCl_2$	208.2	208.2	6.02×10^{23} $BaCl_2$ formula units 6.02×10^{23} Ba^{2+} ions $2(6.02 \times 10^{23})$ Cl^- ions

[a] Recall that the mass of an electron is more than 1800 times smaller than the masses of the proton and the neutron; thus, ions and atoms have essentially the same mass.

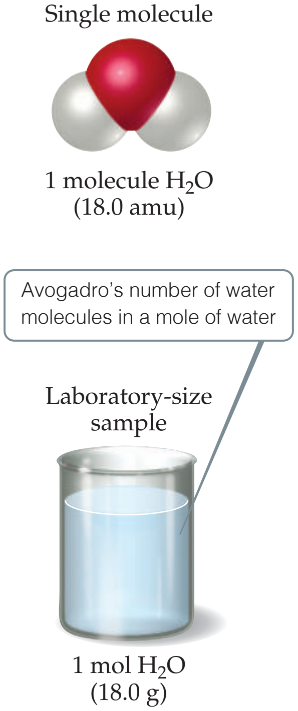


1 mol $O_2(g)$ has a mass of 32.0 g.
1 mol $H_2O(l)$ has a mass of 18.0 g.
1 mol NaCl(s) has a mass of 58.45 g.

▲ **Figure 3.10 One mole each of a solid (NaCl), a liquid (H_2O), and a gas (O_2).** In each case, the mass in grams of 1 mol—that is, the molar mass—is numerically equal to the formula weight in atomic mass units. Each of these samples contains 6.02×10^{23} formula units.

Go Figure

What number do you get if you divide the mass of 1 mol of water by the mass of 1 molecule of water?



▲ **Figure 3.9 Comparing the mass of 1 molecule and 1 mol of** H_2O. Both masses have the same number but different units (atomic mass units and grams). Expressing both masses in grams indicates their huge difference: 1 molecule of H_2O has a mass of 2.99×10^{-23} g, whereas 1 mol of H_2O has a mass of 18.0 g.

Sample Exercise 3.8

Calculating Molar Mass

What is the molar mass of glucose, $C_6H_{12}O_6$?

SOLUTION

Analyze We are given a chemical formula and asked to determine its molar mass.

Plan Because the molar mass of any substance is numerically equal to its formula weight, we first determine the formula weight of glucose by adding the atomic weights of its component atoms. The formula weight will have units of amu, whereas the molar mass has units of grams per mole (g/mol).

Solve Our first step is to determine the formula weight of glucose:

$$\begin{aligned} 6\text{ C atoms} &= 6(12.0\text{ amu}) = 72.0\text{ amu} \\ 12\text{ H atoms} &= 12(1.0\text{ amu}) = 12.0\text{ amu} \\ 6\text{ O atoms} &= 6(16.0\text{ amu}) = \underline{96.0\text{ amu}} \\ & \qquad\qquad\qquad\quad 180.0\text{ amu} \end{aligned}$$

Because glucose has a formula weight of 180.0 amu, 1 mol of this substance (6.02×10^{23} molecules) has a mass of 180.0 g. In other words, $C_6H_{12}O_6$ has a molar mass of 180.0 g/mol.

Continued

Check A molar mass below 250 seems reasonable based on the earlier examples we have encountered, and grams per mole is the appropriate unit for the molar mass.

▶ **Practice Exercise**

Calculate the molar mass of $Ca(NO_3)_2$.

Interconverting Masses, Moles and Numbers of Particles

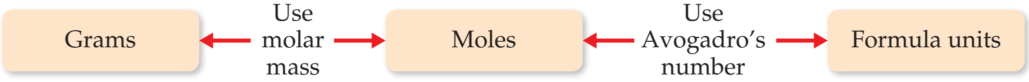
The mole concept provides the bridge between mass and number of particles (**Figure 3.11**). We can use this concept to relate the stoichiometries expressed in chemical equations to the amounts of chemicals used and produced in reactions. For example, let's calculate how many copper atoms are in an old copper penny. The penny has a mass of about 3 grams, and for simplicity we'll assume it is pure copper:

$$\text{Cu atoms} = (3\ \text{g}\ \cancel{\text{Cu}})\left(\frac{1\ \cancel{\text{mol Cu}}}{63.5\ \cancel{\text{g Cu}}}\right)\left(\frac{6.02 \times 10^{23}\ \text{Cu atoms}}{1\ \cancel{\text{mol Cu}}}\right)$$
$$= 3 \times 10^{22}\ \text{Cu atoms}$$

We have rounded our answer to one significant figure because we used only one significant figure for the mass of the penny. Notice how dimensional analysis provides a straightforward route from grams to numbers of atoms. The molar mass is used as a conversion factor to convert grams to moles; then Avogadro's number is used to convert moles to atoms (Figure 3.11). Notice also that our answer is a very large number. Any time you calculate the number of atoms, molecules, or ions in an ordinary sample of matter, you can expect the answer to be very large. In contrast, the number of moles in a sample will usually be small, often less than 1.

Go Figure

What units would you assign to "molar mass" and "Avogadro's number" in this diagram?



▲ **Figure 3.11 Procedure for interconverting mass and number of formula units.** The number of moles of the substance is central to the calculation. Thus, the mole concept can be thought of as the bridge between the mass of a sample in grams and the number of formula units contained in the sample.

Sample Exercise 3.9

Converting Grams to Moles

Calculate the number of moles of glucose ($C_6H_{12}O_6$) in a 5.380-g sample.

SOLUTION

Analyze We are given the number of grams of a substance and its chemical formula and asked to calculate the number of moles.

Plan The molar mass of a substance provides the factor for converting grams to moles. The molar mass of $C_6H_{12}O_6$ is 180.0 g/mol (Sample Exercise 3.8).

Solve Using 1 mol $C_6H_{12}O_6$ = 180.0 g $C_6H_{12}O_6$ to write the appropriate conversion factor, we have

$$\text{Moles } C_6H_{12}O_6 = (5.380\ \cancel{\text{g } C_6H_{12}O_6})\left(\frac{1\ \text{mol } C_6H_{12}O_6}{180.0\ \cancel{\text{g } C_6H_{12}O_6}}\right)$$
$$= 0.02989\ \text{mol } C_6H_{12}O_6$$

Check Because 5.380 g is less than the molar mass, an answer less than one mole is reasonable. The unit mol is appropriate. The original data had four significant figures, so our answer has four significant figures.

▶ **Practice Exercise**

A 508-g sample of sodium bicarbonate ($NaHCO_3$) contains how many moles of sodium bicarbonate?

Self-Assessment Exercises

SAE 3.11 Two beakers contain equal masses of CCl_4 and NH_3, respectively. Which beaker contains more molecules? (**a**) The beaker with CCl_4 (**b**) The beaker with NH_3 (**c**) The two beakers contain the same number of molecules

SAE 3.12 An aqueous solution of caffeine contains 0.186 mol of caffeine. When the caffeine is separated from the rest of the solution, it is found to have a mass of 36.1 g. What is the molar mass of caffeine? (**a**) 0.00515 g/mol (**b**) 36.1 g/mol (**c**) 186 g/mol (**d**) 194 g/mol

3.5 | Empirical Formulas from Analyses

The empirical formula for a substance tells us the relative number of atoms of each element in the substance. (Section 2.6) The empirical formula H_2O shows that water contains two H atoms for each O atom. This ratio also applies on the molar level: 1 mol of H_2O contains 2 mol of H atoms and 1 mol of O atoms. Conversely, *the ratio of the numbers of moles of all elements in a compound gives the subscripts in the compound's empirical formula*. Thus, the mole concept provides a way of calculating empirical formulas from experimental data.

Learning Objectives

When you finish Section 3.5, you should be able to:

- Calculate the empirical formula of a compound from the mass percentages of the elements that make up the compound.
- Determine the molecular formula of a molecular compound given its empirical formula and molecular weight.
- Determine the empirical formula of a compound containing only carbon, hydrogen, and oxygen from the results of combustion analysis.

Mercury and chlorine combine to form a compound that is measured to be 74.0% mercury and 26.0% chlorine by mass. Thus, if we had a 100.0-g sample of the compound, it would contain 74.0 g of mercury and 26.0 g of chlorine. (Samples of any size can be used in problems of this type, but we will generally use 100.0 g to simplify the calculation of mass from percentage.) Using atomic weights to get molar masses, we calculate the number of moles of each element in the sample:

$$(74.0\ \cancel{\text{g Hg}})\left(\frac{1\text{ mol Hg}}{200.6\ \cancel{\text{g Hg}}}\right) = 0.369\text{ mol Hg}$$

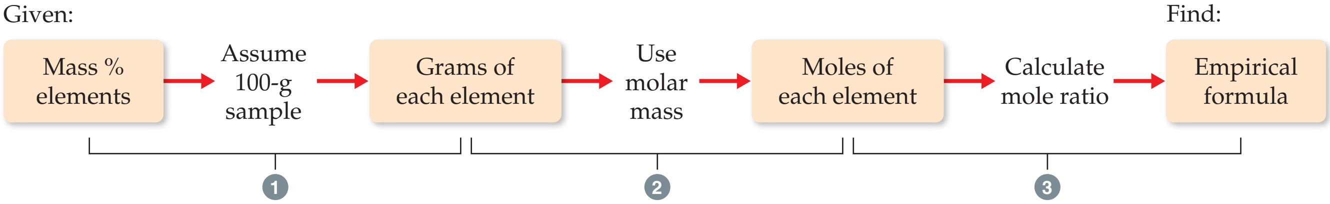
$$(26.0\ \cancel{\text{g Cl}})\left(\frac{1\text{ mol Cl}}{35.5\ \cancel{\text{g Cl}}}\right) = 0.732\text{ mol Cl}$$

We then divide the larger number of moles by the smaller number to obtain the Cl:Hg mole ratio:

$$\frac{\text{moles of Cl}}{\text{moles of Hg}} = \frac{0.732\text{ mol Cl}}{0.369\text{ mol Hg}} = \frac{1.98\text{ mol Cl}}{1\text{ mol Hg}}$$

Because of experimental errors, calculated values for a mole ratio may not be exact whole numbers, as in the calculation here. The number 1.98 is very close to 2, however, and so we can confidently conclude that the empirical formula for the compound is $HgCl_2$. The empirical formula is correct because its subscripts are the smallest integers that express the *ratio* of atoms present in the compound.

The general procedure for determining empirical formulas is outlined in **Figure 3.12**.



▲ **Figure 3.12 Procedure for calculating an empirical formula from percentage composition.**

Sample Exercise 3.10

Calculating an Empirical Formula

Ascorbic acid (vitamin C) contains 40.92% C, 4.58% H, and 54.50% O by mass. What is the empirical formula of ascorbic acid?

SOLUTION

Analyze We are to determine the empirical formula of a compound from the mass percentages of its elements.

Plan The strategy for determining the empirical formula involves the three steps given in Figure 3.12.

Solve

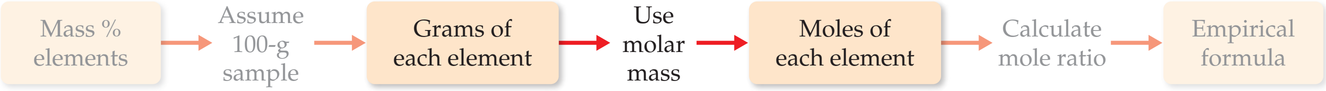
(**1**) For simplicity we assume we have exactly 100 g of material, although any other mass could also be used.

Mass % elements
Assume 100-g sample
Grams of each element
Use molar mass
Moles of each element
Calculate mole ratio
Empirical formula

In 100.00 g of ascorbic acid we have 40.92 g C, 4.58 g H, and 54.50 g O.

Continued

(**2**) Next, we calculate the number of moles of each element. We use atomic masses with four significant figures to match the precision of our experimental masses.

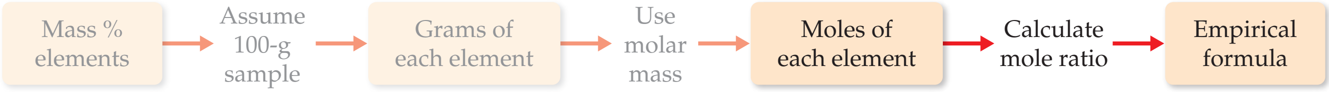


$$\text{Moles C} = (40.92\ \cancel{\text{g C}})\left(\frac{1\ \text{mol C}}{12.01\ \cancel{\text{g C}}}\right) = 3.407\ \text{mol C}$$

$$\text{Moles H} = (4.58\ \cancel{\text{g H}})\left(\frac{1\ \text{mol C}}{1.008\ \cancel{\text{g H}}}\right) = 4.54\ \text{mol H}$$

$$\text{Moles O} = (54.50\ \cancel{\text{g O}})\left(\frac{1\ \text{mol O}}{16.00\ \cancel{\text{g O}}}\right) = 3.406\ \text{mol O}$$

(**3**) We determine the simplest whole-number ratio of moles by dividing each number of moles by the smallest number of moles.



$$\text{C:}\frac{3.407}{3.406} = 1.000 \quad \text{H:}\frac{4.54}{3.406} = 1.33 \quad \text{O:}\frac{3.406}{3.406} = 1.000$$

The ratio for H is too far from 1 to attribute the difference to experimental error; in fact, it is quite close to $1\frac{1}{3}$. This suggests we should multiply the ratios by 3 to obtain whole numbers:

$$\text{C : H : O} = (3 \times 1 : 3 \times 1.33 : 3 \times 1) = (3 : 4 : 3)$$

Thus, the empirical formula is $C_3H_4O_3$.

Check It is reassuring that the subscripts are moderate-sized whole numbers. Also, calculating the percentage composition of $C_3H_4O_3$ gives values very close to the original percentages.

Practice Exercise

A 5.325-g sample of methyl benzoate, a compound used in the manufacture of perfumes, contains 3.758 g of carbon, 0.316 g of hydrogen, and 1.251 g of oxygen. What is the empirical formula of this substance?

Molecular Formulas from Empirical Formulas

For molecular substances, the empirical formula and the molecular formula are often different. For example, benzene has a molecular formula of C_6H_6, but its empirical formula CH is the same as that of the gas acetylene, whose molecular formula is C_2H_2. Knowledge of the empirical formula is insufficient to differentiate these two very different compounds. Fortunately, we can obtain the molecular formula for any compound from its empirical formula if we know the molecular weight of the compound, which can be measured by a variety of methods, including mass spectrometry. (Section 2.4) *The subscripts in the molecular formula of a substance are always whole-number multiples of the subscripts in its empirical formula*. (Section 2.6) This multiple can be found by dividing the molecular weight by the empirical formula weight:

$$\text{Whole-number multiple} = \frac{\text{molecular weight}}{\text{empirical formula weight}} \qquad [3.14]$$

In Sample Exercise 3.10, for example, the empirical formula of ascorbic acid was determined to be $C_3H_4O_3$. This means the empirical formula weight is $3(12.0\ \text{amu}) + 4(1.0\ \text{amu}) + 3(16.0\ \text{amu}) = 88.0\ \text{amu}$. The experimentally determined molecular weight is 176 amu. Thus, we find the whole-number multiple that converts the empirical formula to the molecular formula by dividing:

$$\text{Whole-number multiple} = \frac{\text{molecular weight}}{\text{empirical formula weight}} = \frac{176\ \text{amu}}{88.0\ \text{amu}} = 2$$

Consequently, we multiply the subscripts in the empirical formula by this multiple, giving the molecular formula: $C_6H_8O_6$.

Sample Exercise 3.11

Determining a Molecular Formula

Mesitylene, a hydrocarbon found in crude oil, has an empirical formula of C_3H_4 and an experimentally determined molecular weight of 121 amu. What is its molecular formula?

SOLUTION

Analyze We are given an empirical formula and a molecular weight of a compound and asked to determine its molecular formula.

Plan The subscripts in a compound's molecular formula are whole-number multiples of the subscripts in its empirical formula. We find the appropriate multiple by using Equation 3.14.

Solve The formula weight of the empirical formula C_3H_4 is

$$3(12.0\text{ amu}) + 4(1.0\text{ amu}) = 40.0\text{ amu}$$

Next, we use this value in Equation 3.14:

$$\text{Whole-number multiple} = \frac{\text{molecular weight}}{\text{empirical formula weight}} = \frac{121}{40.0} = 3.03$$

Only whole-number ratios make physical sense because molecules contain whole atoms. The 3.03 in this case could result from a small experimental error in the molecular weight. We therefore multiply each subscript in the empirical formula by 3 to give the molecular formula: C_9H_{12}.

Check We can have confidence in the result because dividing molecular weight by empirical formula weight yields nearly a whole number.

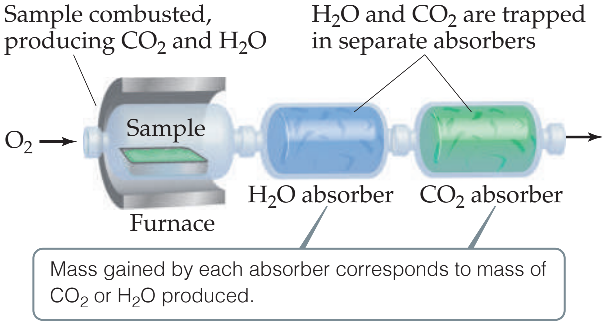
Practice Exercise

Ethylene glycol, used in automobile antifreeze, is 38.7% C, 9.7% H, and 51.6% O by mass. Its molar mass is 62.1 g/mol. (**a**) What is the empirical formula of ethylene glycol? (**b**) What is its molecular formula?

Combustion Analysis

One technique for determining empirical formulas in the laboratory is *combustion analysis*, commonly used for compounds containing principally carbon and hydrogen.

When a compound containing carbon and hydrogen is completely combusted in an apparatus such as that shown in **Figure 3.13**, the carbon is converted to CO_2 and the hydrogen is converted to H_2O. (Section 3.2) From the masses of CO_2 and H_2O we can calculate the number of moles of C and H in the original sample and thereby the empirical formula. If a third element is present in the compound, its mass can be determined by subtracting the measured masses of C and H from the original sample mass.



Sample combusted, producing CO_2 and H_2O
H_2O and CO_2 are trapped in separate absorbers

◀ **Figure 3.13 Apparatus for combustion analysis.**

Sample Exercise 3.12

Determining an Empirical Formula by Combustion Analysis

Isopropyl alcohol, sold as rubbing alcohol, is composed of C, H, and O. Combustion of 0.255 g of isopropyl alcohol produces 0.561 g of CO_2 and 0.306 g of H_2O. Determine the empirical formula of isopropyl alcohol.

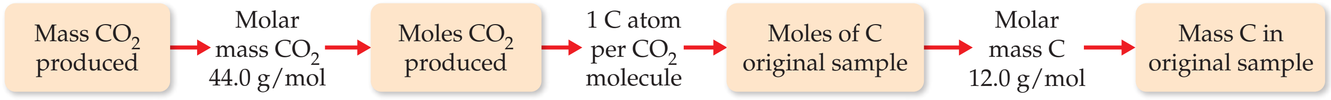
SOLUTION

Analyze We are told that isopropyl alcohol contains C, H, and O atoms, and we are given the quantities of CO_2 and H_2O produced when a given quantity of the alcohol is combusted. We must determine the empirical formula for isopropyl alcohol, a task that requires us to calculate the number of moles of C, H, and O in the sample.

Plan We can use the mole concept to calculate grams of C in the CO_2 and grams of H in the H_2O—the masses of C and H in the alcohol before combustion. The mass of O in the compound equals the mass of the original sample minus the sum of the C and H masses. Once we have the C, H, and O masses, we can proceed as in Sample Exercise 3.10.

Continued

Solve Because all of the carbon in the sample is converted to CO_2, we can use dimensional analysis and the following steps to calculate the mass C in the sample.



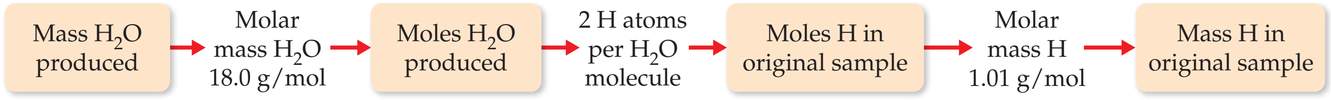
Mass CO_2 produced
Molar mass CO_2 44.0 g/mol
Moles CO_2 produced
1 C atom per CO_2 molecule
Moles of C original sample
Molar mass C 12.0 g/mol
Mass C in original sample

Using the values given in this example, we see that the mass of C is

$$\text{Grams C} = (0.561\ \text{g}\ \cancel{\text{CO}_2})\left(\frac{1\ \cancel{\text{mol CO}_2}}{44.0\ \cancel{\text{g CO}_2}}\right)\left(\frac{1\ \cancel{\text{mol C}}}{1\ \cancel{\text{mol CO}_2}}\right)\left(\frac{12.0\ \text{g C}}{1\ \cancel{\text{mol C}}}\right)$$

$$= 0.153\ \text{g C}$$

Because all of the hydrogen in the sample is converted to H_2O, we can use dimensional analysis and the following steps to calculate the mass H in the sample. We use three significant figures for the atomic mass of H to match the significant figures in the mass of H_2O produced.



Mass H_2O produced
Molar mass H_2O 18.0 g/mol
Moles H_2O produced
2 H atoms per H_2O molecule
Moles H in original sample
Molar mass H 1.01 g/mol
Mass H in original sample

Using the values given in this example, we find that the mass of H is

$$\text{Grams H} = (0.306\ \text{g}\ \cancel{\text{H}_2\text{O}})\left(\frac{1\ \cancel{\text{mol H}_2\text{O}}}{18.0\ \cancel{\text{g H}_2\text{O}}}\right)\left(\frac{2\ \cancel{\text{mol H}}}{1\ \cancel{\text{mol H}_2\text{O}}}\right)\left(\frac{1.01\ \text{g H}}{1\ \cancel{\text{mol H}}}\right) = 0.0343\ \text{g H}$$

The mass of the sample, 0.255 g, is the sum of the masses of C, H, and O. Thus, the O mass is

$$\text{Mass of O} = \text{mass of sample} - (\text{mass of C} + \text{mass of H}) = 0.255\ \text{g} - (0.153\ \text{g} + 0.0343\ \text{g}) = 0.068\ \text{g O}$$

The number of moles of C, H, and O in the sample is therefore

$$\text{Moles C} = (0.153\ \text{g}\ \cancel{\text{C}})\left(\frac{1\ \text{mol C}}{12.0\ \text{g}\ \cancel{\text{C}}}\right) = 0.0128\ \text{mol C}$$

$$\text{Moles H} = (0.0343\ \text{g}\ \cancel{\text{H}})\left(\frac{1\ \text{mol H}}{1.01\ \text{g}\ \cancel{\text{H}}}\right) = 0.0340\ \text{mol H}$$

$$\text{Moles O} = (0.068\ \text{g}\ \cancel{\text{O}})\left(\frac{1\ \text{mol O}}{16.0\ \text{g}\ \cancel{\text{O}}}\right) = 0.0043\ \text{mol O}$$

To find the empirical formula, we must compare the relative number of moles of each element in the sample, as illustrated in Sample Exercise 3.11.

$$\text{C}: \frac{0.0128}{0.0043} = 3.0 \quad \text{H}: \frac{0.0340}{0.0043} = 7.9 \quad \text{O}: \frac{0.0043}{0.0043} = 1.0$$

The first two numbers are close to the whole numbers 3 and 8, giving the empirical formula C_3H_8O.

(**a**) Caproic acid, responsible for the odor of dirty socks, is composed of C, H, and O atoms. Combustion of a 0.225-g sample of this compound produces 0.512 g CO_2 and 0.209 g H_2O. What is the empirical formula of caproic acid?

(**b**) Caproic acid has a molar mass of 116 g/mol. What is its molecular formula?

Self-Assessment Exercises

SAE 3.13 In 2001, Japanese researchers found that a binary compound containing magnesium and boron conducts electricity with no resistance when cooled below 39 K. Elemental analysis showed that the compound is 52.9% magnesium and 47.1% boron by mass. What is the empirical formula of this compound? (**a**) MgB (**b**) Mg_2B (**c**) MgB_2 (**d**) Mg_2B_4

SAE 3.14 Styrene is the monomer used to make the polymer polystyrene. Elemental analysis shows that styrene is 92.3% carbon and 7.7% hydrogen by mass. Various techniques can be used to show that its molar mass is 104.2 g/mol. What is the molecular formula of styrene? (**a**) CH (**b**) C_8H_5 (**c**) C_8H_8 (**d**) C_7H_{20}

SAE 3.15 Isopentyl acetate is the molecule largely responsible for the aroma and taste of bananas. It is made up of carbon, hydrogen, and oxygen. Combustion of a 3.256-g sample of isopentyl acetate produces 7.706 g CO_2 and 3.156 g H_2O. Using these results, what is the correct empirical formula for isopentyl acetate? (**a**) C_3H_3O (**b**) CH_2 (**c**) $C_{3.5}H_7O$ (**d**) $C_7H_{14}O_2$

3.6 Quantitative Information from Balanced Equations

Learning Objective

When you finish Section 3.6, you should be able to:

- Determine the quantities (grams, moles, or molecules) of products formed and/or reactants consumed in a chemical reaction where the quantity of one reactant that is identified limits the extent of the reaction.

When a chemical reaction is carried out, it's vital to understand how much of each product will be produced and how much of each reactant will be consumed. Carrying out chemical reactions without this knowledge can lead to unintended consequences. Maybe an expensive reactant will be wasted because much more of it was added than needed. A reaction might generate more gas than the reaction container can hold, leading to an explosion. In some reactions, particularly those involving solids, it can be difficult to separate the desired product from excess reactants. In this section, we show how to calculate the quantities of reactants consumed and products produced, given a balanced chemical equation representing the reaction.

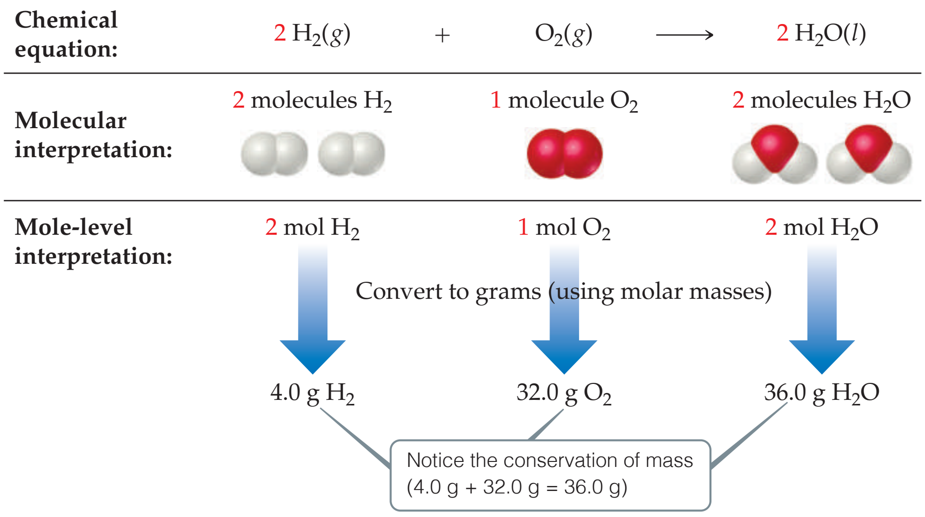
The coefficients in a chemical equation represent the relative numbers of molecules in a reaction. The mole concept allows us to convert this information to the masses of the substances in the reaction. For instance, the coefficients in the balanced equation

$$2H_2(g) + O_2(g) \longrightarrow 2H_2O(l) \qquad [3.15]$$

indicate that two molecules of H_2 react with one molecule of O_2 to form two molecules of H_2O. It follows that the relative numbers of moles are identical to the relative numbers of molecules:

$$\begin{array}{ccccc}
2\,H_2(g) & + & O_2(g) & \longrightarrow & 2\,H_2O(l) \\
2\text{ molecules} & & 1\text{ molecule} & & 2\text{ molecules} \\
2(6.02\times10^{23}\text{ molecules}) & & 1(6.02\times10^{23}\text{ molecules}) & & 2(6.02\times10^{23}\text{ molecules}) \\
2\text{ mol} & & 1\text{ mol} & & 2\text{ mol}
\end{array}$$

We can generalize this observation to all balanced chemical equations: *The coefficients in a balanced chemical equation indicate both the relative numbers of molecules (or formula units) in the reaction and the relative numbers of moles*. **Figure 3.14** shows how this result corresponds to the law of conservation of mass.



Chemical equation:
$2\,H_2(g) + O_2(g) \longrightarrow 2\,H_2O(l)$
Molecular interpretation:
2 molecules H_2
1 molecule O_2
2 molecules H_2O
Mole-level interpretation:
2 mol H_2
1 mol O_2
2 mol H_2O
Convert to grams (using molar masses)
4.0 g H_2
32.0 g O_2
36.0 g H_2O
Notice the conservation of mass
(4.0 g + 32.0 g = 36.0 g)

Figure 3.14 Interpreting a balanced chemical equation quantitatively.

The quantities 2 mol H_2, 1 mol O_2, and 2 mol H_2O given by the coefficients in Equation 3.15 are called *stoichiometrically equivalent quantities*. The relationship between these quantities can be represented as

$$2\text{ mol } H_2 \hat{=} 1\text{ mol } O_2 \hat{=} 2\text{ mol } H_2O$$

where the $\hat{=}$ symbol means "is stoichiometrically equivalent to." Stoichiometric relations such as these can be used to convert between quantities of reactants and products in a chemical reaction. For example, the number of moles of H_2O produced from 1.57 mol of O_2 is

$$\text{Moles } H_2O = (1.57\ \cancel{\text{mol } O_2})\left(\frac{2\ \text{mol } H_2O}{1\ \cancel{\text{mol } O_2}}\right) = 3.14\ \text{mol } H_2O$$

As an additional example, consider the combustion of butane C_4H_{10}, the fuel in disposable lighters:

$$2\,C_4H_{10}(l) + 13\,O_2(g) \longrightarrow 8\,CO_2(g) + 10\,H_2O(g) \qquad [3.16]$$

Let's calculate the mass of CO_2 produced when 1.00 g of C_4H_{10} is burned. The coefficients in Equation 3.13 tell us how the amount of C_4H_{10} consumed is related to the amount of CO_2 produced: $2\ \text{mol } C_4H_{10} \simeq 8\ \text{mol } CO_2$. To use this stoichiometric relationship, we must convert grams of C_4H_{10} to moles using the molar mass of C_4H_{10}, 58.0 g/mol:

$$\begin{aligned}\text{Moles } C_4H_{10} &= (1.00\ \cancel{\text{g } C_4H_{10}})\left(\frac{1\ \text{mol } C_4H_{10}}{58.0\ \cancel{\text{g } C_4H_{10}}}\right)\\ &= 1.72 \times 10^{-2}\ \text{mol } C_4H_{10}\end{aligned}$$

We then use the stoichiometric factor from the balanced equation to calculate moles of CO_2:

$$\begin{aligned}\text{Moles } CO_2 &= (1.72 \times 10^{-2}\ \cancel{\text{mol } C_4H_{10}})\left(\frac{8\ \text{mol } CO_2}{2\ \cancel{\text{mol } C_4H_{10}}}\right)\\ &= 6.88 \times 10^{-2}\ \text{mol } CO_2\end{aligned}$$

Finally, we use the molar mass of CO_2, 44.0 g/mol, to calculate the mass of CO_2 in grams:

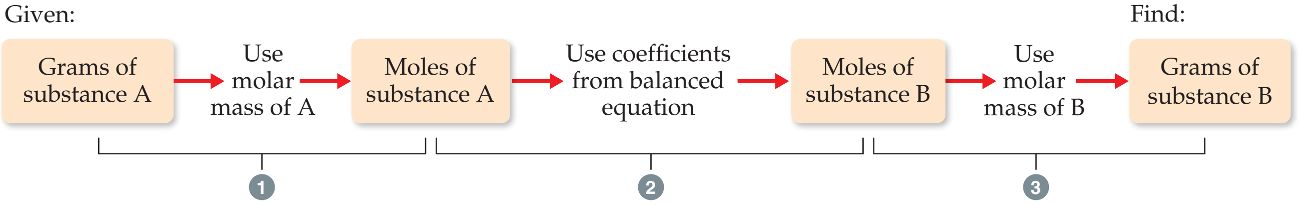
$$\begin{aligned}\text{Grams } CO_2 &= (6.88 \times 10^{-2}\ \cancel{\text{mol } CO_2})\left(\frac{44.0\ \text{g } CO_2}{1\ \cancel{\text{mol } CO_2}}\right)\\ &= 3.03\ \text{g } CO_2\end{aligned}$$

This conversion sequence involves three steps, as illustrated in **Figure 3.15**. These three conversions can be combined in a single equation:

$$\begin{aligned}\text{Grams } CO_2 &= (1.00\ \cancel{\text{g } C_4H_{10}})\left(\frac{1\ \cancel{\text{mol } C_4H_{10}}}{58.0\ \cancel{\text{g } C_4H_{10}}}\right)\left(\frac{8\ \cancel{\text{mol } CO_2}}{2\ \cancel{\text{mol } C_4H_{10}}}\right)\left(\frac{44.0\ \text{g } CO_2}{1\ \cancel{\text{mol } CO_2}}\right)\\ &= 3.03\ \text{g } CO_2\end{aligned}$$

To calculate the amount of O_2 consumed in the reaction of Equation 3.16, we again rely on the coefficients in the balanced equation for our stoichiometric factor, $2\ \text{mol } C_4H_{10} \simeq 13\ \text{mol } O_2$:

$$\begin{aligned}\text{Grams } O_2 &= (1.00\ \cancel{\text{g } C_4H_{10}})\left(\frac{1\ \cancel{\text{mol } C_4H_{10}}}{58.0\ \cancel{\text{g } C_4H_{10}}}\right)\left(\frac{13\ \cancel{\text{mol } O_2}}{2\ \cancel{\text{mol } C_4H_{10}}}\right)\left(\frac{32.0\ \text{g } O_2}{1\ \cancel{\text{mol } O_2}}\right)\\ &= 3.59\ \text{g } O_2\end{aligned}$$



▲ **Figure 3.15 Procedure for calculating amounts of reactants consumed or products formed in a reaction.** The number of grams of a reactant consumed or product formed can be calculated in three steps, starting with the number of grams of any reactant or product.

Many chemical reactions either consume or produce heat (Figure 3.7). This heat is also a stoichiometric quantity. For instance, if a given reaction with a given number of reactant moles produces 100 J of energy in the form of heat, performing the reaction with twice the number of moles of reactants will produce 200 J of heat. We explore this concept further in Chapter 5.

Sample Exercise 3.13

Calculating Amounts of Reactants and Products

Determine how many grams of water are produced in the oxidation of 1.00 g of glucose, $C_6H_{12}O_6$:

$$C_6H_{12}O_6(s) + 6\,O_2(g) \longrightarrow 6\,CO_2(g) + 6\,H_2O(l)$$

SOLUTION

Analyze We are given the mass of a reactant and must determine the mass of a product in the given reaction.

Plan We follow the general strategy outlined in Figure 3.15:

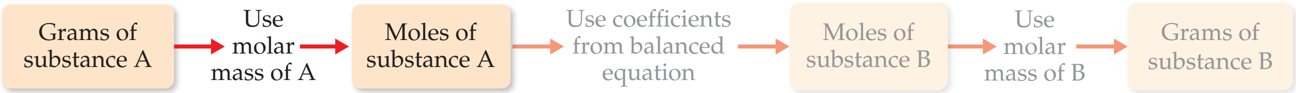
(**1**) Convert grams of $C_6H_{12}O_6$ to moles using the molar mass of $C_6H_{12}O_6$.

(**2**) Convert moles of $C_6H_{12}O_6$ to moles of H_2O using the stoichiometric relationship 1 mol $C_6H_{12}O_6 \simeq$ 6 mol H_2O.

(**3**) Convert moles of H_2O to grams using the molar mass of H_2O.

Solve

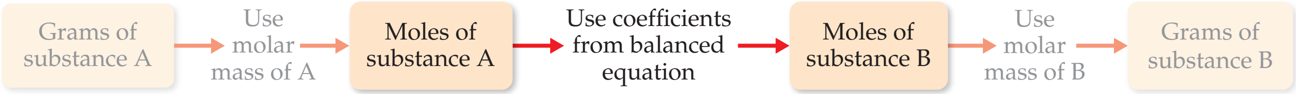
(**1**) First we convert grams of $C_6H_{12}O_6$ to moles using the molar mass of $C_6H_{12}O_6$.



Grams of substance A
Use molar mass of A
Moles of substance A
Use coefficients from balanced equation
Moles of substance B
Use molar mass of B
Grams of substance B

$$\text{Moles } C_6H_{12}O_6 = (1.00\,\cancel{g\,C_6H_{12}O_6})\left(\frac{1\text{ mol }C_6H_{12}O_6}{180.0\,\cancel{g\,C_6H_{12}O_6}}\right)$$

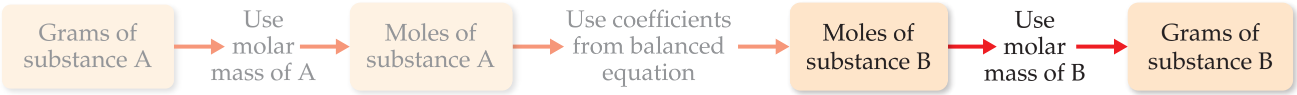
(**2**) Next, we convert moles of $C_6H_{12}O_6$ to moles of H_2O using the stoichiometric relationship 1 mol $C_6H_{12}O_6 \simeq$ 6 mol H_2O.



Grams of substance A
Use molar mass of A
Moles of substance A
Use coefficients from balanced equation
Moles of substance B
Use molar mass of B
Grams of substance B

$$\text{Moles } H_2O = (1.00\,g\,C_6H_{12}O_6)\left(\frac{1\,\cancel{\text{mol }C_6H_{12}O_6}}{180.0\,\cancel{g\,C_6H_{12}O_6}}\right)\left(\frac{6\text{ mol }H_2O}{1\,\cancel{\text{mol }C_6H_{12}O_6}}\right)$$

(**3**) Finally, we convert moles of H_2O to grams using the molar mass of H_2O.



Grams of substance A
Use molar mass of A
Moles of substance A
Use coefficients from balanced equation
Moles of substance B
Use molar mass of B
Grams of substance B

$$\begin{aligned}\text{Grams } H_2O &= (1.00\,\cancel{g\,C_6H_{12}O_6})\left(\frac{1\,\cancel{\text{mol }C_6H_{12}O_6}}{180.0\,\cancel{g\,C_6H_{12}O_6}}\right)\left(\frac{6\,\cancel{\text{mol }H_2O}}{1\,\cancel{\text{mol }C_6H_{12}O_6}}\right)\left(\frac{18.0\,g\,H_2O}{1\,\cancel{\text{mol }H_2O}}\right)\\ &= 0.600\,g\,H_2O\end{aligned}$$

Check We can check the reasonableness of our result by doing a ballpark estimate of the mass of H_2O. Because the molar mass of glucose is 180 g/mol, 1 g of glucose equals 1/180 mol. Because 1 mol of glucose yields 6 mol H_2O, we would have $6/180 = 1/30$ mol H_2O. The molar mass of water is 18 g/mol, so we have $1/30 \times 18 = 6/10 = 0.6$ g of H_2O, which agrees with the full calculation. The units, grams H_2O, are correct. The initial data had three significant figures, so three significant figures for the answer is correct.

Practice Exercise

Decomposition of $KClO_3$ is sometimes used to prepare small amounts of O_2 in the laboratory: $2\,KClO_3(s) \longrightarrow 2\,KCl(s) + 3\,O_2(g)$. How many grams of O_2 can be prepared from 4.50 g of $KClO_3$?

Self-Assessment Exercises

SAE 3.16 When 5.00 g of methane, CH_4, reacts with an excess of oxygen in a combustion reaction, what quantity of H_2O is produced? (**a**) 2.81 g (**b**) 5.60 g (**c**) 10.0 g (**d**) 11.2 g

SAE 3.17 When heated sufficiently, lead(IV) oxide undergoes the following decomposition reaction: $2\,PbO_2(s) \longrightarrow 2\,PbO(s) + O_2(g)$. When a PbO_2 sample is heated, it produces 0.250 g of O_2. What is the mass of PbO_2 present prior to heating? (**a**) 0.0156 g (**b**) 0.500 g (**c**) 3.49 g (**d**) 3.74 g

3.7 | Limiting Reactants

Learning Objectives

When you finish Section 3.7, you should be able to:

- Determine the limiting reactant for a reaction from the quantities (grams, moles, or molecules) of each reactant present before the reaction starts.
- Calculate the theoretical yield for a reaction from the quantities (grams, moles, or molecules) of the limiting reactant present before the reaction starts.
- Calculate the percent yield of a chemical reaction from the actual yield and the theoretical yield of a given product.

Often the reactants used in a chemical reaction are not present in precise stoichiometric amounts. For example, a natural gas-fired power plant generates electricity by producing hot gases that drive turbines, predominantly through the following combustion reaction:

$$CH_4(g) + 2\,O_2(g) \longrightarrow CO_2(g) + 2\,H_2O(g) \qquad [3.17]$$

Power plants typically operate with an excess of $O_2(g)$ to extract the maximum energy from the hydrocarbon fuel and minimize production of harmful by-products, like carbon monoxide, that result from incomplete combustion. Consequently, the amount of CH_4 introduced determines how much CO_2 and H_2O are produced. In this section, we show how to do quantitative calculations for reactions where the reactants are not present in stoichiometrically equivalent quantities.

Suppose you wish to make several sandwiches using one slice of cheese and two slices of bread for each. Using Bd = bread, Ch = cheese, and Bd_2Ch = sandwich, we can represent the recipe for making a sandwich as a chemical equation:

$$2\,Bd + Ch \longrightarrow Bd_2Ch$$

If you have ten slices of bread and seven slices of cheese, you can make only five sandwiches and will have two slices of cheese left over. In this example, the amount of bread limits the number of sandwiches.

An analogous situation occurs in chemical reactions when one reactant is used up before the others. The reaction stops as soon as any reactant is totally consumed, leaving the excess reactants as leftovers. Suppose, for example, we have a mixture of 10 mol H_2 and 7 mol O_2, which react to form water:

$$2\,H_2(g) + O_2(g) \longrightarrow 2\,H_2O(g)$$

Because $2\,\text{mol}\,H_2 \bumpeq 1\,\text{mol}\,O_2$, the number of moles of O_2 needed to react with all the H_2 is

$$\text{Moles } O_2 = (10\,\cancel{\text{mol}\,H_2})\left(\frac{1\text{ mol }O_2}{2\,\cancel{\text{mol}\,H_2}}\right) = 5\text{ mol }O_2$$

Because 7 mol O_2 is available at the start of the reaction, $7\,\text{mol}\,O_2 - 5\,\text{mol}\,O_2 = 2\,\text{mol}\,O_2$ is still present when the H_2 is fully consumed.

The reactant that is completely consumed in a reaction is called the **limiting reactant** because it determines, or limits, the amount of product formed. The other reactants are sometimes called *excess reactants*. In our example, shown in **Figure 3.16**, H_2 is the limiting reactant, which means that once all the H_2 has been consumed, the reaction stops. At that point some of the excess reactant O_2 is left over.

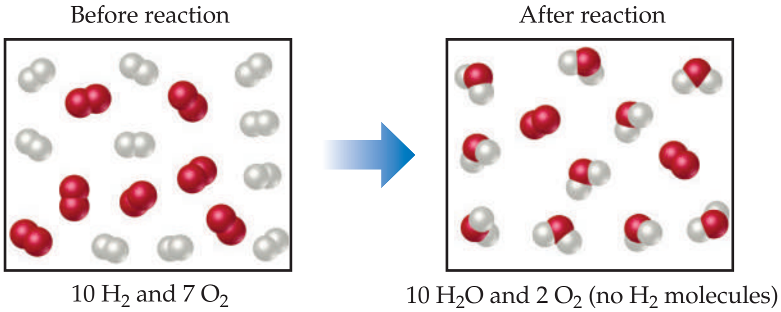
There are no restrictions on the starting amounts of reactants in any reaction. Indeed, many reactions are carried out using an excess of one or more reactants. The quantities of reactants consumed and products formed, however, are restricted by the quantity of the limiting reactant. For example, when a combustion reaction takes place in the open air, oxygen is plentiful and is therefore the excess reactant. If you run out of gasoline while driving, the car stops because the gasoline is the limiting reactant in the combustion reaction that moves the car.

Before we leave the example illustrated in Figure 3.16, let's summarize the data:

	$2\,H_2(g)$	+	$O_2(g)$	$\longrightarrow$	$2\,H_2O(g)$
Before reaction:	10 mol		7 mol		0 mol
Change (reaction):	−10 mol		−5 mol		+10 mol
After reaction:	0 mol		2 mol		10 mol

The second line in the table (Change) summarizes the amounts of reactants consumed (where this consumption is indicated by the minus signs) and the amount of the product formed (indicated by the plus sign). These quantities are restricted by the quantity of the limiting reactant and depend on the coefficients in the balanced equation. The mole ratio $H_2{:}O_2{:}H_2O$ = 10:5:10 is a multiple of the ratio of the coefficients in the balanced equation, 2:1:2. The after-reaction quantities depend on the before-reaction

Go Figure If the amount of H_2 is doubled, how many moles of H_2O will form?



▲ **Figure 3.16 Limiting reactant.** Because H_2 is completely consumed, it is the limiting reactant. Because some O_2 is left over after the reaction is complete, it is the excess reactant. The amount of H_2O formed depends on the amount of limiting reactant, H_2.

quantities and their changes. The after-reaction quantities are found by adding the before quantity and change quantity for each column. The amount of the limiting reactant (H_2) must be zero at the end of the reaction. What remains is 2 mol O_2 (excess reactant) and 10 mol H_2O (product).

Sample Exercise 3.14

Calculating the Amount of Product Formed from a Limiting Reactant

The most important commercial process for converting N_2 from the air into nitrogen-containing compounds is based on the reaction of N_2 and H_2 to form ammonia (NH_3):

$$N_2(g) + 3H_2(g) \longrightarrow 2NH_3(g)$$

How many moles of NH_3 can be formed from 3.0 mol of N_2 and 6.0 mol of H_2?

SOLUTION

Analyze We are asked to calculate the number of moles of product, NH_3, given the quantities of each reactant, N_2 and H_2, available in a reaction. This is a limiting reactant problem.

Plan If we assume one reactant is completely consumed, we can calculate how much of the second reactant is needed. By comparing the calculated quantity of the second reactant with the amount available, we can determine which reactant is limiting. We then proceed with the calculation, using the quantity of the limiting reactant.

Solve The number of moles of H_2 needed for complete consumption of 3.0 mol of N_2 is

$$\text{Moles } H_2 = (3.0\ \cancel{\text{mol } N_2})\left(\frac{3\text{ mol } H_2}{1\ \cancel{\text{mol } N_2}}\right) = 9.0\text{ mol } H_2$$

Because only 6.0 mol H_2 is available, we will run out of H_2 before the N_2 is gone, which tells us that H_2 is the limiting reactant. Therefore, we use the quantity of H_2 to calculate the quantity of NH_3 produced:

$$\text{Moles } NH_3 = (6.0\ \cancel{\text{mol } H_2})\left(\frac{2\text{ mol } NH_3}{3\ \cancel{\text{mol } H_2}}\right) = 4.0\text{ mol } NH_3$$

Notice that we can calculate not only the number of moles of NH_3 formed but also the number of moles of each reactant remaining after the reaction. Notice also that although the initial number of moles of H_2 is greater than the initial number of moles of N_2, H_2 is nevertheless the limiting reactant because of its larger coefficient in the balanced equation.

Check Examine the change row of the summary table to see that the mole ratio of reactants consumed and product formed, 2:6:4, is a multiple of the coefficients in the balanced equation, 1:3:2. We confirm that H_2 is the limiting reactant because it is completely consumed in the reaction, leaving 0 mol at the end. Because 6.0 mol H_2 has two significant figures, our answer has two significant figures.

Comment It is useful to summarize the reaction data in a table:

	$N_2(g)$ +	$3H_2(g) \longrightarrow$	$2NH_3(g)$
Before reaction:	3.0 mol	6.0 mol	0 mol
Change (reaction):	−2.0 mol	−6.0 mol	+4.0 mol
After reaction:	1.0 mol	0 mol	4.0 mol

▶ **Practice Exercise**

(**a**) When 1.50 mol of Al and 3.00 mol of Cl_2 combine in the reaction $2Al(s) + 3Cl_2(g) \longrightarrow 2AlCl_3(s)$, which is the limiting reactant? (**b**) How many moles of $AlCl_3$ are formed? (**c**) How many moles of the excess reactant remain at the end of the reaction?

Theoretical and Percent Yields

The quantity of product calculated to form when the limiting reactant is fully consumed is called the **theoretical yield**. The amount of product actually obtained, called the *actual yield*, is almost always less than (and can never be greater than) the theoretical yield. There are many reasons for this difference. Some of the reactants may not react, for example, or they may react in a way different from that desired, leading to side reactions. In addition, it is not always possible to recover all of the product from the reaction mixture. The **percent yield** is the actual yield divided by the theoretical yield, multiplied by 100% to convert to percent:

$$\text{Percent yield} = \frac{\text{actual yield}}{\text{theoretical yield}} \times 100\% \qquad [3.18]$$

Sample Exercise 3.15

Calculating Theoretical Yield and Percent Yield

Adipic acid, $H_2C_6H_8O_4$, used to produce nylon, is made commercially by a reaction between cyclohexane (C_6H_{12}) and oxygen (O_2):

$$2\,C_6H_{12}(l) + 5\,O_2(g) \longrightarrow 2\,H_2C_6H_8O_4(l) + 2\,H_2O(g)$$

(**a**) Assume that you carry out this reaction with 25.0 g of cyclohexane and that cyclohexane is the limiting reactant. What is the theoretical yield of adipic acid? (**b**) If you obtain 33.5 g of adipic acid, what is the percent yield for the reaction?

SOLUTION

Analyze We are given a chemical equation and the quantity of the limiting reactant (25.0 g of C_6H_{12}). We are asked to calculate the theoretical yield of a product $H_2C_6H_8O_4$ and the percent yield if only 33.5 g of product is obtained.

Plan

(**a**) The theoretical yield, which is the calculated quantity of adipic acid formed, can be calculated using the sequence of conversions shown in Figure 3.15.

(**b**) The percent yield is calculated by using Equation 3.18 to compare the given actual yield (33.5 g) with the theoretical yield.

Solve

(**a**) The theoretical yield is:

$$\text{Grams } H_2C_6H_8O_4 = (25.0\ \cancel{\text{g } C_6H_{12}})\left(\frac{1\ \cancel{\text{mol } C_6H_{12}}}{84.0\ \cancel{\text{g } C_6H_{12}}}\right)\left(\frac{2\ \cancel{\text{mol } H_2C_6H_8O_4}}{2\ \cancel{\text{mol } C_6H_{12}}}\right)\left(\frac{146.0\text{ g } H_2C_6H_8O_4}{1\ \cancel{\text{mol } H_2C_6H_8O_4}}\right) = 43.5\text{ g } H_2C_6H_8O_4$$

(**b**) The percent yield is:

$$\text{Percent yield} = \frac{\text{actual yield}}{\text{theoretical yield}} \times 100\% = \frac{33.5\text{ g}}{43.5\text{ g}} \times 100\% = 77.0\%$$

Check We can check our answer in (**a**) by doing a ballpark calculation. From the balanced equation we know that each mole of cyclohexane gives 1 mol adipic acid. We have $25/84 \approx 25/75 = 0.33$ mol hexane, so we expect 0.33 mol adipic acid, which equals about $0.33 \times 150 = 50$ g, roughly the same magnitude as the 43.5 g obtained in the more detailed calculation. In addition, our answer has the appropriate units and number of significant figures. In (**b**) the answer is less than 100%, as it must be from the definition of percent yield.

▶ Practice Exercise

Imagine you are working on ways to improve the process by which iron ore containing Fe_2O_3 is converted into iron:

$$Fe_2O_3(s) + 3\,CO(g) \longrightarrow 2\,Fe(s) + 3\,CO_2(g)$$

(**a**) If you start with 150 g of Fe_2O_3 as the limiting reactant, what is the theoretical yield of Fe? (**b**) If your actual yield is 87.9 g, what is the percent yield?

Self-Assessment Exercises

SAE 3.18 If eight molecules of CO and five molecules of O_2 react to form CO_2, what is the limiting reactant, and how many molecules of the excess reactant will remain when the reaction is complete?

(**a**) Limiting reactant = O_2, three molecules of CO remaining
(**b**) Limiting reactant = O_2, one molecule of CO remaining
(**c**) Limiting reactant = CO, one molecule of O_2 remaining
(**d**) Limiting reactant = CO, four molecules of O_2 remaining

SAE 3.19 If 1.75 g of titanium metal reacts with 1.25 g of oxygen gas to form titanium(IV) oxide, what is the theoretical yield of the product? (**a**) 1.25 g (**b**) 1.56 g (**c**) 2.92 g (**d**) 3.12 g

SAE 3.20 Ammonia reacts with hydrogen chloride in the gas phase to produce the ionic compound ammonium chloride via the reaction $NH_3(g) + HCl(g) \longrightarrow NH_4Cl(s)$. What is the percent yield of ammonium chloride if 0.81 g of NH_4Cl is formed when 0.75 g of NH_3 is reacted with 0.62 g HCl? (**a**) 34% (**b**) 59% (**c**) 89% (**d**) 91%

STRATEGIES FOR SUCCESS Design an Experiment

One of the most important skills you can learn in school is how to think like a scientist. Questions such as: "What experiment might test this hypothesis?", "How do I interpret these data?", and "Do these data support the hypothesis?" are asked every day by chemists and other scientists as they go about their work.

We want you to become a good critical thinker as well as an active, logical, and curious learner. For this purpose, starting in this chapter, we include at the end of each chapter a special exercise called "Design an Experiment." Here is an example:

Is milk a pure liquid or a mixture of chemical components in water? Design an experiment to distinguish between these two possibilities.

You might already know the answer—milk is indeed a mixture of components in water—but the goal is to think of how to demonstrate this in practice. Upon thinking about it, you will likely realize that the key idea for this experiment is separation: You can prove that milk is a mixture of chemical components if you can figure out how to separate these components.

Testing a hypothesis is a creative endeavor. While some experiments may be more efficient than others, there is often more than one good way to test a hypothesis. Our question about milk, for example, might be explored by an experiment in which you boil a known quantity of milk until it is dry. Does a solid residue form in the bottom of the pan? If so, you could weigh it and calculate the percentage of solids in milk, which would offer good evidence that milk is a mixture. If there is no residue after boiling, then you still cannot distinguish between the two possibilities.

What other experiments might you do to demonstrate that milk is a mixture? You could put a sample of milk in a centrifuge, which you might have used in a biology lab, spin your sample, and observe if any solids collect at the bottom of the centrifuge tube; large molecules can be separated in this way from a mixture. Keep an open mind: Lacking a centrifuge, how else might you separate solids in the milk? You could consider using a filter with really tiny holes in it or perhaps even a fine strainer. You could propose that if milk were poured through this filter, some (large) solid components should stay on the top of the filter, while water (and really small molecules or ions) would pass through the filter. That result would be evidence that milk is a mixture. Does such a filter exist? Yes! But for our purposes, the existence of such a filter is not the point. The point is, can you use your imagination and your knowledge of chemistry to design a reasonable experiment? Don't worry too much about the exact apparatus you need for the Design an Experiment exercises. The goal is to imagine what you would need to do, or what kind of data you would need to collect, in order to answer the question. If your instructor allows it, you can collaborate with others in your class to develop ideas. Scientists discuss their ideas with other scientists all the time. We find that discussing ideas, and refining them, makes us better scientists and helps us collectively answer important questions.

The design and interpretation of scientific experiments is at the heart of the scientific method. Think of the Design an Experiment exercises as puzzles that can be solved in various ways, and enjoy your explorations!

Chapter Summary and Key Terms

CHEMICAL EQUATIONS (INTRODUCTION AND SECTION 3.1) The study of the quantitative relationships between chemical formulas and chemical equations is known as **stoichiometry**. One of the important concepts of stoichiometry is the **law of conservation of mass**, which states that the total mass of the products of a chemical reaction is the same as the total mass of the reactants. The same numbers of atoms of each type are present before and after a chemical reaction. A balanced **chemical equation** shows equal numbers of atoms of each element on each side of the equation. Equations are balanced by placing coefficients in front of the chemical formulas for the **reactants** and **products** of a reaction, not by changing the subscripts in chemical formulas.

SIMPLE PATTERNS OF CHEMICAL REACTIVITY (SECTION 3.2) Among the reaction types described in this chapter are (1) **combination reactions**, in which two reactants combine to form one product; (2) **decomposition reactions**, in which a single reactant forms two or more products; and (3) **combustion reactions** in oxygen, in which a substance, typically a hydrocarbon, reacts rapidly with O_2 to form CO_2 and H_2O.

FORMULA WEIGHTS (SECTION 3.3) Much quantitative information can be determined from chemical formulas and balanced chemical equations by using atomic weights. The **formula weight** of a compound equals the sum of the atomic weights of the atoms in its formula. If the formula is a molecular formula, the formula weight is also called the **molecular weight**. Atomic weights and formula weights can be used to determine the **elemental composition** of a compound.

AVOGADRO'S NUMBER AND THE MOLE (SECTION 3.4) A mole of any substance contains **Avogadro's number** (6.02×10^{23}) of formula units of that substance. The mass of a **mole** of atoms, molecules, or ions (the **molar mass**) equals the formula weight of that material expressed in grams. The mass of 1 molecule of H_2O, for example, is 18.0 amu, so the mass of 1 mol of H_2O is 18.0 g. That is, the molar mass of H_2O is 18.0 g/mol.

EMPIRICAL FORMULAS FROM ANALYSIS (SECTION 3.5) The empirical formula of any substance can be determined from its percent composition by calculating the relative number of moles of each atom in an arbitrary-sized sample (typically 100 g) of the substance. If the substance is molecular in nature, its molecular formula can be determined from the empirical formula if the molecular weight is also known. Combustion analysis is a special technique for determining the empirical formulas of compounds containing only carbon, hydrogen, and/or oxygen.

QUANTITATIVE INFORMATION FROM BALANCED EQUATIONS AND LIMITING REACTANTS (SECTIONS 3.6 AND 3.7) The mole concept can be used to calculate the relative quantities of reactants and products in chemical reactions. The coefficients in a balanced equation give the relative numbers of moles of the reactants and products. To calculate the number of grams of a product from the number of grams of a reactant, first convert grams of reactant to moles of reactant. Then use the coefficients in the balanced equation to convert the number of moles of reactant to moles of product. Finally, convert moles of product to grams of product.

A **limiting reactant** is the reactant that is completely consumed in a reaction. When it is used up, the reaction stops, thus limiting the quantities of products formed. The **theoretical yield** of a reaction is the quantity of product calculated to form when the limiting reactant is fully consumed. The actual yield of a reaction is the amount of product experimentally obtained in a reaction; it is always less than the theoretical yield. The **percent yield** is the actual yield divided by the theoretical yield, converted to a percentage.

Key Equations

- $$\text{\% mass composition of element} = \frac{\left(\begin{array}{c}\text{number of atoms}\\ \text{of element}\end{array}\right)\left(\begin{array}{c}\text{atomic weight}\\ \text{of element}\end{array}\right)}{\text{formula weight of compound}} \times 100\% \qquad [3.13]$$

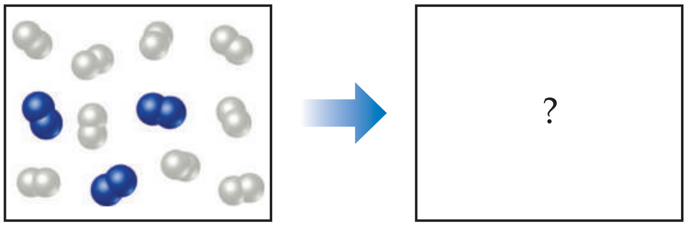
  This is the formula to calculate the mass percentage of each element in a compound. The sum of the percentages of all elements in a compound should add up to 100%.

- $$\text{Percent yield} = \frac{\text{actual yield}}{\text{theoretical yield}} \times 100\% \qquad [3.18]$$

  This is the formula to calculate the percent yield of a reaction. The percent yield can never be more than 100%.

Exam Prep

EP 3.1 In the following diagram, the white spheres represent hydrogen atoms and the blue spheres represent nitrogen atoms.



The two reactants combine to form a single product, ammonia, NH_3, which is not shown. Write a balanced chemical equation for the reaction. Based on the equation and the contents of the left (reactants) box, how many NH_3 molecules should be shown in the right (products) box? **(a)** 2 **(b)** 3 **(c)** 4 **(d)** 6 **(e)** 9

EP 3.2 The unbalanced equation for the reaction between methane and bromine is

$$\_\_CH_4(g) + \_\_Br_2(l) \longrightarrow \_\_CBr_4(s) + \_\_HBr(g)$$

Once this equation is balanced, what is the value of the coefficient in front of bromine, Br_2? **(a)** 1 **(b)** 2 **(c)** 3 **(d)** 4 **(e)** 6

EP 3.3 Which of the following reactions can be classified as a combination reaction?

(a) $2Mn_3O_4(s) \rightarrow 6MnO(s) + O_2(g)$

(b) $HCl(g) + NH_3(g) \rightarrow NH_4Cl(s)$

(c) $4NH_4ClO_4(s) \rightarrow 4HCl(g) + 2N_2(g) + 5O_2(g) + 6H_2O(g)$

(d) $2C_2H_2(g) + 3O_2(g) \rightarrow 4CO_2(g) + 2H_2O(g)$

EP 3.4 Which of the following reactions is the balanced equation that represents the decomposition reaction that occurs when silver(I) oxide is heated?

(a) $AgO(s) \longrightarrow Ag(s) + O(g)$

(b) $2AgO(s) \longrightarrow 2Ag(s) + O_2(g)$

(c) $Ag_2O(s) \longrightarrow 2Ag(s) + O(g)$

(d) $2Ag_2O(s) \longrightarrow 4Ag(s) + O_2(g)$

(e) $Ag_2O(s) \longrightarrow 2Ag(s) + O_2(g)$

EP 3.5 Write the balanced equation for the reaction that occurs when ethylene glycol, $C_2H_4(OH)_2$, burns in air.

(a) $C_2H_4(OH)_2(l) + 5O_2(g) \longrightarrow 2CO_2(g) + 3H_2O(g)$

(b) $2C_2H_4(OH)_2(l) + 5O_2(g) \longrightarrow 4CO_2(g) + 6H_2O(g)$

(c) $C_2H_4(OH)_2(l) + 3O_2(g) \longrightarrow 2CO_2(g) + 3H_2O(g)$

(d) $C_2H_4(OH)_2(l) + 5O(g) \longrightarrow 2CO_2(g) + 3H_2O(g)$

(e) $4C_2H_4(OH)_2(l) + 10O_2(g) \longrightarrow 8CO_2(g) + 12H_2O(g)$

EP 3.6 Which of the following is the correct formula weight for calcium phosphate? **(a)** 310.2 amu **(b)** 135.1 amu **(c)** 182.2 amu **(d)** 278.2 amu **(e)** 175.1 amu

EP 3.7 What is the percentage of nitrogen, by mass, in calcium nitrate? **(a)** 8.54% **(b)** 17.1% **(c)** 13.7% **(d)** 24.4% **(e)** 82.9%

EP 3.8 Which of the following samples contains the fewest sodium atoms? **(a)** 1 mol sodium oxide **(b)** 45 g sodium fluoride **(c)** 50 g sodium chloride **(d)** 1 mol sodium nitrate

EP 3.9 A sample of an ionic compound containing iron and chlorine is analyzed and found to have a molar mass of 126.8 g/mol. What is the charge of the iron in this compound? **(a)** 1+ **(b)** 2+ **(c)** 3+ **(d)** 4+

EP 3.10 How many chlorine atoms are in 12.2 g of CCl_4? **(a)** 4.77×10^{22} **(b)** 7.34×10^{24} **(c)** 1.91×10^{23} **(d)** 2.07×10^{23}

EP 3.11 Cyclohexane, a commonly used organic solvent, is 85.6% C and 14.4% H by mass with a molar mass of 84.2 g/mol. What is its molecular formula? **(a)** C_6H **(b)** CH_2 **(c)** C_5H_{24} **(d)** C_6H_{12} **(e)** C_4H_8

EP 3.12 The compound dioxane, which is used as a solvent in various industrial processes, is composed of C, H, and O atoms. Combustion of a 2.203-g sample of this compound produces 4.401 g CO_2 and 1.802 g H_2O. A separate experiment shows that it has a molar mass of 88.1 g/mol. Which of the following is the correct molecular formula for dioxane? **(a)** C_2H_4O **(b)** $C_4H_4O_2$ **(c)** CH_2 **(d)** $C_4H_8O_2$

EP 3.13 Sodium hydroxide reacts with carbon dioxide to form sodium carbonate and water:

$$2NaOH(s) + CO_2(g) \longrightarrow Na_2CO_3(s) + H_2O(l)$$

How many grams of Na_2CO_3 can be prepared from 2.40 g of NaOH? **(a)** 3.18 g **(b)** 6.36 g **(c)** 1.20 g **(d)** 0.0300 g

EP 3.14 Propane, C_3H_8, is a common fuel used for cooking and home heating. What mass of O_2 is consumed in the combustion of 1.00 g of propane? **(a)** 5.00 g **(b)** 0.726 g **(c)** 2.18 g **(d)** 3.63 g

EP 3.15 Suppose 24 mol of methanol and 15 mol of oxygen combine in the following combustion reaction:

$$2CH_3OH(l) + 3O_2(g) \longrightarrow 2CO_2(g) + 4H_2O(g)$$

What is the excess reactant, and how many moles of it remain at the end of the reaction? **(a)** 9 mol $CH_3OH(l)$ **(b)** 10 mol $CO_2(g)$ **(c)** 10 mol $CH_3OH(l)$ **(d)** 14 mol $CH_3OH(l)$ **(e)** 1 mol O_2

EP 3.16 Molten gallium reacts with arsenic to form the semiconductor gallium arsenide, GaAs, used in light emitting diodes and solar cells:

$$Ga(l) + As(s) \longrightarrow GaAs(s)$$

If 4.00 g of gallium is reacted with 5.50 g of arsenic, how many grams of the excess reactant are left at the end of the reaction? **(a)** 1.20 g As **(b)** 1.50 g As **(c)** 4.30 g As **(d)** 8.30 g Ga

EP 3.17 If 3.00 g of titanium metal is reacted with 6.00 g of chlorine gas, Cl_2, to form 7.7 g of titanium(IV) chloride in a combination reaction, what is the percent yield of the product? (**a**) 65% (**b**) 96% (**c**) 48% (**d**) 86%

EP 3.18 When a mixture of 52.0 g acetylene, C_2H_2, and 96.0 g oxygen, O_2, is ignited, the resultant combustion reaction produces CO_2 and H_2O. For this combustion reaction, the limiting reactant is ________ and the theoretical yield of CO_2 is ________. (**a**) O_2, 44.0 g (**b**) O_2, 106 g (**c**) C_2H_2, 44.0 g (**d**) C_2H_2, 88.0 g (**e**) O_2, 176 g

EP 3.19 Aluminum trichloride, $AlCl_3$, is formed from the reaction of $Al_2O_3(s)$ with HCl gas. The balanced reaction is:

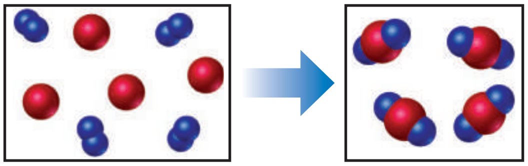
$$Al_2O_3(s) + 6HCl(g) \rightarrow 2AlCl_3(s) + 3H_2O(g)$$

When 1.50 kg of Al_2O_3 is reacted with excess HCl until it is all consumed, 2.85 kg of $AlCl_3$ are recovered after the reaction is completed. What is the percent yield for this experiment? (**a**) 48.5% (**b**) 72.6% (**c**) 80.5% (**d**) 87.3% (**e**) 95.0%

Exercises

Visualizing Concepts

3.1 The reaction between reactant A (blue spheres) and reactant B (red spheres) is shown in the following diagram:



Based on this diagram, which equation best describes the reaction? [Section 3.1]

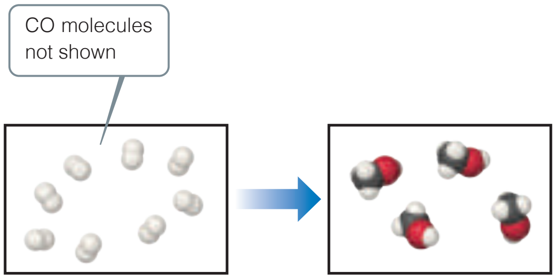
(**a**) $A_2 + B \longrightarrow A_2B$

(**b**) $A_2 + 4B \longrightarrow 2AB_2$

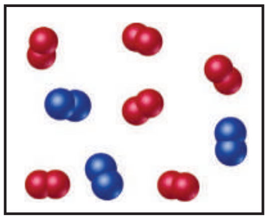
(**c**) $2A + B_4 \longrightarrow 2AB_2$

(**d**) $A + B_2 \longrightarrow AB_2$

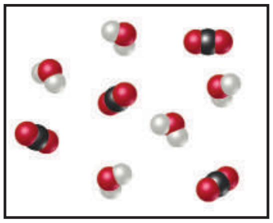
3.2 The following diagram shows the combination reaction between hydrogen, H_2, and carbon monoxide, CO, to produce methanol, CH_3OH (white spheres are H, black spheres are C, red spheres are O). The correct number of CO molecules involved in this reaction is not shown. [Section 3.1] (**a**) Determine the number of CO molecules that should be shown in the left (reactants) box. (**b**) Write a balanced chemical equation for the reaction.



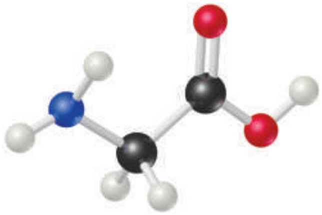
3.3 The following diagram represents the collection of elements formed by a decomposition reaction. (**a**) If the blue spheres represent N atoms and the red ones represent O atoms, what was the empirical formula of the original compound? (**b**) Is it possible to determine the molecular formula of the reactant from the identities and quantities of the products? [Section 3.2]



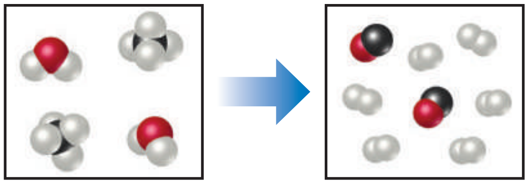
3.4 The following diagram represents the collection of CO_2 and H_2O molecules formed by complete combustion of a hydrocarbon. What is the empirical formula of the hydrocarbon? [Section 3.2]



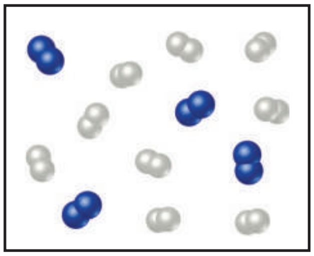
3.5 Glycine, an amino acid used by organisms to make proteins, is represented by the following molecular model. (**a**) Write its molecular formula. (**b**) Determine its molar mass. (**c**) Calculate how many moles of glycine are in a 100.0-g sample of glycine. (**d**) Calculate the percent nitrogen by mass in glycine. [Sections 3.3 and 3.5]



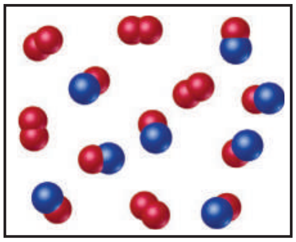
3.6 The following diagram represents a high-temperature reaction between CH_4 and H_2O. Based on this reaction, find how many moles of each product can be obtained starting with 4.0 mol CH_4. [Section 3.6]



3.7 Nitrogen (N_2) and hydrogen (H_2) react to form ammonia (NH_3). Consider the mixture of N_2 and H_2 shown in the accompanying diagram. The blue spheres represent N, and the white ones represent H. (**a**) Write the balanced chemical equation for the reaction. (**b**) What is the limiting reactant? (**c**) How many molecules of ammonia can be made, assuming the reaction goes to completion, based on the diagram? (**d**) Are any reactant molecules left over, based on the diagram? If so, how many of which type are left over? [Section 3.7]



3.8 Nitrogen monoxide and oxygen react to form nitrogen dioxide. Consider the mixture of NO and O_2 shown in the accompanying diagram. The blue spheres represent N, and the red ones represent O. (**a**) How many molecules of NO_2 can be formed, assuming the reaction goes to completion? (**b**) What is the limiting reactant? (**c**) If the actual yield of the reaction was 75% instead of 100%, how many molecules of each kind would be present after the reaction was over?



Chemical Equations (Section 3.1)

3.9 Write "true" or "false" for each statement. (**a**) We balance chemical equations as we do because energy must be conserved. (**b**) If the reaction $2\,O_3(g) \rightarrow 3\,O_2(g)$ goes to completion and all O_3 is converted to O_2, then the mass of O_3 at the beginning of the reaction must be the same as the mass of O_2 at the end of the reaction. (**c**) You can balance the "water-splitting" reaction $H_2O(l) \rightarrow H_2(g) + O_2(g)$ by writing it this way: $H_2O_2(l) \rightarrow H_2(g) + O_2(g)$.

3.10 A key step in balancing chemical equations is correctly identifying the formulas of the reactants and products. For example, consider the reaction between calcium oxide, $CaO(s)$, and $H_2O(l)$ to form aqueous calcium hydroxide. (**a**) Write a balanced chemical equation for this combination reaction, having correctly identified the product as $Ca(OH)_2(aq)$. (**b**) Is it possible to balance the equation if you incorrectly identify the product as $CaOH(aq)$, and if so, what is the equation?

3.11 Balance the following equations:

(**a**) $CO(g) + O_2(g) \longrightarrow CO_2(g)$

(**b**) $N_2O_5(g) + H_2O(l) \longrightarrow HNO_3(aq)$

(**c**) $CH_4(g) + Cl_2(g) \longrightarrow CCl_4(l) + HCl(g)$

(**d**) $Zn(OH)_2(s) + HNO_3(aq) \longrightarrow Zn(NO_3)_2(aq) + H_2O(l)$

3.12 Balance the following equations:

(**a**) $Li(s) + N_2(g) \longrightarrow Li_3N(s)$

(**b**) $TiCl_4(l) + H_2O(l) \longrightarrow TiO_2(s) + HCl(aq)$

(**c**) $NH_4NO_3(s) \longrightarrow N_2(g) + O_2(g) + H_2O(g)$

(**d**) $AlCl_3(s) + Ca_3N_2(s) \longrightarrow AlN(s) + CaCl_2(s)$

3.13 Balance the following equations:

(**a**) $Al_4C_3(s) + H_2O(l) \longrightarrow Al(OH)_3(s) + CH_4(g)$

(**b**) $C_5H_{10}O_2(l) + O_2(g) \longrightarrow CO_2(g) + H_2O(g)$

(**c**) $Fe(OH)_3(s) + H_2SO_4(aq) \longrightarrow Fe_2(SO_4)_3(aq) + H_2O(l)$

(**d**) $Mg_3N_2(s) + H_2SO_4(aq) \longrightarrow MgSO_4(aq) + (NH_4)_2SO_4(aq)$

3.14 Balance the following equations:

(**a**) $P_4O_{10}(s) + H_2O(l) \rightarrow H_3PO_4(aq)$

(**b**) $WCl_6(s) + Na_2S(s) \rightarrow WS_2(s) + NaCl(s) + S(s)$

(**c**) $NaHCO_3(s) + H_2SO_4(aq) \rightarrow CO_2(g) + H_2O(l) + Na_2SO_4(aq)$

(**d**) $NaN_3(s) + HNO_2(aq) \rightarrow N_2(g) + NO(g) + NaOH(aq)$

3.15 Write balanced chemical equations corresponding to each of the following descriptions: (**a**) Solid calcium carbide, CaC_2, reacts with water to form an aqueous solution of calcium hydroxide and acetylene gas, C_2H_2. (**b**) When solid potassium chlorate is heated, it decomposes to form solid potassium chloride and oxygen gas. (**c**) Solid zinc metal reacts with sulfuric acid to form hydrogen gas and an aqueous solution of zinc sulfate. (**d**) When liquid phosphorus trichloride is added to water, it reacts to form aqueous phosphorous acid, $H_3PO_3(aq)$, and aqueous hydrochloric acid. (**e**) When hydrogen sulfide gas is passed over solid hot iron(III) hydroxide, the resulting reaction produces solid iron(III) sulfide and gaseous water.

3.16 Write balanced chemical equations to correspond to each of the following descriptions: (**a**) When sulfur trioxide gas reacts with water, a solution of sulfuric acid forms. (**b**) Boron sulfide, $B_2S_3(s)$, reacts violently with water to form dissolved boric acid, H_3BO_3, and hydrogen sulfide gas. (**c**) Phosphine, $PH_3(g)$, combusts in oxygen gas to form water vapor and solid tetraphosphorus decaoxide. (**d**) When solid mercury(II) nitrate is heated, it decomposes to form solid mercury(II) oxide, gaseous nitrogen dioxide, and oxygen. (**e**) Copper metal reacts with hot concentrated sulfuric acid solution to form aqueous copper(II) sulfate, sulfur dioxide gas, and water.

Simple Patterns of Chemical Reactivity (Section 3.2)

3.17 (**a**) When the metallic element sodium combines with the nonmetallic element bromine, $Br_2(l)$, what is the chemical formula of the product? (**b**) Is the product a solid, liquid, or gas at room temperature? (**c**) In the balanced chemical equation for this reaction, what is the coefficient in front of the product?

3.18 (**a**) When a compound containing C, H, and O is completely combusted in air, what reactant besides the hydrocarbon is involved in the reaction? (**b**) What products form in this reaction? (**c**) What is the sum of the coefficients in the balanced chemical equation for the combustion of one mole of acetone, $C_3H_6O(l)$, in air?

3.19 Write a balanced chemical equation for the reaction that occurs when (**a**) $Mg(s)$ reacts with $Cl_2(g)$; (**b**) barium carbonate decomposes into barium oxide and carbon dioxide gas when heated; (**c**) the hydrocarbon styrene, $C_8H_8(l)$, is combusted in air; (**d**) dimethylether, $CH_3OCH_3(g)$, is combusted in air.

3.20 Write a balanced chemical equation for the reaction that occurs when (**a**) titanium metal reacts with $O_2(g)$; (**b**) silver(I) oxide decomposes into silver metal and oxygen gas when heated; (**c**) propanol, $C_3H_7OH(l)$ burns in air; (**d**) methyl *tert*-butyl ether, $C_5H_{12}O(l)$, burns in air.

3.21 Balance the following equations and indicate whether they are combination, decomposition, or combustion reactions:

(**a**) $C_3H_6(g) + O_2(g) \longrightarrow CO_2(g) + H_2O(g)$

(**b**) $NH_4NO_3(s) \longrightarrow N_2O(g) + H_2O(g)$

(**c**) $C_5H_6O(l) + O_2(g) \longrightarrow CO_2(g) + H_2O(g)$

(**d**) $N_2(g) + H_2(g) \longrightarrow NH_3(g)$

(**e**) $K_2O(s) + H_2O(l) \longrightarrow KOH(aq)$

3.22 Balance the following equations and indicate whether they are combination, decomposition, or combustion reactions:

(**a**) $PbCO_3(s) \longrightarrow PbO(s) + CO_2(g)$

(**b**) $C_2H_4(g) + O_2(g) \longrightarrow CO_2(g) + H_2O(g)$

(**c**) $Mg(s) + N_2(g) \longrightarrow Mg_3N_2(s)$

(**d**) $C_7H_8O_2(l) + O_2(g) \longrightarrow CO_2(g) + H_2O(g)$

(**e**) $Al(s) + Cl_2(g) \longrightarrow AlCl_3(s)$

Formula Weights (Section 3.3)

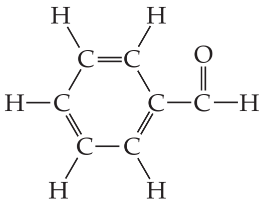
3.23 Determine the formula weights of each of the following compounds: (**a**) nitric acid, HNO_3 (**b**) $KMnO_4$ (**c**) $Ca_3(PO_4)_2$ (**d**) quartz, SiO_2 (**e**) gallium sulfide (**f**) chromium(III) sulfate (**g**) phosphorus trichloride.

3.24 Determine the formula weights of each of the following compounds: (**a**) phosgene, $COCl_2$, a colorless gas used in the manufacture of some plastics and as a chemical warfare agent during World War I (**b**) citric acid, $C_6H_8O_7$, a weak acid prevalent in citrus fruits (**c**) hydroxyapatite, $Ca_{10}(PO_4)_6(OH)_2$, the principal component of human bones (**d**) myrcene, $C_{10}H_{16}$, an aromatic molecule found in herbs and spices such as thyme, hops, cannabis, and cardamom (**e**) benzaldehyde, C_6H_5CHO, the molecule largely responsible for the odor of almond extract.

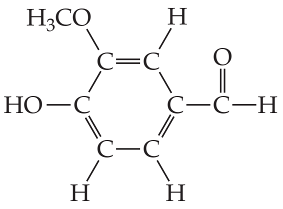
3.25 Calculate the percentage by mass of oxygen in the following compounds: (**a**) morphine, $C_{17}H_{19}NO_3$ (**b**) codeine, $C_{18}H_{21}NO_3$ (**c**) cocaine, $C_{17}H_{21}NO_4$ (**d**) tetracycline, $C_{22}H_{24}N_2O_8$ (**e**) digitoxin, $C_{41}H_{64}O_{13}$ (**f**) vancomycin, $C_{66}H_{75}Cl_2N_9O_{24}$

3.26 Calculate the percentage by mass of the indicated element in the following compounds: (**a**) carbon in acetylene, C_2H_2, a gas used in welding (**b**) hydrogen in ascorbic acid, $HC_6H_7O_6$, also known as vitamin C (**c**) hydrogen in ammonium sulfate, $(NH_4)_2SO_4$, a substance used as a nitrogen fertilizer (**d**) platinum in $PtCl_2(NH_3)_2$, a chemotherapy agent called cisplatin (**e**) oxygen in the female sex hormone estradiol, $C_{18}H_{24}O_2$ (**f**) carbon in capsaicin, $C_{18}H_{27}NO_3$, the compound that gives the hot taste to chili peppers.

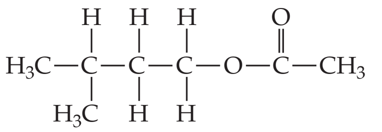
3.27 Based on the following structural formulas, calculate the percentage of carbon by mass present in each compound:

(**a**)


Benzaldehyde
(almond fragrance)

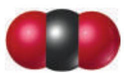
(**b**)


Vanillin
(vanilla flavor)

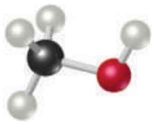
(**c**)


Isopentyl acetate
(banana flavor)

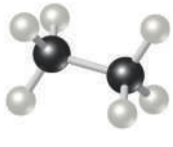
3.28 Calculate the percentage of carbon by mass in each of the compounds represented by the following models:



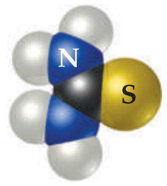
(**a**)



(**b**)



(**c**)



(**d**)

Avogadro's Number and the Mole (Section 3.4)

3.29 Characterize the following statements as either true or false. (**a**) A mole of horses contains a mole of horse legs. (**b**) A mole of water has a mass of 18.0 g. (**c**) The mass of one molecule of water is 18.0 g. (**d**) A mole of NaCl(*s*) contains two moles of ions.

3.30 (**a**) What is the mass, in grams, of 1 mol of ^{12}C? (**b**) How many carbon atoms are present in 1 mol of ^{12}C?

3.31 Without doing any detailed calculations (but using a periodic table to give atomic weights), rank the following samples in order of increasing numbers of atoms: 0.50 mol H_2O, 23 *g* Na, 6.0×10^{23} N_2 molecules.

3.32 Without doing any detailed calculations (but using a periodic table to give atomic weights), rank the following samples in order of increasing numbers of atoms: 42 *g* of $NaHCO_3$, 1.5 mol CO_2, 6.0×10^{24} Ne atoms.

3.33 What is the mass, in kilograms, of an Avogadro's number of people, if the average mass of a person is 73 kg? How does this compare with the mass of Earth, 5.98×10^{24} kg?

3.34 If an Avogadro's number of pennies is divided equally among the 321 million men, women, and children in the United States, how many dollars would each receive? How does this compare with the gross domestic product (GDP) of the United States, which was $21.4 trillion in 2019? (GDP is the total market value of the nation's goods and services.)

3.35 Calculate the following quantities:

(**a**) mass, in grams, of 0.105 mol sucrose ($C_{12}H_{22}O_{11}$)

(**b**) moles of $Zn(NO_3)_2$ in 143.50 g of this substance

(**c**) number of molecules in 1.0×10^{-6} mol CH_3CH_2OH

(**d**) number of N atoms in 0.410 mol NH_3

3.36 Calculate the following quantities:

(**a**) mass, in grams, of 1.50×10^{-2} mol CdS

(**b**) number of moles of NH_4Cl in 86.6 g of this substance

(**c**) number of molecules in 8.447×10^{-2} mol C_6H_6

(**d**) number of O atoms in 6.25×10^{-3} mol $Al(NO_3)_3$

3.37 (**a**) What is the mass, in grams, of 2.50×10^{-3} mol of ammonium phosphate?

(**b**) How many moles of chloride ions are in 0.2550 g of aluminum chloride?

(**c**) What is the mass, in grams, of 7.70×10^{20} molecules of caffeine, $C_8H_{10}N_4O_2$?

(**d**) What is the molar mass of cholesterol if 0.00105 mol has a mass of 0.406 g?

3.38 (**a**) What is the mass, in grams, of 1.223 mol of iron(III) sulfate?

(**b**) How many moles of ammonium ions are in 6.955 g of ammonium carbonate?

(**c**) What is the mass, in grams, of 1.50×10^{21} molecules of aspirin, $C_9H_8O_4$?

(**d**) What is the molar mass of diazepam (Valium®) if 0.05570 mol has a mass of 15.86 g?

3.39 The molecular formula of allicin, the compound responsible for the characteristic smell of garlic, is $C_6H_{10}OS_2$. (**a**) What is the molar mass of allicin? (**b**) How many moles of allicin are present in 5.00 mg of this substance? (**c**) How many molecules of allicin are in 5.00 mg of this substance? (**d**) How many S atoms are present in 5.00 mg of allicin?

3.40 The molecular formula of aspartame, the artificial sweetener marketed as NutraSweet®, is $C_{14}H_{18}N_2O_5$. (**a**) What is the molar mass of aspartame? (**b**) How many moles of aspartame are present in 1.00 mg of aspartame? (**c**) How many molecules of aspartame are present in 1.00 mg of aspartame? (**d**) How many hydrogen atoms are present in 1.00 mg of aspartame?

3.41 A sample of glucose, $C_6H_{12}O_6$, contains 1.250×10^{21} carbon atoms. (**a**) How many atoms of hydrogen does it contain? (**b**) How many molecules of glucose does it contain? (**c**) How many moles of glucose does it contain? (**d**) What is the mass of this sample in grams?

3.42 A sample of the male sex hormone testosterone, $C_{19}H_{28}O_2$, contains 3.88×10^{21} hydrogen atoms. (**a**) How many atoms of carbon does it contain? (**b**) How many molecules of testosterone does it contain? (**c**) How many moles of testosterone does it contain? (**d**) What is the mass of this sample in grams?

3.43 The allowable concentration level of vinyl chloride, C_2H_3Cl, in the atmosphere in a chemical plant is 2.0×10^{-6} g/L. How many moles of vinyl chloride in each liter does this represent? How many molecules per liter?

3.44 At least 25 μg of tetrahydrocannabinol (THC), the active ingredient in marijuana, is required to produce intoxication. The molecular formula of THC is $C_{21}H_{30}O_2$. How many moles of THC does this 25 μg represent? How many molecules?

Empirical Formulas from Analyses (Section 3.5)

3.45 Give the empirical formula of each of the following compounds if a sample contains (**a**) 0.0130 mol C, 0.0390 mol H, and 0.0065 mol O (**b**) 11.66 g iron and 5.01 g oxygen (**c**) 40.0% C, 6.7% H, and 53.3% O by mass.

3.46 Determine the empirical formula of each of the following compounds if a sample contains (**a**) 0.104 mol K, 0.052 mol C, and 0.156 mol O; (**b**) 5.28 g Sn and 3.37 g F; (**c**) 87.5% N and 12.5% H by mass.

3.47 Determine the empirical formulas of the compounds with the following compositions by mass: (**a**) 10.4% C, 27.8% S, and 61.7% Cl (**b**) 21.7% C, 9.6% O, and 68.7% F (**c**) 32.79% Na, 13.02% Al, and the remainder F

3.48 Determine the empirical formulas of the compounds with the following compositions by mass: (**a**) 55.3% K, 14.6% P, and 30.1% O (**b**) 24.5% Na, 14.9% Si, and 60.6% F (**c**) 62.1% C, 5.21% H, 12.1% N, and the remainder O

3.49 A compound whose empirical formula is XF_3 consists of 65% F by mass. What is the atomic mass of X?

3.50 The compound XCl_4 contains 75.0% Cl by mass. What is the element X?

3.51 What is the molecular formula of each of the following compounds?

(**a**) empirical formula CH_2, molar mass = 84.0 g/mol

(**b**) empirical formula NH_2Cl, molar mass = 51.5 g/mol

3.52 What is the molecular formula of each of the following compounds?

(**a**) empirical formula HCO_2, molar mass = 90.0 g/mol

(**b**) empirical formula C_2H_4O, molar mass = 88.0 g/mol

3.53 Determine the empirical and molecular formulas of each of the following substances: (**a**) Styrene, a compound used to make Styrofoam® cups and insulation, contains 92.3% C and 7.7% H by mass and has a molar mass of 104 g/mol. (**b**) Caffeine, a stimulant found in coffee, contains 49.5% C, 5.15% H, 28.9% N, and 16.5% O by mass and has a molar mass of 195 g/mol. (**c**) Monosodium glutamate (MSG), a flavor enhancer in certain foods, contains 35.51% C, 4.77% H, 37.85% O, 8.29% N, and 13.60% Na, and has a molar mass of 169 g/mol.

3.54 Determine the empirical and molecular formulas of each of the following substances: (**a**) Ibuprofen, a headache remedy, contains 75.69% C, 8.80% H, and 15.51% O by mass and has a molar mass of 206 g/mol. (**b**) Cadaverine, a foul-smelling substance produced by the action of bacteria on meat, contains 58.55% C, 13.81% H, and 27.40% N by mass; its molar mass is 102.2 g/mol. (**c**) Epinephrine (adrenaline), a hormone secreted into the bloodstream in times of danger or stress, contains 59.0% C, 7.1% H, 26.2% O, and 7.7% N by mass; its molar mass is about 180 amu.

3.55 (**a**) Combustion analysis of toluene, a common organic solvent, gives 5.86 mg of CO_2 and 1.37 mg of H_2O. If the compound contains only carbon and hydrogen, what is its empirical formula? (**b**) Menthol, the substance we can smell in mentholated cough drops, is composed of C, H, and O. A 0.1005-g sample of menthol is combusted, producing 0.2829 g of CO_2 and 0.1159 g of H_2O. What is the empirical formula for menthol? If menthol has a molar mass of 156 g/mol, what is its molecular formula?

3.56 (**a**) The characteristic odor of pineapple is due to ethyl butyrate, a compound containing carbon, hydrogen, and oxygen. Combustion of 2.78 mg of ethyl butyrate produces 6.32 mg of CO_2 and 2.58 mg of H_2O. What is the empirical formula of the compound? (**b**) Nicotine, a component of tobacco, is composed of C, H, and N. A 5.250-mg sample of nicotine was combusted, producing 14.242 mg of CO_2 and 4.083 mg of H_2O. What is the empirical formula for nicotine? If nicotine has a molar mass of 160 ± 5 g/mol, what is its molecular formula?

3.57 Valproic acid, used to treat seizures and bipolar disorder, is composed of C, H, and O. A 0.165-g sample is combusted to produce 0.166 g of water and 0.403 g of carbon dioxide. What is the empirical formula for valproic acid? If the molar mass is 144 g/mol, what is the molecular formula?

3.58 Propenoic acid, $C_3H_4O_2$, is a reactive organic liquid that is used in the manufacturing of plastics, coatings, and adhesives. An unlabeled container is thought to contain this liquid. A 0.275-g sample of the liquid is combusted to produce 0.102 g of water and 0.374 g carbon dioxide. Is the unknown liquid propenoic acid? Support your reasoning with calculations.

3.59 Washing soda, a compound used to prepare hard water for washing laundry, is a hydrate, which means that a certain number of water molecules are included in the solid structure. Its formula can be written as $Na_2CO_3 \cdot xH_2O$, where x is the number of moles of H_2O per mole of Na_2CO_3. When a 2.558-g sample of washing soda is heated at 125 °C, all the water of hydration is lost, leaving 0.948 g of Na_2CO_3. What is the value of x?

3.60 Epsom salts, a strong laxative used in veterinary medicine, is a hydrate, which means that a certain number of water molecules are included in the solid structure. The formula for Epsom salts can be written as $MgSO_4 \cdot xH_2O$, where x indicates the number of moles of H_2O per mole of $MgSO_4$. When 5.061 g of this hydrate is heated to 250 °C, all the water of hydration is lost, leaving 2.472 g of $MgSO_4$. What is the value of x?

Quantitative Information from Balanced Equations (Section 3.6)

3.61 Hydrofluoric acid, HF(*aq*), cannot be stored in glass bottles because compounds called silicates in the glass are attacked by the HF(*aq*). Sodium silicate (Na_2SiO_3), for example, reacts as follows:

$$Na_2SiO_3(s) + 8HF(aq) \longrightarrow H_2SiF_6(aq) + 2NaF(aq) + 3H_2O(l)$$

(**a**) How many moles of HF are needed to react with 0.300 mol of Na_2SiO_3? (**b**)How many grams of NaF form when 0.500 mol of HF reacts with excess Na_2SiO_3? (**c**) How many grams of Na_2SiO_3 can react with 0.800 g of HF?

3.62 The reaction between potassium superoxide, KO_2, and CO_2,

$$4KO_2 + 2CO_2 \longrightarrow 2K_2CO_3 + 3O_2$$

is used as a source of O_2 and an absorber of CO_2 in self-contained breathing equipment used by rescue workers.

(**a**) How many moles of O_2 are produced when 0.400 mol of KO_2 react in this fashion? (**b**) How many grams of KO_2 are needed to form 7.50 g of O_2? (**c**) How many grams of CO_2 are used when 7.50 g of O_2 are produced?

3.63 Several brands of antacids use $Al(OH)_3$ to react with stomach acid, which contains primarily HCl:

$$Al(OH)_3(s) + HCl(aq) \longrightarrow AlCl_3(aq) + H_2O(l)$$

(**a**) Balance this equation. (**b**) Calculate the number of grams of HCl that can react with 0.500 g of $Al(OH)_3$. (**c**) Calculate the number of grams of $AlCl_3$ and the number of grams of H_2O formed in part (a). (**d**) Show that your calculations in parts (b) and (c) are consistent with the law of conservation of mass.

3.64 An iron ore sample contains Fe_2O_3 together with other substances. Reaction of the ore with CO produces iron metal:

$$Fe_2O_3(s) + CO(g) \longrightarrow Fe(s) + CO_2(g)$$

(**a**) Balance this equation. (**b**) Calculate the number of grams of CO that can react with 0.350 kg of Fe_2O_3. (**c**) Calculate the number of grams of Fe and the number of grams of CO_2 formed when 0.350 kg of Fe_2O_3 reacts. (**d**) Show that your calculations in parts (b) and (c) are consistent with the law of conservation of mass.

3.65 Aluminum sulfide reacts with water to form aluminum hydroxide and hydrogen sulfide. (**a**) Write the balanced chemical equation for this reaction. (**b**) How many grams of aluminum hydroxide are obtained from 14.2 g of aluminum sulfide?

3.66 Calcium hydride reacts with water to form calcium hydroxide and hydrogen gas. (**a**) Write a balanced chemical equation for the reaction. (**b**) How many grams of calcium hydride are needed to form 4.500 g of hydrogen?

3.67 Automotive air bags inflate when sodium azide, NaN_3, rapidly decomposes to its component elements:

$$2NaN_3(s) \longrightarrow 2Na(s) + 3N_2(g)$$

(**a**) How many moles of N_2 are produced by the decomposition of 1.50 mol of NaN_3? (**b**) How many grams of NaN_3 are required to form 10.0 g of nitrogen gas? (**c**) How many grams of NaN_3 are required to produce 10.0 ft^3 of nitrogen gas, about the size of an automotive air bag, if the gas has a density of 1.25 g/L?

3.68 The complete combustion of octane, C_8H_{18}, a component of gasoline, proceeds as follows:

$$2C_8H_{18}(l) + 25O_2(g) \longrightarrow 16CO_2(g) + 18H_2O(g)$$

(**a**) How many moles of O_2 are needed to burn 1.50 mol of C_8H_{18}? (**b**) How many grams of O_2 are needed to burn 10.0 g of C_8H_{18}? (**c**) Octane has a density of 0.692 g/mL at 20°C. How many grams of O_2 are required to burn 15.0 gal of C_8H_{18} (the capacity of an average fuel tank)? (**d**) How many grams of CO_2 are produced when 15.0 gal of C_8H_{18} are combusted?

3.69 A piece of aluminum foil 1.00 cm^2 and 0.550-mm thick is allowed to react with bromine to form aluminum bromide.

(**a**) How many moles of aluminum were used? (The density of aluminum is 2.699 g/cm^3.) (**b**) Write a balanced chemical equation for this reaction. (**c**) How many grams of aluminum bromide form, assuming the aluminum reacts completely?

3.70 Detonation of nitroglycerin proceeds as follows:

$$4C_3H_5N_3O_9(l) \longrightarrow 12CO_2(g) + 6N_2(g) + O_2(g) + 10H_2O(g)$$

(**a**) If a sample containing 2.00 mL of nitroglycerin (density = 1.592 g/mL) is detonated, how many moles of gas are produced? (**b**) If each mole of gas occupies 55 L under the conditions of the explosion, how many liters of gas are produced? (**c**) How many grams of N_2 are produced in the detonation?

3.71 The combustion of one mole of liquid ethanol, CH_3CH_2OH, produces 1367 kJ of heat. (**a**) Write a balanced chemical equation for the combustion of ethanol. (**b**) Calculate how much heat is produced when 235.0 g of ethanol are combusted.

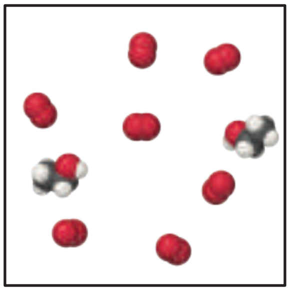
3.72 The combustion of one mole of liquid octane, $CH_3(CH_2)_6CH_3$, produces 5470 kJ of heat. (**a**) Write a balanced chemical equation for the combustion of octane. (**b**) Calculate how much heat is produced if 1.000 gallon of octane is combusted. Octane has a density of 0.692 g/mL at 20°C.

Limiting Reactants (Section 3.7)

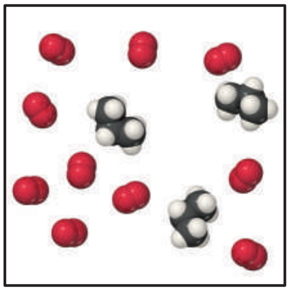
3.73 Imagine you were asked to assemble skateboards from decks, axles, and wheels, with each skateboard made from one deck, two axles, and four wheels. (**a**) What is the limiting reactant if you start from 25 decks, 48 axles, and 106 wheels? (**b**) What is the theoretical yield of skateboards? (**c**) If 22 boards are produced once the assembly is complete, what is the percent yield of skateboards?

3.74 Consider a recipe for making a club sandwich that consists of three slices toasted bread, 2 slices turkey breast, 2 pieces fried bacon, and one slice cheddar cheese. (**a**) If you start with 36 slices of bread, 20 slices of turkey breast, 24 pieces bacon, and 14 slices of cheese, what is the limiting reactant? (**b**) What is the theoretical yield of club sandwiches? (**c**) If you ask your roommate to prepare club sandwiches for a party and they finish with nine sandwiches, what is the percent yield of sandwiches?

3.75 Consider the mixture of ethanol, C_2H_5OH, and O_2 shown in the accompanying diagram. (**a**) Write a balanced equation for the combustion reaction that occurs between ethanol and oxygen. (**b**) Which reactant is the limiting reactant? (**c**) How many molecules of CO_2, H_2O, C_2H_5OH, and O_2 will be present if the reaction goes to completion?



3.76 Consider the mixture of propane, C_3H_8, and O_2 shown here. (**a**) Write a balanced equation for the combustion reaction that occurs between propane and oxygen. (**b**) Which reactant is the limiting reactant? (**c**) How many molecules of CO_2, H_2O, C_3H_8, and O_2 will be present if the reaction goes to completion?



3.77 Sodium hydroxide reacts with carbon dioxide as follows:

$$2NaOH(s) + CO_2(g) \longrightarrow Na_2CO_3(s) + H_2O(l)$$

Which is the limiting reactant when 1.85 mol NaOH and 1.00 mol CO_2 are allowed to react? How many moles of Na_2CO_3 can be produced? How many moles of the excess reactant remain after the completion of the reaction?

3.78 Aluminum hydroxide reacts with sulfuric acid as follows:

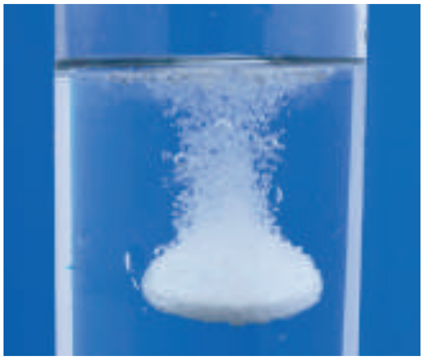
$$2Al(OH)_3(s) + 3H_2SO_4(aq) \longrightarrow Al_2(SO_4)_3(aq) + 6H_2O(l)$$

Which is the limiting reactant when 0.500 mol $Al(OH)_3$ and 0.500 mol H_2SO_4 are allowed to react? How many moles of $Al_2(SO_4)_3$ can form under these conditions? How many moles of the excess reactant remain after completion of the reaction?

3.79 The fizz produced when an Alka-Seltzer tablet is dissolved in water is due to the reaction between sodium bicarbonate ($NaHCO_3$) and citric acid ($H_3C_6H_5O_7$):

$$3NaHCO_3(aq) + H_3C_6H_5O_7(aq) \longrightarrow 3CO_2(g) + 3H_2O(l) + Na_3C_6H_5O_7(aq)$$

In a certain experiment, 1.00 g of sodium bicarbonate and 1.00 g of citric acid are allowed to react. (**a**) Which is the limiting reactant? (**b**) How many grams of carbon dioxide form? (**c**) How many grams of the excess reactant remain after the limiting reactant is completely consumed?



3.80 One of the steps in the commercial process for converting ammonia to nitric acid is the conversion of NH_3 to NO:

$$4NH_3(g) + 5O_2(g) \longrightarrow 4NO(g) + 6H_2O(g)$$

In a certain experiment, 2.00 g of NH_3 reacts with 2.50 g of O_2. (**a**) Which is the limiting reactant? (**b**) How many grams of NO and H_2O form? (**c**) How many grams of the excess reactant remain after the limiting reactant is completely consumed? (**d**) Show that your calculations in parts (**b**) and (**c**) are consistent with the law of conservation of mass.

3.81 Solutions of sodium carbonate and silver nitrate react to form solid silver carbonate and a solution of sodium nitrate. A solution containing 3.50 g of sodium carbonate is mixed with a solution containing 5.00 g of silver nitrate. How many grams of sodium carbonate, silver nitrate, silver carbonate, and sodium nitrate are present after the reaction is complete?

3.82 Solutions of sulfuric acid and lead(II) acetate react to form solid lead(II) sulfate and a solution of acetic acid. If 5.00 g of sulfuric acid and 5.00 g of lead(II) acetate are mixed, calculate the number of grams of sulfuric acid, lead(II) acetate, lead(II) sulfate, and acetic acid present in the mixture after the reaction is complete.

3.83 When benzene (C_6H_6) reacts with bromine (Br_2), bromobenzene (C_6H_5Br) is obtained:

$$C_6H_6 + Br_2 \longrightarrow C_6H_5Br + HBr$$

(**a**) When 30.0 g of benzene reacts with 65.0 g of bromine, what is the theoretical yield of bromobenzene? (**b**) If the actual yield of bromobenzene is 42.3 g, what is the percentage yield?

3.84 When ethane (C_2H_6) reacts with chlorine (Cl_2), the main product is C_2H_5Cl, but other products containing Cl, such as $C_2H_4Cl_2$, are also obtained in small quantities. The formation of these other products reduces the yield of C_2H_5Cl. (**a**) Calculate the theoretical yield of C_2H_5Cl when 125 g of C_2H_6 reacts with 255 g of Cl_2, assuming that C_2H_6 and Cl_2 react only to form C_2H_2Cl and HCl. (**b**) Calculate the percent yield of C_2H_5Cl if the reaction produces 206 g of C_2H_5Cl.

3.85 Hydrogen sulfide is an impurity in natural gas that must be removed. One common removal method is called the Claus process, which relies on the reaction:

$$8\,H_2S(g) + 4\,O_2(g) \longrightarrow S_8(l) + 8\,H_2O(g)$$

Under optimal conditions, the Claus process gives 98% yield of S_8 from H_2S. If you started with 30.0 g of H_2S and 50.0 g of O_2, how many grams of S_8 would be produced, assuming 98% yield?

3.86 When hydrogen sulfide gas is bubbled into a solution of sodium hydroxide, the reaction forms sodium sulfide and water. How many grams of sodium sulfide are formed if 1.25 g of hydrogen sulfide is bubbled into a solution containing 2.00 g of sodium hydroxide, assuming that the sodium sulfide is made in 92.0% yield?

Additional Exercises

3.87 Write the balanced chemical equations for (**a**) the complete combustion of acetic acid (CH_3COOH), the main ingredient in vinegar; (**b**) the decomposition of solid calcium hydroxide into solid calcium oxide (lime) and water vapor; (**c**) the combination reaction between nickel metal and chlorine gas.

3.88 The effectiveness of nitrogen fertilizers depends on both their ability to deliver nitrogen to plants and the amount of nitrogen they can deliver. Four common nitrogen-containing fertilizers are ammonia, ammonium nitrate, ammonium sulfate, and urea $[(NH_2)_2CO]$. Rank these fertilizers in terms of the mass percentage nitrogen they contain.

3.89 (**a**) The molecular formula of acetylsalicylic acid (aspirin), one of the most common pain relievers, is $C_9H_8O_4$. How many moles of $C_9H_8O_4$ are in a 0.500-g tablet of aspirin? Assume the tablet is composed entirely of aspirin. (**b**) How many molecules of $C_9H_8O_4$ are in this tablet? (**c**) How many carbon atoms are in the tablet?

3.90 (**a**) One molecule of the antibiotic penicillin G has a mass of 5.342×10^{-21} g. What is the molar mass of penicillin G? (**b**) Hemoglobin, the oxygen-carrying protein in red blood cells, has four iron atoms per molecule and contains 0.340% iron by mass. Calculate the molar mass of hemoglobin.

3.91 Serotonin is a compound that conducts nerve impulses in the brain. It contains 68.2% C, 6.86% H, 15.9% N, and 9.08% O. Its molar mass is 176 g/mol. Determine its molecular formula.

3.92 The koala dines exclusively on eucalyptus leaves. Its digestive system detoxifies the eucalyptus oil, a poison to other animals. The chief constituent in eucalyptus oil is a substance called eucalyptol, which contains 77.87% C, 11.76% H, and the remainder O. (**a**) What is the empirical formula for this substance? (**b**) A mass spectrum of eucalyptol shows a peak at about 154 amu. What is the molecular formula of the substance?

3.93 Vanillin, the dominant flavoring in vanilla, contains C, H, and O. When 1.05 g of this substance is completely combusted, 2.43 g of CO_2 and 0.50 g of H_2O are produced. What is the empirical formula of vanillin?

3.94 An organic compound was found to contain only C, H, and Cl. When a 1.50-g sample of the compound was completely combusted in air, 3.52 g of CO_2 was formed. In a separate experiment, the chlorine in a 1.00-g sample of the compound was converted to 1.27 g of AgCl. Determine the empirical formula of the compound.

3.95 A compound, $KBrO_x$, where x is unknown, is analyzed and found to contain 52.92% Br. What is the value of x?

3.96 An element X forms an iodide (XI_3) and a chloride (XCl_3). The iodide is quantitatively converted to the chloride when it is heated in a stream of chlorine:

$$2\,XI_3 + 3\,Cl_2 \longrightarrow 2\,XCl_3 + 3\,I_2$$

If 0.5000 g of XI_3 is treated with chlorine, 0.2360 g of XCl_3 is obtained. (**a**) Calculate the atomic weight of the element X. (**b**) Identify the element X.

3.97 A method used by the U.S. Environmental Protection Agency (EPA) for determining the concentration of ozone in air is to pass the air sample through a "bubbler" containing sodium iodide, which removes the ozone according to the following equation:

$$O_3(g) + 2\,NaI(aq) + H_2O(l) \longrightarrow O_2(g) + I_2(s) + 2\,NaOH(aq)$$

(**a**) How many moles of sodium iodide are needed to remove 5.95×10^{-6} mol of O_3? (**b**) How many grams of sodium iodide are needed to remove 1.3 mg of O_3?

3.98 A chemical plant uses electrical energy to decompose aqueous solutions of NaCl to give Cl_2, H_2, and NaOH:

$$2\,NaCl(aq) + 2\,H_2O(l) \longrightarrow 2\,NaOH(aq) + H_2(g) + Cl_2(g)$$

If the plant produces 1.5×10^6 kg (1500 metric tons) of Cl_2 daily, estimate the quantities of H_2 and NaOH produced.

3.99 The fat stored in a camel's hump is a source of both energy and water. Calculate the mass of H_2O produced by the metabolism of 1.0 kg of fat, assuming the fat consists entirely of tristearin ($C_{57}H_{110}O_6$), a typical animal fat, and assuming that during metabolism, tristearin reacts with O_2 to form only CO_2 and H_2O.

3.100 When hydrocarbons are burned in a limited amount of air, both CO and CO_2 form. When 0.450 g of a particular hydrocarbon was burned in air, 0.467 g of CO, 0.733 g of CO_2, and 0.450 g of H_2O were formed. (**a**) What is the empirical formula of the compound? (**b**) How many grams of O_2 were used in the reaction? (**c**) How many grams would have been required for complete combustion?

3.101 A mixture of $N_2(g)$ and $H_2(g)$ reacts in a closed container to form ammonia, $NH_3(g)$. The reaction ceases before either reactant has been totally consumed. At this stage 3.0 mol N_2, 3.0 mol H_2, and 3.0 mol NH_3 are present. How many moles of N_2 and H_2 were present originally?

3.102 A mixture containing $KClO_3$, K_2CO_3, $KHCO_3$, and KCl was heated, producing CO_2, O_2, and H_2O gases according to the following equations:

$$2\,KClO_3(s) \longrightarrow 2\,KCl(s) + 3\,O_2(g)$$
$$2\,KHCO_3(s) \longrightarrow K_2O(s) + H_2O(g) + 2\,CO_2(g)$$
$$K_2CO_3(s) \longrightarrow K_2O(s) + CO_2(g)$$

The KCl does not react under the conditions of the reaction. If 100.0 g of the mixture produces 1.80 g of H_2O, 13.20 g of CO_2, and 4.00 g of O_2, what was the composition of the original mixture? (Assume complete decomposition of the mixture.)

3.103 When a mixture of 10.0 g of acetylene (C_2H_2) and 10.0 g of oxygen (O_2) is ignited, the resulting combustion reaction produces CO_2 and H_2O. (**a**) Write the balanced chemical equation for this reaction. (**b**) Which is the limiting reactant? (**c**) How many grams of C_2H_2, O_2, CO_2, and H_2O are present after the reaction is complete?

3.104 (**a**) If an automobile travels 225 mi with a gas mileage of 20.5 mi/gal, how many kilograms of CO_2 are produced? Assume that the gasoline is composed of octane, $C_8H_{18}(l)$, whose density is 0.692 g/mL. (**b**) Repeat the calculation for a truck that has a gas mileage of 5 mi/gal.

3.105 (**a**) What is the theoretical yield of CO_2 if 1.00×10^3 kg (1 metric ton) of CaO is obtained by thermal decomposition of $CaCO_3$? (**b**) In ordinary Portland cement, the average CaO content of the clinker (the inorganic part of the dried cement prior to adding gypsum and any additives or fillers) is 63.5%. What quantity of CO_2 is emitted to produce 1.00×10^3 kg of clinker? (**c**) If the clinker makes up 95% of the mass of the cement, a good estimate for most cement produced in the twentieth century, what quantity of CO_2 is emitted in the production of 1.00×10^3 kg of cement? (**d**) In some parts of the world waste products, blast furnace slag from the manufacture of steel, or fly ash from coal-fired power plants are added to cement to reduce the amount of clinker in the cement. If the clinker makes up only 60% of the cement by mass, what quantity of CO_2 is emitted in the production of 1.00×10^3 kg of cement?

3.106 A particular coal contains 2.5% sulfur by mass. When this coal is burned at a power plant, the sulfur is converted into sulfur dioxide gas, which is a pollutant. To reduce sulfur dioxide emissions, calcium oxide (lime) is used. The sulfur dioxide reacts with calcium oxide to form solid calcium sulfite. (**a**) Write the balanced chemical equation for the reaction. (**b**) If the coal is burned in a power plant that uses 2000.0 tons of coal per day, what mass of calcium oxide is required daily to eliminate the sulfur dioxide? (**c**) How many grams of calcium sulfite does this power plant produce daily?

3.107 Two key components of cement clinker are Ca_3SiO_5, called tricalcium silicate or alite, and Ca_2SiO_4, called dicalcium silicate or belite. Both are formed when CaO produced from thermal decomposition of limestone ($CaCO_3$) reacts with SiO_2 present in the clays and other raw materials used to make cement. When water is added, both react to form hydrated phases that give cement much of its strength, though alite forms more rapidly and plays a more important role in the setting of the cement and its initial strength gain. (**a**) What is the mass percent Ca in alite? (**b**) What is the mass percent Ca in belite? (**c**) As the belite composition of cement increases, would it increase or decrease the quantity of CO_2 emitted in producing cement?

3.108 The source of oxygen that drives the internal combustion engine in an automobile is air. Air is a mixture of gases, principally N_2(~79%) and O_2(~20%). In the cylinder of an automobile engine, nitrogen can react with oxygen to produce nitric oxide gas, NO. As NO is emitted from the tailpipe of the car, it can react with more oxygen to produce nitrogen dioxide gas. (**a**) Write balanced chemical equations for both reactions. (**b**) Both nitric oxide and nitrogen dioxide are pollutants that can lead to acid rain and global warming; collectively, they are called NO_x gases. In 2009, the United States emitted an estimated 19 million tons of nitrogen dioxide into the atmosphere. How many grams of nitrogen dioxide is this? (**c**) The production of NO_x gases is an unwanted side reaction of the main engine combustion process that turns octane, C_8H_{18}, into CO_2 and water. If 85% of the oxygen in an engine is used to combust octane and the remainder is used to produce nitrogen dioxide, calculate how many grams of nitrogen dioxide would be produced during the combustion of 500 g of octane.

Design an Experiment

You will learn later in this book that sulfur is capable of forming two common oxides, SO_2 and SO_3. One question that we might ask is whether the direct reaction between sulfur and oxygen leads to the formation of SO_2, SO_3, or a mixture of the two. This question has practical significance because SO_3 can go on to react with water to form sulfuric acid, H_2SO_4, which is produced industrially on a very large scale. Consider also that the answer to this question may depend on the relative amount of each element that is present and the temperature at which the reaction is carried out. For example, on the one hand, carbon and oxygen normally react to form CO_2, but when not enough oxygen is present, CO can form. On the other hand, under normal reaction conditions, H_2 and O_2 react to form water, H_2O (rather than hydrogen peroxide H_2O_2), regardless of the starting ratio of hydrogen to oxygen.

Suppose you are given a bottle of sulfur, which is a yellow solid, a cylinder of O_2, a transparent reaction vessel that can be evacuated and sealed so that only sulfur, oxygen, and the product(s) of the reaction between the two are present, an analytical balance so that you can determine the masses of the reactants and/or products, and a furnace that can be used to heat the reaction vessel to 200°C where the two elements react. (**a**) If you start with 0.10 mol of sulfur in the reaction vessel, how many moles of oxygen would need to be added to form SO_2, assuming SO_2 forms exclusively? (**b**) How many moles of oxygen would be needed to form SO_3, assuming SO_3 forms exclusively? (**c**) Given the available equipment, how would you determine you had added the correct number of moles of each reactant to the reaction vessel? (**d**) What observation or experimental technique would you use to determine the identity of the reaction product(s)? Could differences in the physical properties of SO_2 and SO_3 be used to help identify the product(s)? Have any instruments been described in Chapters 1–3 that would allow you to identify the product(s)? (**e**) What experiments would you conduct to determine if the product(s) of this reaction (either SO_2 or SO_3 or a mixture of the two) can be controlled by varying the ratio of sulfur and oxygen that are added to the reaction vessel? What ratio(s) of S to O_2 would you test to answer this question?

4

REACTIONS IN AQUEOUS SOLUTION

▲ Seawater is a complex aqueous solution.

WHAT'S AHEAD

4.1 ▶ General Properties of Aqueous Solutions Recognize that substances dissolved in water exist as ions, molecules, or a mixture of the two.

4.2 ▶ Precipitation Reactions Identify reactions in which soluble reactants yield an insoluble product.

4.3 ▶ Acids, Bases, and Neutralization Reactions Explore reactions in which protons, H^+ ions, are transferred from one reactant to another.

4.4 ▶ Oxidation–Reduction Reactions Examine reactions in which electrons are transferred from one reactant to another.

4.5 ▶ Concentrations of Solutions Learn to express the amount of a compound dissolved in a given volume of a solution as a *concentration* in the unit called *molarity*: moles of compound per liter of solution.

4.6 ▶ Solution Stoichiometry and Chemical Analysis Use the concepts of stoichiometry and concentration to calculate quantities involved in the laboratory technique known as titration.

Water covers nearly two-thirds of our planet, and this simple substance has been the key to much of Earth's evolutionary history. Life almost certainly originated in water, and the need for water by all forms of life has helped determine diverse biological structures. Indeed, most of the mass of our bodies is water, and the chemical reactions responsible for life occur in water.

A solution in which water is the dissolving medium is called an **aqueous solution**. In this chapter we examine chemical reactions that take place in aqueous solutions. In addition, we extend the concepts of stoichiometry learned in Chapter 3 by considering how solution concentrations are expressed and used. Although the reactions we discuss in this chapter are relatively simple, they form the basis for understanding complex reaction cycles in biology, geology, and oceanography.

4.1 | General Properties of Aqueous Solutions

Learning Objectives

When you finish Section 4.1, you should be able to:

- Classify solutes as strong electrolytes, weak electrolytes, or nonelectrolytes in water.
- Describe how ionic compounds dissolve and are solvated in water.
- Relate strong and weak electrolyte behavior to chemical equilibria in solution.

A *solution* is a homogeneous mixture of two or more substances. (Section 1.2) The substance present in the greatest quantity is usually called the **solvent**, and the other substances are called **solutes**; they are said to be *dissolved in* the solvent. When a small amount of sodium chloride (NaCl) is dissolved in a large quantity of water, for example, water is the solvent and sodium chloride is the solute. The majority of the chemical reactions discussed in this book, as well as most of the reactions you will do in the laboratory, occur in aqueous solution.

Electrolytes and Nonelectrolytes

Most of us learn at a young age to keep electrical devices out of the bathtub so we don't shock ourselves. Although most of the water we encounter in daily life is electrically conducting, pure water is a very poor conductor of electricity. The conductivity of bathwater originates from the substances dissolved in the water, not from the water itself.

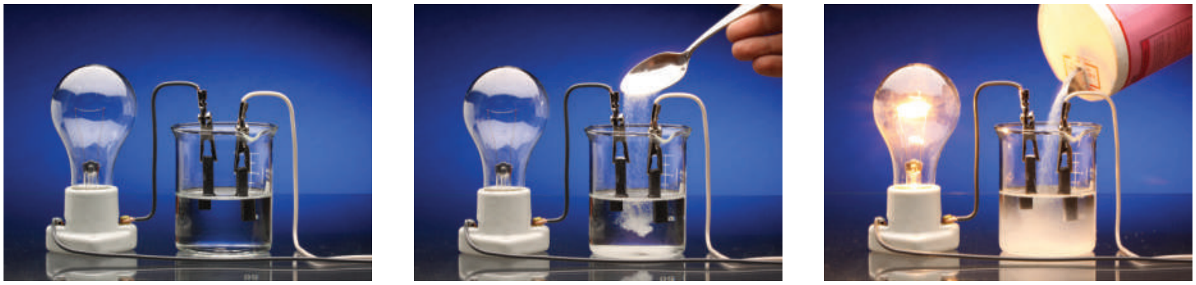
Not all substances that dissolve in water make the resulting solution conducting. **Figure 4.1** shows a simple experiment to test the electrical conductivity of three solutions: pure water, a solution of table sugar (sucrose) in water, and a solution of table salt (NaCl) in water. A light bulb is connected to a battery-powered electrical circuit that contains two electrodes submerged in a beaker of each solution. In order for the light bulb to turn on, there must be an electrical current (that is, a flow of electrically charged particles) between the two electrodes immersed in the solution. Because the light bulb does not turn on in pure water, we conclude that there are not enough charged particles in pure water to create a circuit; water must then mostly exist as H_2O molecules. The solution containing sucrose ($C_{12}H_{22}O_{11}$) also does not turn on the light bulb; therefore, we conclude that the sucrose molecules in solution are uncharged. But the solution containing NaCl does provide enough charged particles to create an electrical circuit and turn on the light bulb. This is experimental evidence that Na^+ and Cl^- ions are formed in aqueous solution.

A substance (such as NaCl) whose aqueous solutions contain ions is called an **electrolyte**. A substance (such as $C_{12}H_{22}O_{11}$) that does not form ions in solution is called a **nonelectrolyte**. The different classifications of NaCl and $C_{12}H_{22}O_{11}$ arise largely because NaCl is an ionic compound, whereas $C_{12}H_{22}O_{11}$ is a molecular compound.

Pure water does not conduct electricity.

A **nonelectrolyte solution** does not conduct electricity.

An **electrolyte solution** conducts electricity.



Pure water, $H_2O(l)$

Sucrose solution, $C_{12}H_{22}O_{11}(aq)$

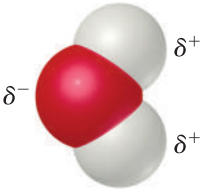
Sodium chloride solution, $NaCl(aq)$

▲ **Figure 4.1 Completion of an electrical circuit with an electrolyte turns on the light.**

How Compounds Dissolve in Water

Recall from Figure 2.19 that solid NaCl consists of an orderly arrangement of Na^+ and Cl^- ions. When NaCl dissolves in water, each ion separates from the solid structure and disperses throughout the solution [**Figure 4.2**(**a**)]. We say that the ionic solid *dissociates* into its component ions as it dissolves.

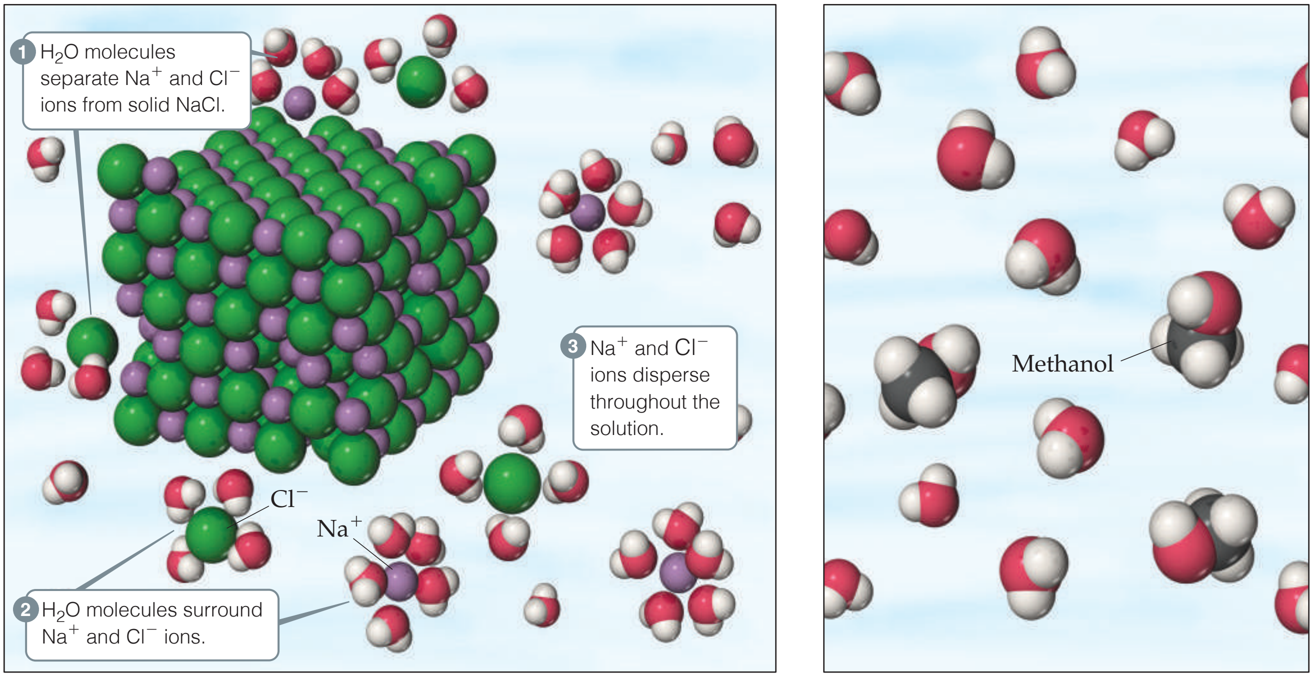
Water is a very effective solvent for ionic compounds. Although H_2O is an electrically neutral molecule, the O atom is rich in electrons and has a partial negative charge, while each H atom has a partial positive charge. The lowercase Greek letter delta (δ) is used to denote partial charge: A partial negative charge is denoted by δ^- ("delta minus"), and a partial positive charge is denoted by δ^+ ("delta plus"). Cations are attracted by the negative end of H_2O, whereas anions are attracted by the positive end.



As an ionic compound dissolves, the ions become surrounded by H_2O molecules, as shown in Figure 4.2(a). The ions are said to be *solvated*. In chemical equations, we denote solvated ions by writing them as $Na^+(aq)$ and $Cl^-(aq)$, where *aq* is an abbreviation for "aqueous." (Section 3.1) **Solvation** helps stabilize the ions in solution and prevents cations and anions from recombining. Furthermore, because the ions and their shells of surrounding water molecules are free to move about, the ions become dispersed uniformly throughout the solution.

We can usually predict the nature of the ions in a solution of an ionic compound from the chemical name of the substance. Sodium sulfate (Na_2SO_4), for example, dissociates into sodium ions (Na^+) and sulfate ions (SO_4^{2-}). You should learn the formulas and charges of common ions (Tables 2.4 and 2.5) to understand the forms in which ionic compounds exist in aqueous solution.

Go Figure Do both, just one, or neither of the solutions in this figure conduct electricity? If just one, which one?



① H_2O molecules separate Na^+ and Cl^- ions from solid NaCl.
③ Na^+ and Cl^- ions disperse throughout the solution.
Cl^-
Na^+
② H_2O molecules surround Na^+ and Cl^- ions.
Methanol

(a) Ionic compounds like sodium chloride, NaCl, form ions when they dissolve.

(b) Molecular substances like methanol, CH_3OH, dissolve without forming ions.

▲ **Figure 4.2 Dissolution in water.** (**a**) When an ionic compound, such as sodium chloride, NaCl, dissolves in water, H_2O molecules separate, surround, and uniformly disperse the ions into the liquid. (**b**) Molecular substances that dissolve in water, such as methanol, CH_3OH, usually do so without forming ions. We can think of methanol in water as a simple mixing of two molecular species. In both (a) and (b), the water molecules have been moved apart so that the solute particles can be seen clearly.

When a molecular compound such as sucrose or methanol [Figure 4.2(**b**)] dissolves in water, the solution usually consists of intact molecules dispersed throughout the solution. Consequently, most molecular compounds are nonelectrolytes. A few molecular substances do have aqueous solutions that contain ions. Acids are the most important of these solutions. For example, when $HCl(g)$ dissolves in water to form $HCl(aq)$, the molecule *ionizes*; that is, it dissociates into $H^+(aq)$ and $Cl^-(aq)$ ions.

Strong and Weak Electrolytes

Electrolytes differ in the extent to which they conduct electricity. **Strong electrolytes** are those solutes that exist in solution completely or nearly completely as ions. Essentially all water-soluble ionic compounds (such as NaCl) and a few molecular compounds (such as HCl) are strong electrolytes. **Weak electrolytes** are those solutes that exist in solution mostly in the form of neutral molecules with only a small fraction in the form of ions. For example, in a solution of acetic acid (CH_3COOH), most of the solute is present as $CH_3COOH(aq)$ molecules. Only a small fraction (about 1%) of the CH_3COOH has dissociated into $H^+(aq)$ and $CH_3COO^-(aq)$ ions.*

Do not confuse the extent to which an electrolyte dissolves (its solubility) with whether it is strong or weak. For example, CH_3COOH is extremely soluble in water but is a weak electrolyte. $Ca(OH)_2$, in contrast, is not very soluble in water, but the amount that does dissolve dissociates almost completely. Thus, $Ca(OH)_2$ is a strong electrolyte.

When a weak electrolyte, such as acetic acid, ionizes in solution, we write the reaction in the form

$$CH_3COOH(aq) \rightleftharpoons CH_3COO^-(aq) + H^+(aq) \qquad [4.1]$$

The half-arrows pointing in opposite directions mean that the reaction is significant in both directions. At any given moment, some CH_3COOH molecules are ionizing to form H^+ and CH_3COO^- ions, and some of the H^+ and CH_3COO^- ions are recombining to form CH_3COOH. The balance between these opposing processes determines the relative numbers of ions and neutral molecules. This balance produces a state of **chemical equilibrium** in which the relative numbers of each type of ion or molecule in the reaction are constant over time. Chemists use half-arrows pointing in opposite directions to represent reactions that go both forward and backward to achieve equilibrium, such as the ionization of weak electrolytes. In contrast, a single reaction arrow is used for reactions that largely go forward, such as the ionization of strong electrolytes. Because HCl is a strong electrolyte, we write the equation for the ionization of HCl as

$$HCl(aq) \longrightarrow H^+(aq) + Cl^-(aq) \qquad [4.2]$$

The absence of a left-pointing half-arrow indicates that the H^+ and Cl^- ions have no tendency to recombine to form HCl molecules.

In the following sections, we look at how a compound's composition lets us predict whether it is a strong electrolyte, a weak electrolyte, or a nonelectrolyte. For the moment, you need only to remember that *water-soluble ionic compounds are strong electrolytes*. Ionic compounds can usually be identified by the presence of both metals and nonmetals [for example, NaCl, $FeSO_4$, and $Al(NO_3)_3$]. Ionic compounds containing the ammonium ion, NH_4^+ [for example, NH_4Br and $(NH_4)_2CO_3$], are exceptions to this rule of thumb.

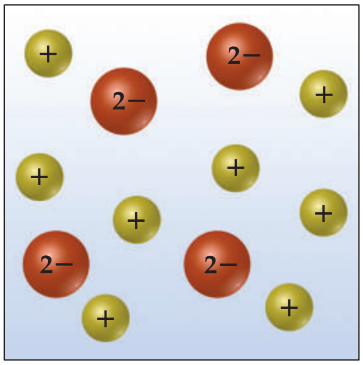
---

*The chemical formula of acetic acid is sometimes written $HC_2H_3O_2$, so that the formula looks like that of other common acids such as HCl. The formula CH_3COOH conforms to the molecular structure of acetic acid, with the acidic H on the O atom at the end of the formula.

Sample Exercise 4.1

Relating Relative Numbers of Anions and Cations to Chemical Formulas

The accompanying diagram represents an aqueous solution of either $MgCl_2$, KCl, or K_2SO_4. Which solution does the drawing best represent?



SOLUTION

Analyze We are asked to associate the charged spheres in the diagram with ions present in a solution of an ionic substance.

Plan We examine each ionic substance given to determine the relative numbers and charges of its ions. We then correlate these ionic species with the ones shown in the diagram.

Solve The diagram shows twice as many cations as anions, consistent with the formulation K_2SO_4.

Check Notice that the net charge in the diagram is zero, as it must be if it is to represent an ionic substance.

Practice Exercise

If you were to draw diagrams representing aqueous solutions of **(a)** $NiSO_4$, **(b)** $Ca(NO_3)_2$, **(c)** Na_3PO_4, **(d)** $Al_2(SO_4)_3$, how many anions would you show if each diagram contained six cations?

Self-Assessment Exercises

SAE 4.1 Which solution would contain 3 moles of ions for every mole of compound dissolved in water? **(a)** CH_3OH **(b)** NaCl **(c)** K_2SO_4 **(d)** $NaNO_3$ **(e)** $FeCl_3$

SAE 4.2 Consider the preparation of an aqueous solution of KBr from solid KBr and water. Which of the following statements is or are true?

- **(i)** Because KBr is a strong electrolyte, the chemical equilibrium reaction would show a one-way arrow from solid to ions.
- **(ii)** Once the solid is dissolved, the potassium ions are surrounded by water molecules, with the oxygen end of the H_2O molecule pointing at potassium.
- **(iii)** This solution would not conduct electricity.

(a) i only **(b)** ii only **(c)** iii only **(d)** i and ii **(e)** i, ii, and iii

SAE 4.3 Are compounds that are very water-soluble always strong electrolytes? Choose the correct combination of statements:

- **(i)** Yes, because a strong electrolyte is by definition very water-soluble.
- **(ii)** Yes, because all compounds that dissolve completely in water are ionic compounds.
- **(iii)** No, there are insoluble ionic compounds that are strong electrolytes.

(a) i only **(b)** ii only **(c)** iii only **(d)** both i and ii **(e)** None of i, ii, or iii is correct.

4.2 | Precipitation Reactions

Figure 4.3 shows two clear solutions being mixed. One solution contains potassium iodide, KI, dissolved in water, whereas the other contains lead nitrate, $Pb(NO_3)_2$, dissolved in water. The reaction between these two solutes produces a water-insoluble yellow solid. Reactions that result in the formation of an insoluble product are called **precipitation reactions**. A **precipitate** is an insoluble solid formed by a reaction in solution. In Figure 4.3 the precipitate is lead iodide (PbI_2), a compound that has a very low solubility in water (and so its phase is a solid, indicated by "*s*"):

$$Pb(NO_3)_2(aq) + 2\,KI(aq) \longrightarrow PbI_2(s) + 2\,KNO_3(aq) \qquad [4.3]$$

The other product of this reaction, potassium nitrate (KNO_3), remains in aqueous solution, so its phase is denoted as "*aq*."

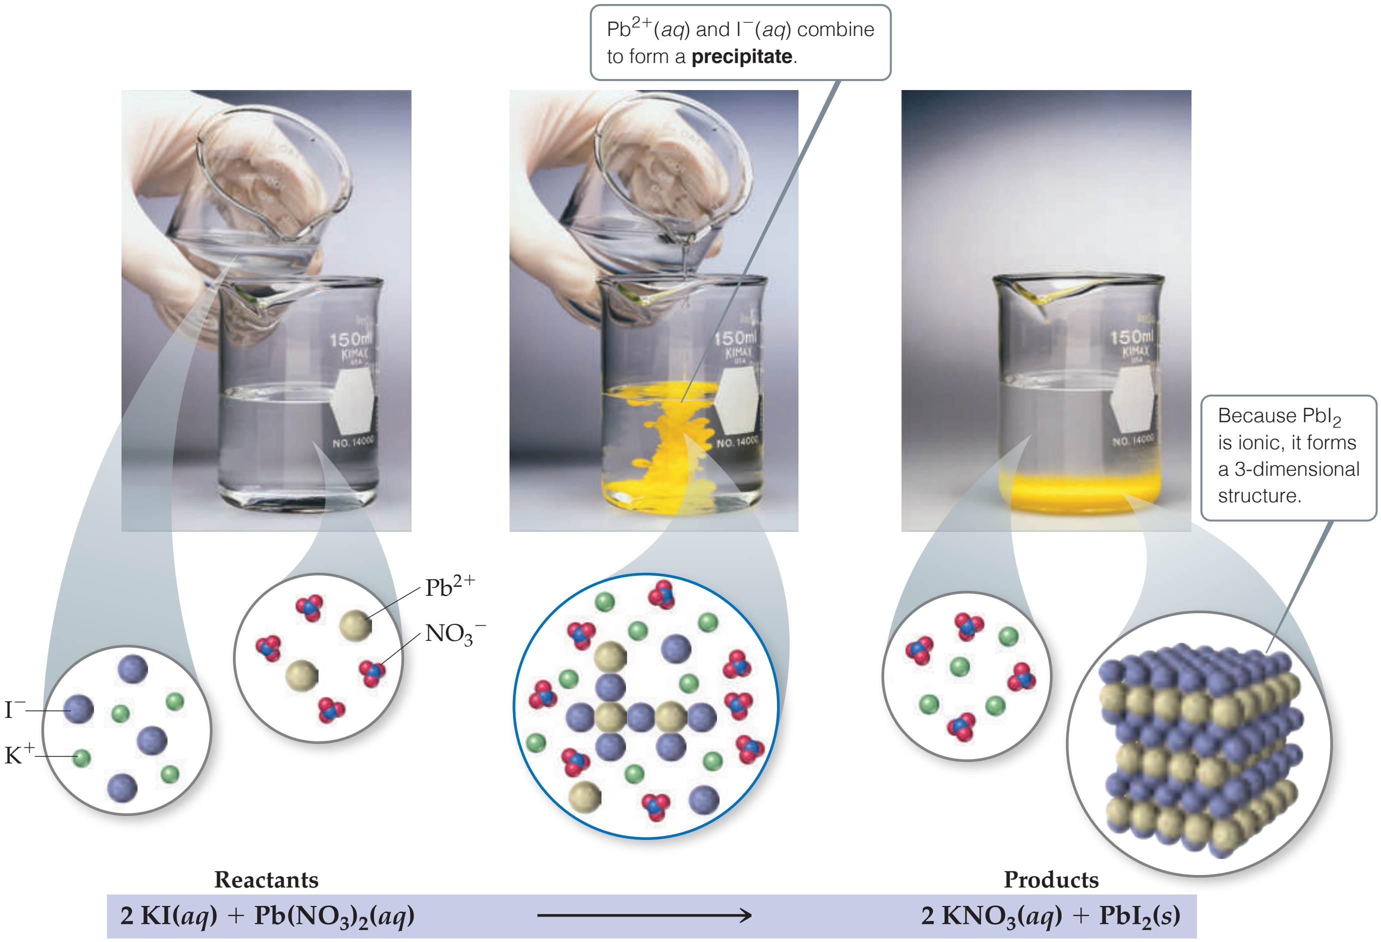
Precipitation reactions occur when pairs of oppositely charged ions attract each other so strongly that they form an insoluble ionic solid. To predict whether certain combinations of ions form insoluble compounds, we must consider some guidelines concerning the solubilities of common ionic compounds.

Learning Objectives

When you finish Section 4.2, you should be able to:

- Predict whether a compound is soluble or insoluble in water.
- Predict whether a precipitation reaction will occur when two aqueous solutions are mixed.
- Write balanced chemical equations including phases for metathesis reactions.
- Convert balanced molecular equations into full and net ionic equations.

Go Figure Which ions remain in solution after the PbI_2 precipitation is complete?



$Pb^{2+}(aq)$ and $I^-(aq)$ combine to form a **precipitate**.

Because PbI_2 is ionic, it forms a 3-dimensional structure.

Reactants
Products
$2\,KI(aq) + Pb(NO_3)_2(aq) \longrightarrow 2\,KNO_3(aq) + PbI_2(s)$

▲ **Figure 4.3** **A precipitation reaction.**

Solubility Guidelines for Ionic Compounds

The **solubility** of a substance at a given temperature is the amount of the substance that can be dissolved in a given quantity of solvent at the given temperature. Any substance with a solubility less than 0.01 mol/L will be considered *insoluble*. In these cases, the attraction between the oppositely charged ions in the solid is too great for the water molecules to separate the ions to any significant extent; the substance remains largely undissolved.

Unfortunately, there are no rules based on simple physical properties such as ionic charge to guide us in predicting whether a particular ionic compound will be soluble. Experimental observations, however, have led to guidelines for predicting solubility for ionic compounds. For example, experiments show that all common ionic compounds that contain the nitrate anion, NO_3^-, are soluble in water. **Table 4.1** summarizes the solubility guidelines for common ionic compounds. The table is organized according to the anion in the compound, but it also reveals many important facts about cations. Note that *all common ionic compounds of the alkali metal ions (group 1A of the periodic table) and of the ammonium ions* (NH_4^+) *are soluble in water*.

How to Predict Whether a Precipitate Forms When Strong Electrolytes Mix

1. Note the ions present in the reactants.
2. Consider the possible cation–anion combinations.
3. Use Table 4.1 to determine if any of the combinations is insoluble.

TABLE 4.1 Solubility Guidelines for Common Ionic Compounds in Water

Soluble Ionic Compounds		**Important Exceptions**
Compounds containing	NO_3^-	None
	CH_3COO^-	None
	Cl^-	Compounds of Ag^+, Hg_2^{2+}, and Pb^{2+}
	Br^-	Compounds of Ag^+, Hg_2^{2+}, and Pb^{2+}
	I^-	Compounds of Ag^+, Hg_2^{2+}, and Pb^{2+}
	SO_4^{2-}	Compounds of Sr^{2+}, Ba^{2+}, Hg_2^{2+}, and Pb^{2+}

Insoluble Ionic Compounds		**Important Exceptions**
Compounds containing	S^{2-}	Compounds of NH_4^+, the alkali metal cations, Ca^{2+}, Sr^{2+}, and Ba^{2+}
	CO_3^{2-}	Compounds of NH_4^+, and the alkali metal cations
	PO_4^{3-}	Compounds of NH_4^+, and the alkali metal cations
	OH^-	Compounds of NH_4^+, the alkali metal cations, Ca^{2+}, Sr^{2+}, and Ba^{2+}

For example, will a precipitate form when solutions of $Mg(NO_3)_2$ and NaOH are mixed? Both substances are soluble ionic compounds and strong electrolytes. Mixing the solutions first produces a solution containing Mg^{2+}, NO_3^-, Na^+, and OH^- ions. Will either cation interact with either anion to form an insoluble compound? Knowing from Table 4.1 that $Mg(NO_3)_2$ and NaOH are both soluble in water, our only possibilities are Mg^{2+} with OH^- and Na^+ with NO_3^-. From Table 4.1 we see that hydroxides are generally insoluble. Because Mg^{2+} is not an exception, $Mg(OH)_2$ is insoluble and thus forms a precipitate. $NaNO_3$, however, is soluble, so Na^+ and NO_3^- remain in solution. The balanced equation for the precipitation reaction is

$$Mg(NO_3)_2(aq) + 2\,NaOH(aq) \longrightarrow Mg(OH)_2(s) + 2\,NaNO_3(aq) \qquad [4.4]$$

Exchange (Metathesis) Reactions

Notice in Equation 4.4 that the reactant cations exchange anions—Mg^{2+} ends up with OH^-, and Na^+ ends up with NO_3^-. The chemical formulas of the products are based on the charges of the ions—two OH^- ions are needed to give a neutral compound with Mg^{2+}, and one NO_3^- ion is needed to give a neutral compound with Na^+. (Section 2.7) *The equation can be balanced only after the chemical formulas of the products have been determined.*

Sample Exercise 4.2

Using Solubility Rules

Classify these ionic compounds as soluble or insoluble in water: (**a**) sodium carbonate, Na_2CO_3, (**b**) lead sulfate, $PbSO_4$.

SOLUTION

Analyze We are given the names and formulas of two ionic compounds and asked to predict whether they are soluble or insoluble in water.

Plan We can use Table 4.1 to answer the question. Thus, we need to focus on the anion in each compound because the table is organized by anions.

Solve

(**a**) According to Table 4.1, most carbonates are insoluble. But carbonates of the alkali metal cations (such as sodium ion) are an exception to this rule and are soluble. Thus, Na_2CO_3 is soluble in water.

(**b**) Table 4.1 indicates that although most sulfates are water soluble, the sulfate of Pb^{2+} is an exception. Thus, $PbSO_4$ is insoluble in water.

Practice Exercise

Classify the following compounds as soluble or insoluble in water: (**a**) cobalt(II) hydroxide, (**b**) barium nitrate, (**c**) ammonium phosphate.

Reactions in which cations and anions appear to exchange partners conform to the general equation

$$AX + BY \longrightarrow AY + BX \qquad [4.5]$$

Example: $AgNO_3(aq) + KCl(aq) \longrightarrow AgCl(s) + KNO_3(aq)$

Such reactions are called either **exchange reactions** or **metathesis reactions** (meh-TATH-eh-sis, Greek for "to transpose"). Precipitation reactions conform to this pattern, as do many neutralization reactions between acids and bases, as we show in Section 4.3.

How to Balance a Metathesis Reaction

1. Use the chemical formulas of the reactants to determine which ions are present.
2. Write the chemical formulas of the products by combining the cation from one reactant with the anion of the other, using the ionic charges to determine the subscripts in the chemical formulas.
3. Check the water solubilities of the products. For a precipitation reaction to occur, at least one product must be insoluble in water.
4. Balance the equation.

Sample Exercise 4.3

Predicting a Metathesis Reaction

(**a**) Predict the identity of the precipitate that forms when aqueous solutions of $BaCl_2$ and K_2SO_4 are mixed. (**b**) Write the balanced chemical equation for the reaction.

SOLUTION

Analyze We are given two ionic reactants and asked to predict the insoluble product that they form.

Plan We need to write the ions present in the reactants and exchange the anions between the two cations. Once we have written the chemical formulas for these products, we can use Table 4.1 to determine which is insoluble in water. Knowing the products also allows us to write the equation for the reaction.

Solve

(**a**) The reactants contain Ba^{2+}, Cl^-, K^+, and SO_4^{2-} ions. Exchanging the anions gives us $BaSO_4$ and KCl. According to Table 4.1, most compounds of SO_4^{2-} are soluble, but those of Ba^{2+} are not. Thus, $BaSO_4$ is insoluble and will precipitate from solution. KCl is soluble.

(**b**) From part (**a**) we know the chemical formulas of the products, $BaSO_4$ and KCl. The balanced equation is

$$BaCl_2(aq) + K_2SO_4(aq) \longrightarrow BaSO_4(s) + 2\,KCl(aq)$$

▶ Practice Exercise

(**a**) What compound precipitates when aqueous solutions of $Fe_2(SO_4)_3$ and LiOH are mixed? (**b**) Write a balanced equation for the reaction.

Ionic Equations and Spectator Ions

In writing equations for reactions in aqueous solution, it is often useful to indicate whether the dissolved substances are present predominantly as ions or as molecules. Let's reconsider the precipitation reaction between $Pb(NO_3)_2$ and 2 KI (Eq. 4.3):

$$Pb(NO_3)_2(aq) + 2\,KI(aq) \longrightarrow PbI_2(s) + 2\,KNO_3(aq)$$

An equation written in this fashion, showing the complete chemical formulas of reactants and products, is called a **molecular equation** because it shows chemical formulas without indicating ionic character. Because $Pb(NO_3)_2$, KI, and KNO_3 are all water-soluble ionic compounds and therefore strong electrolytes, we can write the equation in a form that indicates which species exist as ions in the solution:

$$Pb^{2+}(aq) + 2\,NO_3^-(aq) + 2\,K^+(aq) + 2\,I^-(aq) \longrightarrow PbI_2(s) + 2\,K^+(aq) + 2\,NO_3^-(aq) \qquad [4.6]$$

An equation written in this form, with all soluble strong electrolytes shown as ions, is called a **complete ionic equation**.

Notice that $K^+(aq)$ and $NO_3^-(aq)$ appear on both sides of Equation 4.6. Ions that appear in identical forms on both sides of a complete ionic equation, called **spectator ions**, play no direct role in the reaction. Spectator ions, like algebraic quantities, can be canceled on either side of the reaction arrow because they are not reacting with anything. Once we cancel the spectator ions, we are left with the **net ionic equation**, which is one that includes only the ions and molecules directly involved in the reaction:

$$Pb^{2+}(aq) + 2\,I^-(aq) \longrightarrow PbI_2(s) \qquad [4.7]$$

Because charge is conserved in reactions, the sum of the ionic charges must be the same on both sides of a balanced net ionic equation. In this case, the 2+ charge of the cation and the two 1− charges of the anions add to zero, the charge of the electrically neutral product. *If every ion in a complete ionic equation is a spectator, no reaction occurs*.

Net ionic equations illustrate the similarities between various reactions involving electrolytes. For example, Equation 4.7 expresses the essential feature of the precipitation reaction between any strong electrolyte containing $Pb^{2+}(aq)$ and any strong electrolyte containing $I^-(aq)$: The ions combine to form a precipitate of PbI_2. Thus, a net ionic equation demonstrates that more than one set of reactants can lead to the same net reaction. For example, aqueous solutions of KI and MgI_2 share many chemical similarities because both contain I^- ions. Either solution when mixed with a $Pb(NO_3)_2$ solution produces $PbI_2(s)$. The complete ionic equation, however, identifies the actual reactants that participate in a reaction.

How to Write a Net Ionic Equation

1. Write a balanced molecular equation for the reaction.
2. Rewrite the equation to show the ions that form in solution when each soluble strong electrolyte dissociates into its ions. *Only strong electrolytes dissolved in aqueous solution are written in ionic form*.
3. Identify and cancel spectator ions.

Sample Exercise 4.4

Writing a Net Ionic Equation

Write the net ionic equation for the precipitation reaction that occurs when aqueous solutions of calcium chloride and sodium carbonate are mixed.

SOLUTION

Analyze Our task is to write a net ionic equation for a precipitation reaction, given the names of the reactants present in solution.

Plan We write the chemical formulas of the reactants and products and then determine which product is insoluble. We then write and balance the molecular equation. Next, we write each soluble strong electrolyte as separated ions to obtain the complete ionic equation. Finally, we eliminate the spectator ions to obtain the net ionic equation.

Solve Calcium chloride is composed of calcium ions, Ca^{2+}, and chloride ions, Cl^-; hence, an aqueous solution of the substance is $CaCl_2(aq)$. Sodium carbonate is composed of Na^+ ions and CO_3^{2-} ions; hence, an aqueous solution of the compound is $Na_2CO_3(aq)$. In the molecular equations for precipitation reactions, the anions and cations appear to exchange partners. Thus, we put Ca^{2+} and CO_3^{2-} together to give $CaCO_3$ and Na^+ and Cl^- together to give NaCl. According to the solubility guidelines in Table 4.1, $CaCO_3$ is insoluble and NaCl is soluble. The balanced molecular equation is

$$CaCl_2(aq) + Na_2CO_3(aq) \longrightarrow CaCO_3(s) + 2\,NaCl(aq)$$

In a complete ionic equation, *only* dissolved strong electrolytes (such as soluble ionic compounds) are written as separate ions. As the (*aq*) designations remind us, $CaCl_2$, Na_2CO_3, and NaCl are all dissolved in the solution. Furthermore, they are all strong electrolytes. $CaCO_3$ is an ionic compound, but it is not soluble. We do not write the formula of any insoluble compound as its component ions. Thus, the complete ionic equation is

$$Ca^{2+}(aq) + 2\,Cl^-(aq) + 2\,Na^+(aq) + CO_3^{2-}(aq) \longrightarrow CaCO_3(s) + 2\,Na^+(aq) + 2\,Cl^-(aq)$$

The spectator ions are Na^+ and Cl^-. Canceling them gives the following net ionic equation:

$$Ca^{2+}(aq) + CO_3^{2-}(aq) \longrightarrow CaCO_3(s)$$

Check We can check our result by confirming that both the elements and the electric charge are balanced. Each side has one Ca, one C, and three O, and the net charge on each side equals 0.

Comment If none of the ions in an ionic equation is removed from solution or is changed in some way, all ions are spectator ions and a reaction does not occur.

▶ Practice Exercise

Write the net ionic equation for the precipitation reaction that occurs when aqueous solutions of silver nitrate and potassium phosphate are mixed.

Self-Assessment Exercises

SAE 4.4 How many of the following compounds are soluble in water: CH_3COOBa, $MgCO_3$, FeS, $Mg_3(PO_4)_2$? (**a**) 0 (**b**) 1 (**c**) 2 (**d**) 3 (**e**) 4

SAE 4.5 What precipitate, if any, forms when a solution of ammonium sulfide is mixed with a solution of barium chloride? (**a**) NH_4Cl (**b**) BaS (**c**) $(NH_4)_2S$ (**d**) $BaCl_2$ (**e**) No precipitate forms.

SAE 4.6 An aqueous solution containing 3 millimoles of calcium chloride is mixed with an aqueous solution containing 2 millimoles of sodium phosphate. How many millimoles of calcium phosphate precipitate? (**a**) 0 (**b**) 1 (**c**) 2 (**d**) 3 (**e**) 6

SAE 4.7 An aqueous solution containing 2 millimoles of lead nitrate is mixed with an aqueous solution containing 4 millimoles of potassium iodide. How many millimoles of spectator ions, both cations and anions, are present in solution when the reaction is complete? (**a**) 0 (**b**) 4 (**c**) 8 (**d**) 12 (**e**) 14

4.3 | Acids, Bases, and Neutralization Reactions

Learning Objectives

When you finish Section 4.3, you should be able to:

- Describe the defining features of compounds that act as either acids or bases.
- Predict whether a compound is an acid or a base based on its chemical formula/structure.
- Differentiate between strong and weak acids/bases.
- Classify compounds as either strong or weak electrolytes based on their acid–base behavior.
- Write balanced chemical equations for neutralization reactions.

Chemists routinely examine the chemical formula and structure of a compound and predict its reactivity. Acids, bases, and acid–base reactions are among the most common type of compounds and reactivity that chemists use to develop new pharmaceuticals, new plastics, and many other useful substances.

Many acids and bases are industrial and household substances (**Figure 4.4**), and some are important components of biological fluids. Hydrochloric acid, for example, is both an important industrial chemical and the main constituent of gastric juice in your stomach. Acids and bases are also common electrolytes. In this section we examine the simplest description of acids and bases, which involve the presence of H^+ and OH^- ions in aqueous solution.

▲ **Figure 4.4 Common household acids and bases.** Vinegar and lemon juice are common household acids. Ammonia and baking soda (sodium bicarbonate) are common household bases.

Acids

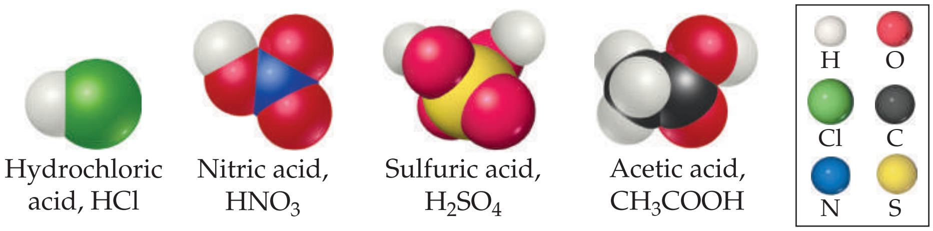
As noted in Section 2.8, **acids** are substances that ionize in aqueous solution to form hydrogen ions $H^+(aq)$. Because a hydrogen atom consists of a proton and an electron, H^+ is simply a proton. Thus, acids are often called *proton donors*. Molecular models of four common acids are shown in **Figure 4.5**.

Protons in aqueous solution are solvated by water molecules, just as other cations are [Figure 4.2(**a**)]. In writing chemical equations involving protons in water, therefore, we write $H^+(aq)$.

Molecules of different acids ionize to form different numbers of H^+ ions. Both HCl and HNO_3 are *monoprotic* acids, yielding one H^+ per molecule of acid. Sulfuric acid, H_2SO_4, is a *diprotic* acid, one that yields two H^+ per molecule of acid. The ionization of H_2SO_4 and other diprotic acids occurs in two steps:

$$H_2SO_4(aq) \longrightarrow H^+(aq) + HSO_4^-(aq) \qquad [4.8]$$

$$HSO_4^-(aq) \rightleftharpoons H^+(aq) + SO_4^{2-}(aq) \qquad [4.9]$$



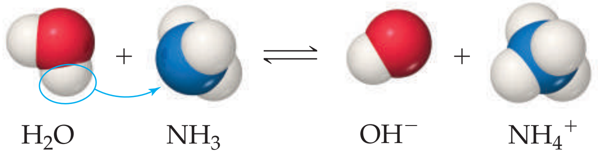
Hydrochloric acid, HCl

Nitric acid, HNO_3

Sulfuric acid, H_2SO_4

Acetic acid, CH_3COOH

▲ **Figure 4.5 Molecular models of four common acids.**



▲ **Figure 4.6** **Proton transfer.** An H_2O molecule acts as a proton donor (acid), and NH_3 acts as a proton acceptor (base). In aqueous solutions, only a fraction of the NH_3 molecules react with H_2O. Consequently, NH_3 is a weak electrolyte.

Although H_2SO_4 is a strong electrolyte, only the first ionization (Equation 4.8) is complete. Thus, aqueous solutions of sulfuric acid contain a mixture of $H^+(aq)$, $HSO_4^-(aq)$, and $SO_4^{2-}(aq)$.

The molecule CH_3COOH (acetic acid) that we have mentioned frequently is the primary component in vinegar. Acetic acid has four hydrogens, as Figure 4.5 shows, but only one of them, the H that is bonded to an oxygen in the —COOH group, is ionized in water. Thus, the H in the COOH group breaks its O—H bond in water. The three other hydrogens in acetic acid are attached to carbon and do not break their C—H bonds in water. The reasons for this difference are very interesting and are discussed in Chapter 16.

Bases

Bases are substances that accept (react with) H^+ ions. Bases produce hydroxide ions (OH^-) when they dissolve in water. Ionic hydroxide compounds, such as NaOH, KOH, and $Ca(OH)_2$, are among the most common bases. When dissolved in water, they dissociate into ions, introducing OH^- ions into the solution.

Compounds that do not contain OH^- ions can also be bases. For example, ammonia (NH_3) is a common base. When added to water, it accepts an H^+ ion from a water molecule and thereby produces an OH^- ion (**Figure 4.6**):

$$H_2O(l) + NH_3(aq) \rightleftharpoons OH^-(aq) + NH_4^+(aq) \qquad [4.10]$$

Ammonia is a weak electrolyte because only about 1% of the NH_3 forms NH_4^+ and OH^- ions.

Strong and Weak Acids and Bases

Acids and bases that are strong electrolytes (completely ionized in solution) are **strong acids** and **strong bases**. Those that are weak electrolytes (partly ionized) are **weak acids** and **weak bases**. When reactivity depends only on $H^+(aq)$ concentration, strong acids are more reactive than weak acids. The reactivity of an acid, however, can depend on the anion as well as on $H^+(aq)$ concentration. For example, hydrofluoric acid (HF) is a weak acid (only partly ionized in aqueous solution), but it is very reactive and vigorously attacks many substances, including glass. This reactivity is due to the combined action of $H^+(aq)$ and $F^-(aq)$.

Table 4.2 lists the strong acids and bases we are most likely to encounter. You should commit this information to memory in order to correctly identify strong electrolytes and write net ionic equations. The list is brief because most acids are weak. (For H_2SO_4, as we noted earlier, only the first proton completely ionizes.) The only common strong bases

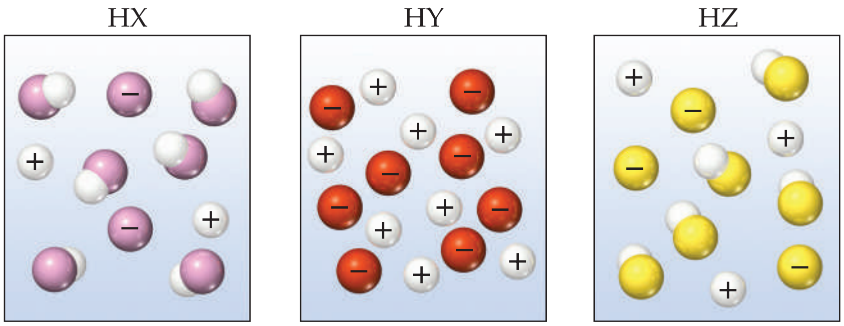
TABLE 4.2 Common Strong Acids and Bases

Strong Acids	Strong Bases
Hydrochloric acid, HCl	Group 1A metal hydroxides (LiOH, NaOH, KOH, RbOH, CsOH)
Hydrobromic acid, HBr	
Hydroiodic acid, HI	Heavy group 2A metal hydroxides $[Ca(OH)_2, Sr(OH)_2, Ba(OH)_2]$
Chloric acid, $HClO_3$	
Perchloric acid, $HClO_4$	
Nitric acid, HNO_3	
Sulfuric acid (first proton), H_2SO_4	

Sample Exercise 4.5

Comparing Acid Strengths

The following diagrams represent aqueous solutions of acids HX, HY, and HZ, with water molecules omitted for clarity. Rank the acids from strongest to weakest.



SOLUTION

Analyze We are asked to rank three acids from strongest to weakest, based on schematic drawings of their solutions.

Plan We can determine the relative numbers of uncharged molecular species in the diagrams. The strongest acid is the one with the most H^+ ions and the fewest undissociated molecules in solution. The weakest acid is the one with the largest number of undissociated molecules.

Solve The order is $HY > HZ > HX$. HY is a strong acid because it is totally ionized (no HY molecules in solution), whereas both HX and HZ are weak acids, whose solutions consist of a mixture of molecules and ions. Because HZ contains more H^+ ions and fewer molecules than HX, it is a stronger acid.

Practice Exercise

When a substance HA is dissolved in water, the concentration of HA(*aq*) is much greater than the concentrations of $H^+(aq)$ and $A^-(aq)$. Is HA a strong acid, a strong base, a weak acid, or a weak base? What reasoning led to your decision?

are the common soluble metal hydroxides. The most common weak base is NH_3, which reacts with water to form OH^- ions (Equation 4.10).

If our substance is a base, we can use Table 4.2 to determine whether it is a strong base. NH_3 is the only molecular base that we consider in this chapter, and it is a weak base; it is therefore a weak electrolyte (see **Table 4.3**). Finally, any molecular substance that we encounter in this chapter that is not an acid or NH_3 is probably a nonelectrolyte.

Identifying Strong and Weak Electrolytes

If we remember the common strong acids and bases (Table 4.2) and also remember that NH_3 is a weak base, we can make reasonable predictions about the electrolytic strength of a great number of *water-soluble* substances. Table 4.3 summarizes our observations about electrolytes. We first ask whether the substance is ionic or molecular. If it is ionic, it is a strong electrolyte. If the substance is molecular, we ask whether it is an acid or a base. (It is an acid if it either has H first in the chemical formula or contains a COOH group.) If it is an acid, we use Table 4.2 to determine whether it is a strong or weak electrolyte: All strong acids are strong electrolytes, and all weak acids are weak electrolytes. If an acid is not listed in Table 4.2, it is probably a weak acid and therefore a weak electrolyte.

TABLE 4.3 Summary of the Electrolytic Behavior of Common Soluble Ionic and Molecular Compounds

	Strong Electrolyte	Weak Electrolyte	Nonelectrolyte
Ionic	All	None	None
Molecular	Strong acids (see Table 4.2)	Weak acids, weak bases	All other compounds

Sample Exercise 4.6

Identifying Strong, Weak, and Nonelectrolytes

Classify these dissolved substances as a strong electrolyte, weak electrolyte, or nonelectrolyte: $CaCl_2$, HNO_3, C_2H_5OH (ethanol), HCOOH (formic acid), KOH.

SOLUTION

Analyze We are given several chemical formulas and asked to classify each substance as a strong electrolyte, weak electrolyte, or nonelectrolyte.

Plan The approach we take is outlined in Table 4.3. We can predict whether a substance is ionic or molecular based on its composition. As we saw in Section 2.7, most ionic compounds we encounter in this text are composed of a metal and a nonmetal, whereas most molecular compounds are composed only of nonmetals.

Solve Two compounds fit the criteria for ionic compounds: $CaCl_2$ and KOH. According to Table 4.3, all ionic compounds are strong electrolytes, so that is how we classify these two substances. The three remaining compounds are molecular. Two of these molecular substances, HNO_3 and HCOOH, are acids. Nitric acid, HNO_3, is a common strong acid (see Table 4.2), so it is a strong electrolyte. Because most acids are weak acids, our best guess would be that HCOOH is a weak acid (weak electrolyte), which is in fact the case. The remaining molecular compound, C_2H_5OH, is neither an acid nor a base, so it is a nonelectrolyte.

Comment Although ethanol, C_2H_5OH, has an OH group, it is not a metal hydroxide and therefore not a base. Rather, ethanol is a member of a class of organic compounds that have $C—OH$ bonds, which are known as alcohols. (Section 2.9) Organic compounds containing the COOH group are called carboxylic acids (Chapter 16). Molecules that have this group are weak acids.

Practice Exercise

Consider solutions in which 0.1 mol of each of the following compounds is dissolved in 1 L of water: $Ca(NO_3)_2$ (calcium nitrate), $C_6H_{12}O_6$ (glucose), $NaCH_3COO$ (sodium acetate), and CH_3COOH (acetic acid). Rank the solutions in order of increasing electrical conductivity. (Note: The conductivity increases as the number of ions in solution increases.)

Neutralization Reactions and Salts

The properties of acidic solutions are quite different from those of basic solutions. Acids have a sour taste, whereas bases have a bitter taste.* Acids change the colors of certain dyes in a way that differs from the way bases affect the same dyes. This is the principle behind the indicator known as litmus paper (**Figure 4.7**). Acid–base chemistry is an important theme throughout all of chemistry that we begin to explore here.

When a solution of an acid and a solution of a base are mixed, a **neutralization reaction** occurs. The products of the reaction have none of the characteristic properties of either the acidic solution or the basic solution. For example, when hydrochloric acid is mixed with a solution of sodium hydroxide, the reaction is

$$\underset{\text{(acid)}}{HCl(aq)} + \underset{\text{(base)}}{NaOH(aq)} \longrightarrow \underset{\text{(water)}}{H_2O(l)} + \underset{\text{(salt)}}{NaCl(aq)} \qquad [4.11]$$

Water and table salt, NaCl, are the products of the reaction. By analogy to this reaction, the term **salt** has come to mean any ionic compound whose cation comes from a base (for example, Na^+ from NaOH) and whose anion comes from an acid (for example, Cl^- from HCl). In general, *a neutralization reaction between an acid and a metal hydroxide produces water and a salt.*

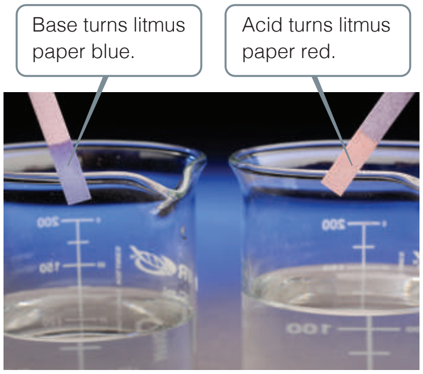
Because HCl, NaOH, and NaCl are all water-soluble strong electrolytes, the complete ionic equation associated with Equation 4.11 is

$$H^+(aq) + Cl^-(aq) + Na^+(aq) + OH^-(aq) \longrightarrow H_2O(l) + Na^+(aq) + Cl^-(aq) \qquad [4.12]$$

Therefore, the net ionic equation is

$$H^+(aq) + OH^-(aq) \longrightarrow H_2O(l) \qquad [4.13]$$

Equation 4.13 summarizes the main feature of the neutralization reaction between any strong acid and any strong base: $H^+(aq)$ and $OH^-(aq)$ ions combine to form $H_2O(l)$.



▲ **Figure 4.7 Litmus paper.** Litmus paper is coated with dyes that change color in response to exposure to either acids or bases.

---

*Tasting chemical solutions is not a good practice. However, we have all had acids such as ascorbic acid (vitamin C), acetylsalicylic acid (aspirin), and citric acid (in citrus fruits) in our mouths, and we are familiar with their characteristic sour taste. Soaps, which are basic, have the characteristic bitter taste of bases.

Figure 4.8 shows the neutralization reaction between hydrochloric acid and the water-insoluble base $Mg(OH)_2$:

Molecular equation:

$$\mathrm{Mg(OH)_2}(s) + 2\,\mathrm{HCl}(aq) \longrightarrow \mathrm{MgCl_2}(aq) + 2\,\mathrm{H_2O}(l) \qquad [4.14]$$

Net ionic equation:

$$\mathrm{Mg(OH)_2}(s) + 2\,\mathrm{H^+}(aq) \longrightarrow \mathrm{Mg^{2+}}(aq) + 2\,\mathrm{H_2O}(l) \qquad [4.15]$$

Notice that the OH^- ions (this time in a solid reactant) and H^+ ions combine to form H_2O. Because the ions exchange partners, neutralization reactions between acids and metal hydroxides are metathesis reactions.

Sample Exercise 4.7

Writing Chemical Equations for a Neutralization Reaction

For the reaction between aqueous solutions of acetic acid (CH_3COOH) and barium hydroxide, $Ba(OH)_2$, write (**a**) the balanced molecular equation, (**b**) the complete ionic equation, and (**c**) the net ionic equation.

SOLUTION

Analyze We are given the chemical formulas for an acid and a base and are asked to write a balanced molecular equation, a complete ionic equation, and a net ionic equation for their neutralization reaction.

Plan As Equation 4.11 and the italicized statement that follows it indicate, neutralization reactions form two products, H_2O and a salt. We examine the cation of the base and the anion of the acid to determine the composition of the salt.

Solve

(**a**) The salt contains the cation of the base (Ba^{2+}) and the anion of the acid (CH_3COO^-). Thus, the salt formula is $Ba(CH_3COO)_2$. According to Table 4.1, this compound is soluble in water. The unbalanced molecular equation for the neutralization reaction is

$$\mathrm{CH_3COOH}(aq) + \mathrm{Ba(OH)_2}(aq) \longrightarrow \mathrm{H_2O}(l) + \mathrm{Ba(CH_3COO)_2}(aq)$$

To balance this equation, we must provide two molecules of CH_3COOH to furnish the two CH_3COO^- ions and to supply the two H^+ ions needed to combine with the two OH^- ions of the base. The balanced molecular equation is

$$2\,\mathrm{CH_3COOH}(aq) + \mathrm{Ba(OH)_2}(aq) \longrightarrow 2\,\mathrm{H_2O}(l) + \mathrm{Ba(CH_3COO)_2}(aq)$$

(**b**) To write the complete ionic equation, we identify the strong electrolytes and break them into ions. In this case, $Ba(OH)_2$ and $Ba(CH_3COO)_2$ are both water-soluble ionic compounds and hence strong electrolytes. Thus, the complete ionic equation is

$$2\,\mathrm{CH_3COOH}(aq) + \mathrm{Ba^{2+}}(aq) + 2\mathrm{OH^-}(aq) \longrightarrow 2\,\mathrm{H_2O}(l) + \mathrm{Ba^{2+}}(aq) + 2\,\mathrm{CH_3COO^-}(aq)$$

(**c**) Eliminating the spectator ion, Ba^{2+}, and simplifying coefficients give the net ionic equation:

$$\mathrm{CH_3COOH}(aq) + \mathrm{OH^-}(aq) \longrightarrow \mathrm{H_2O}(l) + \mathrm{CH_3COO^-}(aq)$$

Check We can determine whether the molecular equation is balanced by counting the number of atoms of each kind on both sides of the arrow (10 H, 6 O, 4 C, and 1 Ba on each side). However, it is often easier to check equations by counting groups: There are 2 CH_3COO groups, as well as 1 Ba, and 4 additional H atoms and 2 additional O atoms on each side of the equation. The net ionic equation checks out because the numbers of each kind of element and the net charge are the same on both sides of the equation.

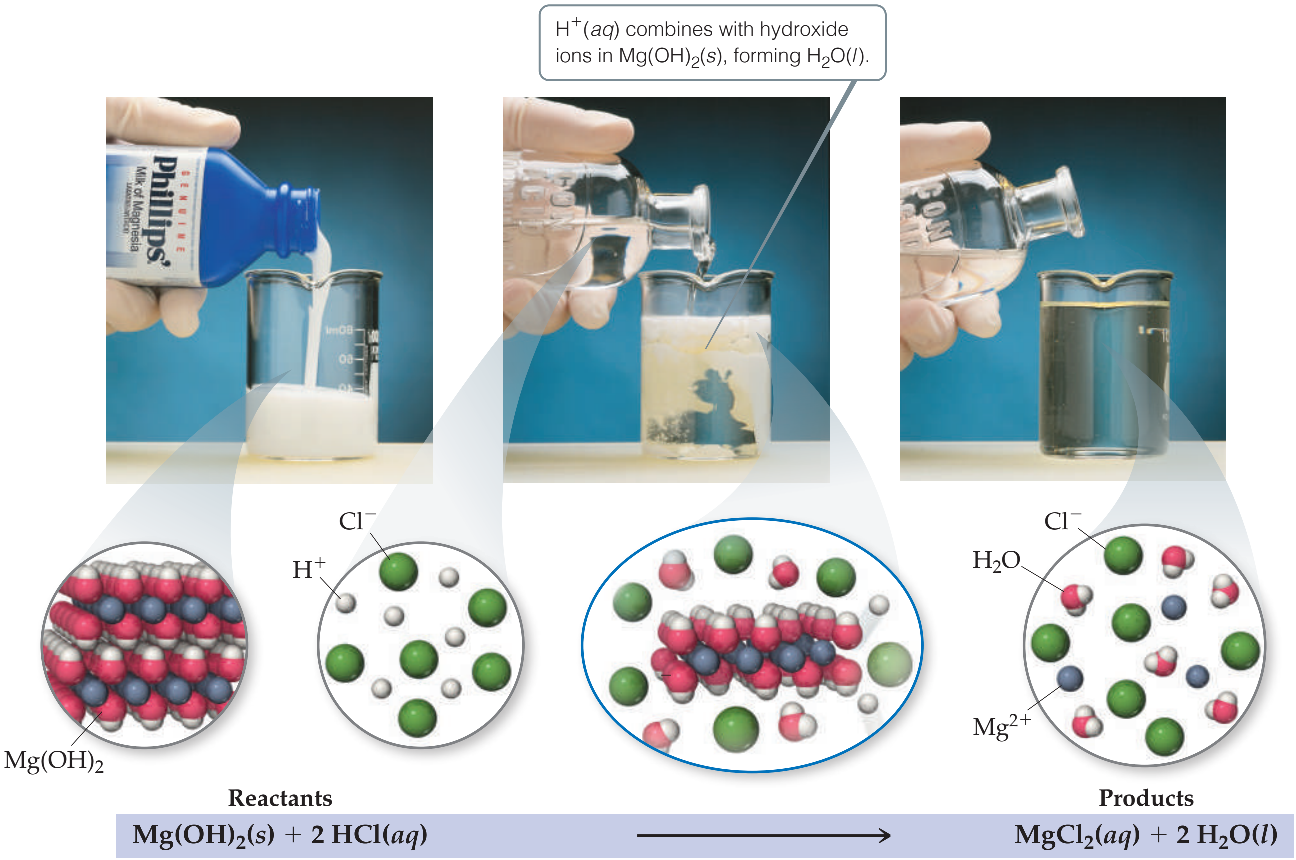
▶ Practice Exercise

For the reaction of aqueous potassium hydroxide with sulfuric acid, write (**a**) the balanced molecular equation and (**b**) the net ionic equation, assuming that both protons of sulfuric acid react.

Neutralization Reactions with Gas Formation

Many bases besides OH^- react with H^+ to form molecular compounds. Two of these that you might encounter in the laboratory are the sulfide ion and the carbonate ion. Both of these anions react with acids to form gases that have low solubilities in water.

Go Figure If you used nitric acid instead of hydrochloric acid in this reaction, what products would form?



$$Mg(OH)_2(s) + 2\,HCl(aq) \longrightarrow MgCl_2(aq) + 2\,H_2O(l)$$

▲ **Figure 4.8 Neutralization reaction between $Mg(OH)_2(s)$ and hydrochloric acid.** Milk of magnesia is a suspension of water-insoluble magnesium hydroxide, $Mg(OH)_2(s)$, in water. When sufficient hydrochloric acid, $HCl(aq)$, is added, a reaction ensues that leads to an aqueous solution containing $Mg^{2+}(aq)$ and $Cl^-(aq)$ ions.

Hydrogen sulfide (H_2S), the substance that gives rotten eggs their foul odor, forms when an acid such as $HCl(aq)$ reacts with a metal sulfide such as Na_2S:

Molecular equation:

$$2\,HCl(aq) + Na_2S(aq) \longrightarrow H_2S(g) + 2\,NaCl(aq) \qquad [4.16]$$

Net ionic equation:

$$2\,H^+(aq) + S^{2-}(aq) \longrightarrow H_2S(g) \qquad [4.17]$$

Carbonates and bicarbonates react with acids to form $CO_2(g)$. Reaction of CO_3^{2-} or HCO_3^- with an acid first gives carbonic acid (H_2CO_3). For example, when hydrochloric acid is added to sodium bicarbonate, the reaction is

$$HCl(aq) + NaHCO_3(aq) \longrightarrow NaCl(aq) + H_2CO_3(aq) \qquad [4.18]$$

Carbonic acid is unstable. If present in solution in sufficient concentrations, it decomposes to H_2O and CO_2,. The CO_2 then escapes from the solution as a gas:

$$H_2CO_3(aq) \longrightarrow H_2O(l) + CO_2(g) \qquad [4.19]$$

The overall reaction is summarized by the following equations:

Molecular equation:

$$HCl(aq) + NaHCO_3(aq) \longrightarrow NaCl(aq) + H_2O(l) + CO_2(g) \qquad [4.20]$$

Net ionic equation:

$$H^+(aq) + HCO_3^-(aq) \longrightarrow H_2O(l) + CO_2(g) \qquad [4.21]$$

Both $NaHCO_3(s)$ and $Na_2CO_3(s)$ are used as neutralizers in acid spills; either salt is added until the fizzing caused by $CO_2(g)$ formation stops. Sometimes sodium bicarbonate is used as an antacid to soothe an upset stomach. In that case the HCO_3^- reacts with stomach acid to form $CO_2(g)$.

CHEMISTRY AND LIFE Stomach Acids and Antacids

Your stomach secretes acids to help digest foods. These acids, which include hydrochloric acid, contain about 0.1 mol of H^+ per liter of solution. The stomach and digestive tract are normally protected from the corrosive effects of stomach acid by a mucosal lining. Holes can develop in this lining, however, allowing the acid to attack the underlying tissue, causing painful damage. These holes, known as ulcers, can be caused by the secretion of excess acids and/or by a weakness in the digestive lining. Many peptic ulcers are caused by infection by the bacterium *Helicobacter pylori*. Between 10 and 20% of Americans suffer from ulcers at some point in their lives. Many others experience occasional indigestion, heartburn, or reflux due to digestive acids entering the esophagus.

The problem of excess stomach acid can be addressed by (1) removing the excess acid or (2) decreasing the production of acid. Substances that remove excess acid are called *antacids*, whereas those that decrease acid production are called *acid inhibitors*. **Figure 4.9** shows several common over-the-counter antacids, which usually contain hydroxide, carbonate, or bicarbonate ions (**Table 4.4**). Antiulcer drugs, such as Tagamet® and Zantac®, are acid inhibitors. They act on acid-producing cells in the lining of the stomach. Formulations that control acid in this way are now available as over-the-counter drugs.

Self-Assessment Exercises

SAE 4.8 How many of the following compounds are a weak acid: sulfuric acid, ammonia, nitric acid, acetic acid? (**a**) 0 (**b**) 1 (**c**) 2 (**d**) 3 (**e**) 4

SAE 4.9 Which statement about bases is *true*? (**a**) All bases produce hydroxide ions in water. (**b**) Ammonia is an example of a strong base. (**c**) Cesium hydroxide is not a base because it is not soluble in water. (**d**) Bases donate protons to water.

SAE 4.10 If you want to neutralize an aqueous solution of HCl with the smallest number of moles of reagent possible, what reagent is the best choice? (**a**) HNO_3 (**b**) NaOH (**c**) $Ca(OH)_2$ (**d**) Na_3PO_4 (**e**) NH_3

SAE 4.11 Which statement about neutralization reactions is *false*? (**a**) Neutralization reactions can be summarized as "acid plus base produces a salt plus water." (**b**) Neutralization reactions always require one mole of the acid for every mole of the base. (**c**) Neutralization reactions can produce gases as products. (**d**) If your base is a solid, dripping a solution of acid on it will still produce a reaction.

SAE 4.12 What is the balanced net ionic equation for the neutralization reaction between acetic acid, CH_3COOH, and strontium hydroxide?

(**a**) $2CH_3COOH(aq) + Sr(OH)_2(aq) \longrightarrow (CH_3COO)_2Sr(aq) + 2H_2O(l)$

(**b**) $2CH_3COOH(aq) + Sr^{2+}(aq) + 2OH^-(aq) \longrightarrow 2CH_3COO^-(aq) + Sr^{2+}(aq) + 2H_2O(l)$

(**c**) $H^+(aq) + OH^-(aq) \longrightarrow H_2O(l)$

(**d**) $2H^+(aq) + 2OH^-(aq) \longrightarrow 2H_2O(l)$

(**e**) $CH_3COOH(aq) + OH^-(aq) \longrightarrow CH_3COO^-(aq) + H_2O(l)$

CHEMISTRY AND SUSTAINABILITY Acid Rain

Raindrops are slightly acidic, due to dissolved carbon dioxide from the atmosphere:

$$CO_2(g) + H_2O(l) \longrightarrow H_2CO_3(aq)$$

This reaction is the reverse of Equation 4.19, and it occurs because a chemical equilibrium exists between carbonic acid and carbon dioxide in the raindrop.

The burning of coal and other fossil fuels produces CO_2 as well as various sulfur oxides (due to sulfur-containing impurities in the fossil fuels). One of these sulfur-containing compounds is SO_2, which can undergo further reaction to produce SO_3. SO_3 then reacts with water to produce the strong acid sulfuric acid:

$$SO_3(g) + H_2O(l) \longrightarrow H_2SO_4(aq)$$

Similarly, nitrogen oxides (NO, NO_2) that are by-products from fossil fuel combustion can react with water to produce nitric acid, HNO_3, another strong acid. Both sulfuric acid and nitric acid produced this way contribute to **acid rain**, rain that is 10 times more acidic than nature's rain. For many years, acid rain in some parts of the world caused buildings, plants, animals, and soil to suffer many adverse effects. But as scientists have figured out how to clean up the emissions as well as move to other sources of energy, acid rain is becoming less of a problem. We discuss acid rain in more detail in Chapter 18.

4.4 Oxidation–Reduction Reactions

In precipitation reactions, cations and anions come together to form an insoluble ionic compound. In neutralization reactions, protons are transferred from one reactant to another. Now let's consider a third kind of reaction, one in which electrons are transferred from one reactant to another. Such reactions are called either **oxidation–reduction reactions** or **redox reactions**. In this section we concentrate on redox reactions where one of the reactants is a metal in its elemental form. Redox reactions are critical in understanding many biological and geological processes in the world around us; they also form the basis for energy-related technologies such as batteries and fuel cells (Chapter 20).

Learning Objectives

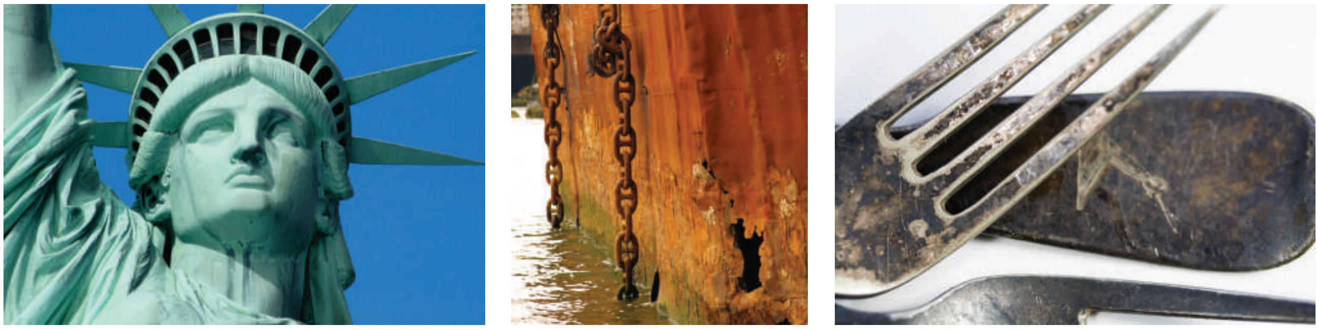
When you finish Section 4.4, you should be able to:

- Determine the oxidation numbers (also called oxidation states) of elements in a compound.
- Identify which species are oxidized and which are reduced in an oxidation–reduction reaction.
- Write balanced chemical equations for oxidation–reduction reactions.
- Use the activity series to predict oxidation–reduction reactions between a metal and a metal cation or an acid (displacement reactions).

Oxidation and Reduction

One of the most familiar redox reactions is *corrosion* of a metal (**Figure 4.10**). In some instances, corrosion is limited to the surface of the metal, as is the case with the green coating that forms on copper roofs and statues. In other instances, the corrosion goes deeper, eventually compromising the structural integrity of the metal, as happens with the rusting of iron.

Corrosion is the conversion of a metal into a metal compound, by a reaction between the metal and some substance in its environment. When a metal corrodes, each metal atom loses one or more electrons to form a cation, which can combine with an anion to form an ionic compound. The green coating on the Statue of Liberty contains Cu^{2+} combined with carbonate and hydroxide anions; rust contains Fe^{3+} combined with oxide and hydroxide anions; and silver tarnish contains Ag^{+} combined with sulfide anions.



(a) (b) (c)

▲ **Figure 4.10** **Familiar corrosion products.** (**a**) A green coating forms when copper is oxidized. (**b**) Rust forms when iron corrodes. (**c**) A black tarnish forms as silver corrodes.

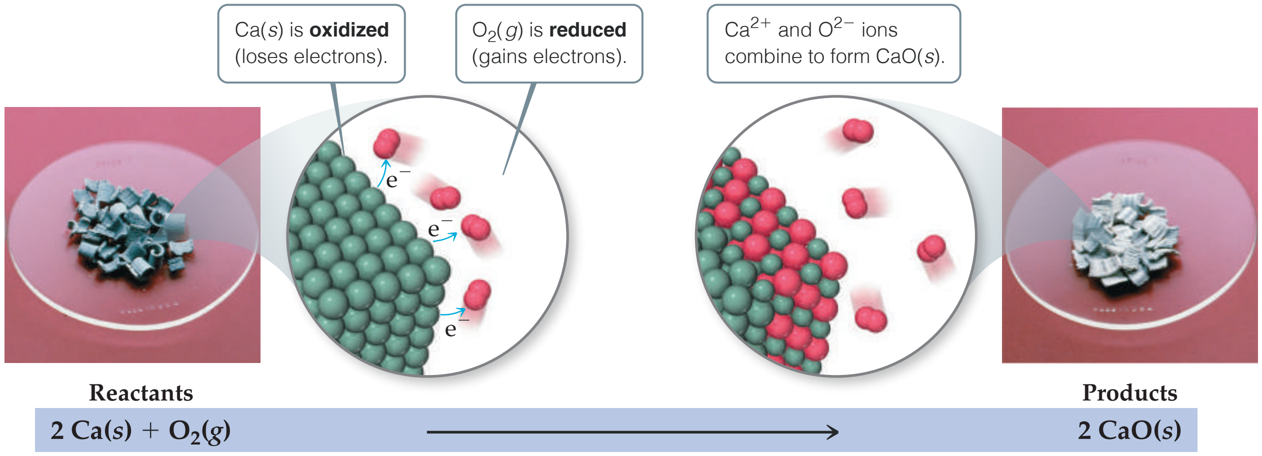
When an atom, ion, or molecule becomes more positively charged (that is, when it loses electrons), we say that it has been *oxidized*. Loss of electrons by a substance is called **oxidation**. The term *oxidation* is used because the first reactions of this sort to be studied were reactions with oxygen. Many metals react directly with O_2 in air to form metal oxides. In these reactions, the metal loses electrons to oxygen, forming an ionic compound of the metal ion and oxide ion. Rusting involves the reaction between iron metal and oxygen in the presence of water. In this process, Fe is *oxidized* (loses electrons) to form Fe^{3+}.

The reaction between iron and oxygen tends to be relatively slow, but other metals, such as the alkali and alkaline earth metals, react quickly upon exposure to air. **Figure 4.11** shows how the bright metallic surface of calcium tarnishes as CaO forms in the reaction

$$2\,\mathrm{Ca}(s) + \mathrm{O}_2(g) \longrightarrow 2\,\mathrm{CaO}(s) \qquad [4.22]$$

In this reaction, Ca is oxidized to Ca^{2+} and neutral O_2 is transformed to O^{2-} ions. In Equation 4.22, the oxidation involves transfer of electrons from the calcium metal to the O_2, leading to formation of CaO. When an atom, ion, or molecule becomes more negatively charged (gains electrons), we say that it is *reduced*. The gain of electrons by a substance is called **reduction**. When one reactant loses electrons (that is, when it is oxidized), another reactant must gain them. In other words, oxidation of one substance must be accompanied by reduction of some other substance. In Equation 4.22, then, molecular oxygen is reduced to oxide (O^{2-}) ions.

Go Figure How many electrons does each oxygen atom gain during the course of this reaction?



Ca(*s*) is **oxidized** (loses electrons).
$O_2(g)$ is **reduced** (gains electrons).
Ca^{2+} and O^{2-} ions combine to form CaO(*s*).

▲ **Figure 4.11** **Oxidation of calcium metal by molecular oxygen.**

Oxidation Numbers

Before we can identify an oxidation–reduction reaction, we must have a bookkeeping system—a way of keeping track of electrons gained by the substance being reduced and electrons lost by the substance being oxidized. Each atom in a neutral substance or ion is assigned an **oxidation number** (also known as an **oxidation state**). For monatomic ions, the oxidation number is the same as the charge. For neutral molecules and polyatomic ions, the oxidation number of a given atom is a hypothetical charge. This charge is assigned by artificially dividing up the electrons among the atoms in the molecule or ion. We use the following rules for assigning oxidation numbers:

1. *For an atom in its* ***elemental form****, the oxidation number is always zero*. Thus, each H atom in the H_2 molecule has an oxidation number of 0, and each P atom in the P_4 molecule has an oxidation number of 0.

2. *For any* ***monatomic ion****, the oxidation number equals the ionic charge*. Thus, K^+ has an oxidation number of +1, S^{2-} has an oxidation number of −2, and so forth.

   In ionic compounds, the alkali metal ions (group 1A) always have a 1+ charge and therefore an oxidation number of +1. The alkaline earth metals (group 2A) are always +2, and aluminum (group 3A) is always +3 in ionic compounds. (In writing oxidation numbers, we write the sign before the number to distinguish them from the actual electronic charges, which we write with the number first.)

3. ***Nonmetals*** usually have negative oxidation numbers, although they can sometimes be positive:
   (**a**) *The oxidation number of* ***oxygen*** *is usually −2 in both ionic and molecular compounds*. The major exception is in compounds called peroxides, which contain the O_2^{2-} ion, giving each oxygen an oxidation number of −1.
   (**b**) *The oxidation number of* ***hydrogen*** *is usually +1 when bonded to nonmetals and −1 when bonded to metals* (for example, metal hydrides such as sodium hydride, NaH).
   (**c**) *The oxidation number of* ***fluorine*** *is −1 in all compounds*. The other ***halogens*** have an oxidation number of −1 in most binary compounds. When combined with oxygen, as in oxyanions, however, they have positive oxidation states.

4. ***The sum of the oxidation numbers*** *of all atoms in a neutral compound is zero. The sum of the oxidation numbers in a polyatomic ion equals the charge of the ion*. For example, in the hydronium ion H_3O^+, which is a more accurate description of $H^+(aq)$, the oxidation number of each hydrogen is +1 and that of oxygen is −2. Thus, the sum of the oxidation numbers is $3(+1) + (-2) = +1$, which equals the net charge of the ion. This rule is useful in obtaining the oxidation number of one atom in a compound or ion if you know the oxidation numbers of the other atoms, as illustrated in Sample Exercise 4.8.

Sample Exercise 4.8

Determining Oxidation Numbers

Determine the oxidation number of sulfur in (**a**) H_2S, (**b**) S_8, (**c**) SCl_2, (**d**) Na_2SO_3, (**e**) SO_4^{2-}.

SOLUTION

Analyze We are asked to determine the oxidation number of sulfur in two molecular species, in the elemental form, and in two substances containing ions.

Plan In each species, the sum of oxidation numbers of all the atoms must equal the charge on the species. We will use the rules outlined previously to assign oxidation numbers.

Solve

(**a**) When bonded to a nonmetal, hydrogen has an oxidation number of +1. Because the H_2S molecule is neutral, the sum of the oxidation numbers must equal zero. Letting x equal the oxidation number of S, we have $2(+1) + x = 0$. Thus, S has an oxidation number of −2.

(**b**) Because S_8 is an elemental form of sulfur, the oxidation number of S is 0.

(**c**) Because SCl_2 is a binary compound, we expect chlorine to have an oxidation number of −1. The sum of the oxidation numbers must equal zero. Letting x equal the oxidation number of S, we have $x + 2(-1) = 0$. Consequently, the oxidation number of S must be +2.

(**d**) Sodium, an alkali metal, always has an oxidation number of +1 in its compounds. Oxygen commonly has an oxidation state of −2. Letting x equal the oxidation number of S, we have $2(+1) + x + 3(-2) = 0$. Therefore, the oxidation number of S in this compound (Na_2SO_3) is +4.

(**e**) The oxidation state of O is −2. The sum of the oxidation numbers equals −2, the net charge of the SO_4^{2-} ion. Thus, we have $x + 4(-2) = -2$, in which case the oxidation number of S is +6.

Comment These examples illustrate that the oxidation number of a given element depends on the compound in which it occurs. The oxidation numbers of sulfur, as seen in these examples, range from −2 to +6.

▶ Practice Exercise

What is the oxidation state of the boldfaced element in (**a**) $\mathbf{P}_2O_5$, (**b**) $Na\mathbf{H}$, (**c**) $\mathbf{Cr}_2O_7^{2-}$, (**d**) $\mathbf{Sn}Br_4$, (**e**) $Ba\mathbf{O}_2$?

Oxidation of Metals by Acids and Salts

The reaction between a metal and either an acid or a metal salt conforms to the general pattern

$$A + BX \longrightarrow AX + B \qquad [4.23]$$

Examples:

$$Zn(s) + 2\,HBr(aq) \longrightarrow ZnBr_2(aq) + H_2(g)$$

$$Mn(s) + Pb(NO_3)_2(aq) \longrightarrow Mn(NO_3)_2(aq) + Pb(s)$$

These reactions are also called **displacement reactions** because the ion in solution is *displaced* (replaced) through oxidation of an element.

Many metals undergo displacement reactions with acids, producing salts and hydrogen gas. For example, magnesium metal reacts with hydrochloric acid to form magnesium chloride and hydrogen gas (**Figure 4.12**):

$$\begin{array}{lccccccc} & Mg(s) & + & 2\,HCl(aq) & \longrightarrow & MgCl_2(aq) & + & H_2(g) \\ \text{Oxidation number} & 0 & & +1\;\;-1 & & +2\;\;-1 & & 0 \end{array} \qquad [4.24]$$

The oxidation number of Mg changes from 0 to +2, an increase that indicates the atom has lost electrons and has therefore been oxidized. The oxidation number of H^+ in the acid decreases from +1 to 0, indicating that this ion has gained electrons and has therefore been reduced. Chlorine has an oxidation number of −1 both before and after the

▲ **Figure 4.12 Reaction of magnesium metal with hydrochloric acid.** The metal is readily oxidized by the acid, producing hydrogen gas, $H_2(g)$, and $MgCl_2(aq)$.

reaction, indicating that it is neither oxidized nor reduced. In fact, the Cl^- ions are spectator ions, dropping out of the net ionic equation:

$$Mg(s) + 2H^+(aq) \longrightarrow Mg^{2+}(aq) + H_2(g) \qquad [4.25]$$

Metals can also be oxidized by aqueous solutions of various salts. Iron metal, for example, is oxidized to Fe^{2+} by aqueous solutions of Ni^{2+} such as $Ni(NO_3)_2(aq)$:

Molecular equation: $$Fe(s) + Ni(NO_3)_2(aq) \longrightarrow Fe(NO_3)_2(aq) + Ni(s) \qquad [4.26]$$

Net ionic equation: $$Fe(s) + Ni^{2+}(aq) \longrightarrow Fe^{2+}(aq) + Ni(s) \qquad [4.27]$$

The oxidation of Fe to Fe^{2+} in this reaction is accompanied by the reduction of Ni^{2+} to Ni. Remember: *Whenever one substance is oxidized, another substance must be reduced.*

Sample Exercise 4.9

Writing Equations for Oxidation–Reduction Reactions

Write the balanced molecular and net ionic equations for the reaction of aluminum with hydrobromic acid.

SOLUTION

Analyze We must write two equations—molecular and net ionic—for the redox reaction between a metal and an acid.

Plan Metals react with acids to form salts and H_2 gas. To write the balanced equations, we must write the chemical formulas for the two reactants and then determine the formula of the salt, which is composed of the cation formed by the metal and the anion of the acid.

Solve The reactants are Al and HBr. The cation formed by Al is Al^{3+}, and the anion from hydrobromic acid is Br^-. Thus, the salt formed in the reaction is $AlBr_3$. Writing the reactants and products and then balancing the equation gives the molecular equation:

$$2\,Al(s) + 6\,HBr(aq) \longrightarrow 2\,AlBr_3(aq) + 3\,H_2(g)$$

Both HBr and $AlBr_3$ are soluble strong electrolytes. Thus, the complete ionic equation is

$$2\,Al(s) + 6\,H^+(aq) + 6\,Br^-(aq) \longrightarrow 2\,Al^{3+}(aq) + 6\,Br^-(aq) + 3\,H_2(g)$$

Because Br^- is a spectator ion, the net ionic equation is

$$2\,Al(s) + 6\,H^+(aq) \longrightarrow 2\,Al^{3+}(aq) + 3\,H_2(g)$$

Comment The substance oxidized is the aluminum metal because its oxidation state changes from 0 in the metal to +3 in the cation, thereby increasing in oxidation number. The H^+ is reduced because its oxidation state decreases from +1 in the acid to 0 in H_2.

Practice Exercise

(**a**) Write the balanced molecular and net ionic equations for the reaction between magnesium and cobalt(II) sulfate. (**b**) Which species is oxidized, and which is reduced in the reaction?

The Activity Series

Can we predict whether a certain metal will be oxidized either by an acid or by a particular salt? This question is of both practical importance and chemical interest. According to Equation 4.26, for example, it would be unwise to store a solution of nickel nitrate in an iron container because the solution would dissolve the container. When a metal is oxidized, it forms various compounds. Extensive oxidation can lead to the failure of metal machinery parts or the deterioration of metal structures.

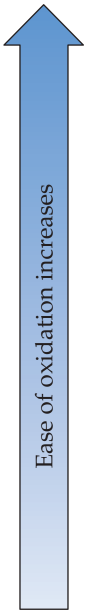
Different metals vary in the ease with which they are oxidized. Zn is oxidized by aqueous solutions of Cu^{2+}, for example, but Ag is not. Zn, therefore, loses electrons more readily than Ag; that is, Zn is easier to oxidize than Ag.

A list of metals arranged in order of decreasing ease of oxidation, such as those in **Table 4.5**, is called an **activity series**. The metals at the top of the table, such as the alkali metals and the alkaline earth metals, are most easily oxidized; that is, they react most readily to form compounds. They are called the *active metals*. The metals at the bottom of the activity series, such as the transition elements from groups 8B and 1B, are very stable and form compounds less readily. These metals, which are used to make coins and jewelry, are called *noble metals* because of their low reactivity.

The activity series can be used to predict the outcome of reactions between metals and either metal salts or acids. *Any metal on the list can be oxidized by the ions of elements below it.*

TABLE 4.5 **Activity Series of Metals in Aqueous Solution**

Metal	Oxidation Reaction
Lithium	$Li(s) \longrightarrow Li^{+}(aq) + e^{-}$
Potassium	$K(s) \longrightarrow K^{+}(aq) + e^{-}$
Barium	$Ba(s) \longrightarrow Ba^{2+}(aq) + 2e^{-}$
Calcium	$Ca(s) \longrightarrow Ca^{2+}(aq) + 2e^{-}$
Sodium	$Na(s) \longrightarrow Na^{+}(aq) + e^{-}$
Magnesium	$Mg(s) \longrightarrow Mg^{2+}(aq) + 2e^{-}$
Aluminum	$Al(s) \longrightarrow Al^{3+}(aq) + 3e^{-}$
Manganese	$Mn(s) \longrightarrow Mn^{2+}(aq) + 2e^{-}$
Zinc	$Zn(s) \longrightarrow Zn^{2+}(aq) + 2e^{-}$
Chromium	$Cr(s) \longrightarrow Cr^{3+}(aq) + 3e^{-}$
Iron	$Fe(s) \longrightarrow Fe^{2+}(aq) + 2e^{-}$
Cobalt	$Co(s) \longrightarrow Co^{2+}(aq) + 2e^{-}$
Nickel	$Ni(s) \longrightarrow Ni^{2+}(aq) + 2e^{-}$
Tin	$Sn(s) \longrightarrow Sn^{2+}(aq) + 2e^{-}$
Lead	$Pb(s) \longrightarrow Pb^{2+}(aq) + 2e^{-}$
Hydrogen	$H_2(g) \longrightarrow 2\,H^{+}(aq) + 2e^{-}$
Copper	$Cu(s) \longrightarrow Cu^{2+}(aq) + 2e^{-}$
Silver	$Ag(s) \longrightarrow Ag^{+}(aq) + e^{-}$
Mercury	$Hg(l) \longrightarrow Hg^{2+}(aq) + 2e^{-}$
Platinum	$Pt(s) \longrightarrow Pt^{2+}(aq) + 2e^{-}$
Gold	$Au(s) \longrightarrow Au^{3+}(aq) + 3e^{-}$



For example, copper is above silver in the series. Thus, copper metal is oxidized by silver ions:

$$Cu(s) + 2\,Ag^{+}(aq) \longrightarrow Cu^{2+}(aq) + 2\,Ag(s) \qquad [4.28]$$

The oxidation of copper to copper ions is accompanied by the reduction of silver ions to silver metal. The silver metal is evident on the surface of the copper wire in **Figure 4.13**. The copper(II) nitrate produces a blue color in the solution, as can be seen most clearly in the photograph on the right of Figure 4.13.

Only metals above hydrogen in the activity series are able to react with acids to form H_2. For example, Ni reacts with HCl(*aq*) to form H_2:

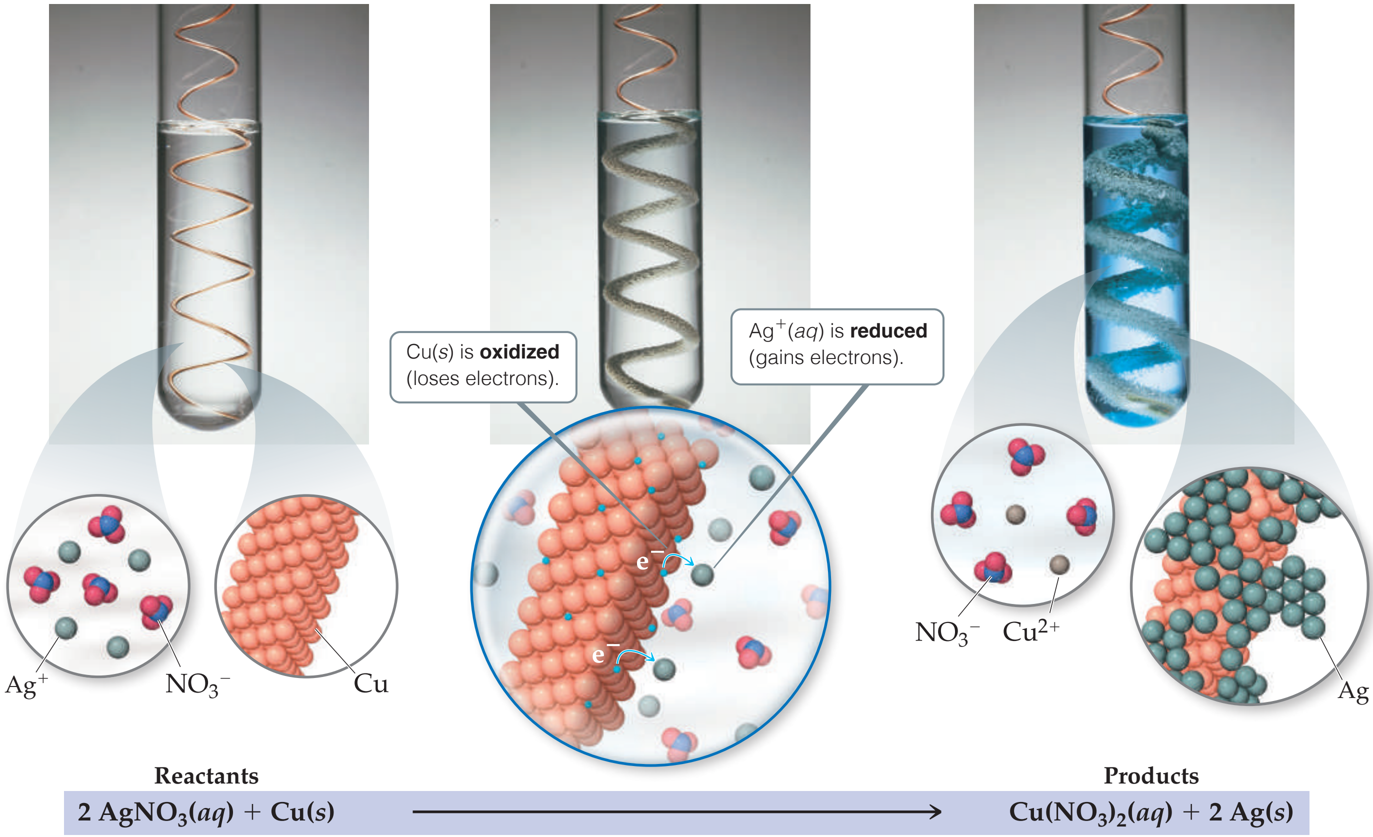
$$Ni(s) + 2\,HCl(aq) \longrightarrow NiCl_2(aq) + H_2(g) \qquad [4.29]$$

Because elements below hydrogen in the activity series are not oxidized by H^{+}, Cu does not react with HCl(*aq*). Interestingly, copper does react with nitric acid, as shown in Figure 1.11, but the reaction is not oxidation of Cu by H^{+} ions. Instead, the metal is oxidized to Cu^{2+} by the nitrate ion, accompanied by the formation of brown nitrogen dioxide, $NO_2(g)$:

$$Cu(s) + 4\,HNO_3(aq) \longrightarrow Cu(NO_3)_2(aq) + 2\,H_2O(l) + 2\,NO_2(g) \qquad [4.30]$$

As the copper is oxidized in this reaction, NO_3^{-}, where the oxidation number of nitrogen is +5, is reduced to NO_2, where the oxidation number of nitrogen is +4. We examine reactions of this type in Chapter 20.

Go Figure Why does this solution turn blue?



Cu(s) is **oxidized** (loses electrons).
Ag$^+$(aq) is **reduced** (gains electrons).
Ag$^+$

Sample Exercise 4.10

Determining If an Oxidation–Reduction Reaction Will Occur

Will an aqueous solution of iron(II) chloride oxidize magnesium metal? If so, write the balanced molecular and net ionic equations for the reaction.

SOLUTION

Analyze We are given two substances—an aqueous salt, $FeCl_2$, and a metal, Mg—and are asked if they react with each other.

Plan A reaction occurs if the reactant that is a metal in its elemental form (Mg) is located *above* the reactant that is a metal in its oxidized form (Fe^{2+}) in Table 4.5. If the reaction occurs, the Fe^{2+} ion in $FeCl_2$ is reduced to Fe, and the Mg is oxidized to Mg^{2+}.

Solve Because Mg is *above* Fe in the table, the reaction occurs. To write the formula for the salt produced in the reaction, we must remember the charges on common ions. Magnesium is always present in compounds as Mg^{2+}; the chloride ion is Cl^-. The magnesium salt formed in the reaction is $MgCl_2$, meaning the balanced molecular equation is

$$Mg(s) + FeCl_2(aq) \longrightarrow MgCl_2(aq) + Fe(s)$$

Both $FeCl_2$ and $MgCl_2$ are soluble strong electrolytes and can be written in ionic form, which shows us that Cl^- is a spectator ion in the reaction. The net ionic equation is

$$Mg(s) + Fe^{2+}(aq) \longrightarrow Mg^{2+}(aq) + Fe(s)$$

The net ionic equation shows that Mg is oxidized and Fe^{2+} is reduced in this reaction.

Check The net ionic equation is balanced with respect to both charge and mass.

▶ Practice Exercise

Which of the following metals will be oxidized by an aqueous solution of $Pb(NO_3)_2$: Zn, Cu, Fe?

Self-Assessment Exercises

SAE 4.13 Order these compounds from the minimum to maximum oxidation number for iron: Fe_2O_3, Fe, $FeCl_2$.

(**a**) $FeCl_2 < Fe < Fe_2O_3$
(**b**) $Fe_2O_3 < FeCl_2 < Fe$
(**c**) $Fe < FeCl_2 < Fe_2O_3$
(**d**) $Fe < Fe_2O_3 < FeCl_2$
(**e**) $Fe_2O_3 < FeCl_2 < Fe$

SAE 4.14 Which of the following statements about the reaction $H_2(g) + O_2(g) \longrightarrow H_2O(l)$ is true?

(**i**) This is an example of an acid–base reaction.
(**ii**) O_2 is oxidized in this reaction.
(**iii**) H_2 is reduced in this reaction.

(**a**) i only (**b**) ii only (**c**) iii only (**d**) ii and iii (**e**) None of them are true.

SAE 4.15 If a compound in which Mn is initially in the +2 oxidation state in aqueous solution is reduced, what might the product contain? (**a**) Mn(*s*) (**b**) $Mn^{4+}(aq)$ (**c**) $Mn^{6+}(aq)$ (**d**) $Mn^{7+}(aq)$

SAE 4.16 Predict what would happen if you put an aqueous solution of $CoCl_2$ in contact with the metal aluminum. (**a**) There would be no reaction. (**b**) For every Co atom oxidized, one Al atom would be reduced. (**c**) For every three Co atoms oxidized, two Al atoms would be reduced. (**d**) For every Co atom reduced, one Al atom would be oxidized. (**e**) For every three Co atoms reduced, two Al atoms would be oxidized.

STRATEGIES FOR SUCCESS Analyzing Chemical Reactions

In this chapter, you have been introduced to a great number of chemical reactions. It's not easy to get a "feel" for what happens when chemicals react. One goal of this textbook is to help you become more adept at predicting the outcomes of reactions. The key to gaining this "chemical intuition" is to learn how to categorize reactions.

Attempting to memorize individual reactions would be a futile task. It is far more fruitful to recognize patterns to determine the general category of a reaction, such as metathesis or oxidation–reduction. When faced with the challenge of predicting the outcome of a chemical reaction, ask yourself the following questions:

- What are the reactants?
- Are they electrolytes or nonelectrolytes?
- Are they acids or bases?
- If the reactants are electrolytes, will metathesis produce a precipitate? Water? A gas?
- If metathesis cannot occur, can the reactants engage in an oxidation–reduction reaction? This requires that there be both a reactant that can be oxidized and a reactant that can be reduced.

Being able to predict what happens during a reaction follows from asking basic questions like the ones above. Each question narrows the set of possible outcomes, steering you ever closer to a likely outcome. Your prediction might not always be entirely correct, but if you keep your wits about you, you will not be far off. As you gain experience, you will begin to look for reactants that might not be immediately obvious, such as water from the solution or oxygen from the atmosphere. Because proton transfer (acid–base) and electron transfer (oxidation–reduction) are involved in a huge number of chemical reactions, knowing the hallmarks of such reactions will mean you are well on your way to becoming an expert chemist.

4.5 Concentrations of Solutions

Learning Objectives

When you finish Section 4.5, you should be able to:

- ▶ Calculate the concentration of a solute in a solution in units of molarity.
- ▶ Interconvert between solute moles, solution volume, and solution molarity.
- ▶ Calculate the relative volumes of a concentrated stock solution and a solvent to mix in order to achieve a desired final volume and final concentration of a solution.

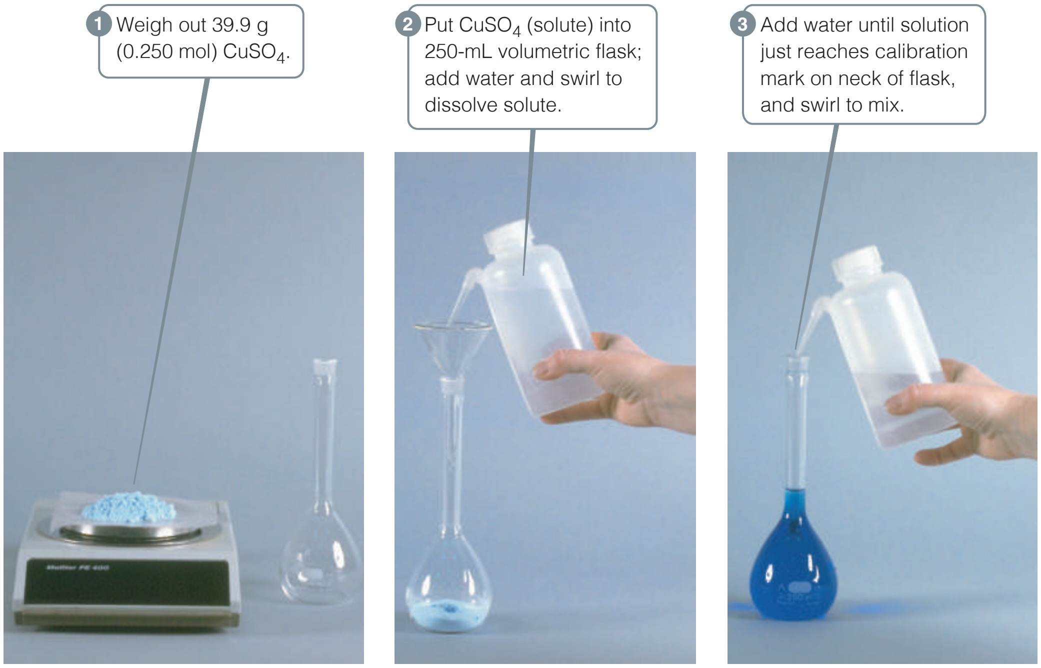
Scientists use the term **concentration** to designate the amount of solute dissolved in a given quantity of solvent or quantity of solution. The greater the amount of solute dissolved in a certain amount of solvent, the more concentrated the resulting solution. In chemistry we often need to express the concentrations of solutions quantitatively.

Molarity

Molarity (symbol *M*) expresses the concentration of a solution as the number of moles of solute in a liter of solution (soln):

$$\text{Molarity} = \frac{\text{moles solute}}{\text{volume of solution in liters}} \qquad [4.31]$$

A 1.00 molar solution (written 1.00 *M*) contains 1.00 mol of solute in every liter of solution. **Figure 4.14** shows the preparation of 0.250 L of a 1.00 *M* solution of $CuSO_4$. The molarity of the solution is $(0.250 \text{ mol } CuSO_4)/(0.250 \text{ L soln}) = 1.00\,M$. Note that we use the abbreviation "soln" for "solution."



① Weigh out 39.9 g (0.250 mol) $CuSO_4$.
② Put $CuSO_4$ (solute) into 250-mL volumetric flask; add water and swirl to dissolve solute.
③ Add water until solution just reaches calibration mark on neck of flask, and swirl to mix.

▲ **Figure 4.14** **Preparing 0.250 L of a 1.00 M solution of $CuSO_4$.**

Sample Exercise 4.11

Calculating Molarity

Calculate the molarity of a solution made by dissolving 23.4 g of sodium sulfate (Na_2SO_4) in enough water to form 125 mL of solution.

SOLUTION

Analyze We are given the number of grams of solute (23.4 g), its chemical formula (Na_2SO_4), and the volume of the solution (125 mL), and we are asked to calculate the molarity of the solution.

Plan We can calculate molarity using Equation 4.31. To do so, we must convert the number of grams of solute to moles and the volume of the solution from milliliters to liters.

Solve

The number of moles of Na_2SO_4 is obtained by using its molar mass:

$$\text{Moles } Na_2SO_4 = (23.4\ \text{g}\ \cancel{Na_2SO_4})\left(\frac{1\ \text{mol}\ Na_2SO_4}{142.1\ \text{g}\ \cancel{Na_2SO_4}}\right) = 0.165\ \text{mol}\ Na_2SO_4$$

Converting the volume of the solution to liters:

$$\text{Liters soln} = (125\ \cancel{\text{mL}})\left(\frac{1\ \text{L}}{1000\ \cancel{\text{mL}}}\right) = 0.125\ \text{L}$$

Thus, the molarity is

$$\text{Molarity} = \frac{0.165\ \text{mol}\ Na_2SO_4}{0.125\ \text{L soln}} = 1.32\ \frac{\text{mol}\ Na_2SO_4}{\text{L soln}} = 1.32\ M$$

Check Because the numerator is only slightly larger than the denominator, it is reasonable for the answer to be a little over 1 *M*. The units (mol/L) are appropriate for molarity, and three significant figures are appropriate for the answer because each of the initial pieces of data had three significant figures.

▶ Practice Exercise

Calculate the molarity of a solution made by dissolving 5.00 g of glucose ($C_6H_{12}O_6$) in sufficient water to form exactly 100 mL of solution.

Expressing the Concentration of an Electrolyte

In biology, the total concentration of ions in solution is very important in metabolic and cellular processes. When an ionic compound dissolves, the relative concentrations of the ions in the solution depend on the chemical formula of the compound. For example, a 1.0 *M* solution of NaCl is 1.0 *M* in Na^+ ions and 1.0 *M* in Cl^- ions, and a 1.0 *M* solution of Na_2SO_4 is 2.0 *M* in Na^+ ions and 1.0 *M* in SO_4^{2-} ions. Thus, the concentration of an electrolyte solution can be specified either in terms of the compound used to make the solution (1.0 *M* Na_2SO_4) or in terms of the ions in the solution (2.0 *M* Na^+ and 1.0 *M* SO_4^{2-}).

Sample Exercise 4.12

Calculating Molar Concentrations of Ions

What is the molar concentration of each ion present in a 0.025 *M* aqueous solution of calcium nitrate?

SOLUTION

Analyze We are given the concentration of the ionic compound used to make the solution and are asked to determine the concentrations of the ions in the solution.

Plan We can use the subscripts in the chemical formula of the compound to determine the relative ion concentrations.

Solve Calcium nitrate is composed of calcium ions (Ca^{2+}) and nitrate ions (NO_3^-), so its chemical formula is $Ca(NO_3)_2$. Because there are two NO_3^- ions for each Ca^{2+} ion, each mole of $Ca(NO_3)_2$ that dissolves dissociates into 1 mol of Ca^{2+} and 2 mol of NO_3^-. Thus, a solution that is 0.025 *M* in $Ca(NO_3)_2$ is 0.025 *M* in Ca^{2+} and $2 \times 0.025\,M = 0.050\,M$ in NO_3^-:

$$\frac{\text{mol } NO_3^-}{\text{L}} = \left(\frac{0.025 \text{ mol } \cancel{Ca(NO_3)_2}}{\text{L}}\right)\left(\frac{2 \text{ mol } NO_3^-}{1 \text{ mol } \cancel{Ca(NO_3)_2}}\right)$$
$$= 0.050\,M$$

Check The concentration of NO_3^- ions is twice that of Ca^{2+} ions, as the subscript 2 after the NO_3^- in the chemical formula $Ca(NO_3)_2$ suggests.

Practice Exercise

What is the molar concentration of K^+ ions in a 0.015 *M* solution of potassium carbonate?

Interconverting Molarity, Moles, and Volume

If we know any two of the three quantities in the definition of molarity (Equation 4.31), we can calculate the third. For example, if we know the molarity of an HNO_3 solution to be 0.200 *M*, which means 0.200 mol of HNO_3 per liter of solution, we can calculate the number of moles of solute in a given volume, say 2.0 L. Molarity, therefore, is a conversion factor between volume of solution and moles of solute:

$$\text{Moles } HNO_3 = (2.0\ \cancel{\text{L soln}})\left(\frac{0.200 \text{ mol } HNO_3}{1\ \cancel{\text{L soln}}}\right) = 0.40 \text{ mol } HNO_3$$

To illustrate the conversion of moles to volume, let's calculate the volume of 0.30 *M* HNO_3 solution required to supply 2.0 mol of HNO_3:

$$\text{Liters soln} = (2.0\ \cancel{\text{mol } HNO_3})\left(\frac{1 \text{ L soln}}{0.30\ \cancel{\text{mol } HNO_3}}\right) = 6.7 \text{ L soln}$$

Note that in this case we used the reciprocal of molarity in the conversion. If we examine the units in our conversion we see that:

$$\text{moles} \times (1/\text{molarity}) = \text{mol} \times (\text{L/mol}) = \text{L}$$

If one of the solutes is a liquid, we can use its density to convert its mass to volume and vice versa. For example, consider a beer that contains 5.0% ethanol (CH_3CH_2OH) by volume in water (along with other components). The density of ethanol is 0.789 g/mL. Therefore, if we wanted to calculate the molarity of ethanol (usually just called "alcohol" in everyday language) in this beer, we would first consider 1.00 L of beer.

This 1.00 L of beer contains 0.950 L of water and 0.050 L of ethanol:

$$5.0\% = 5/100 = 0.050$$

Then we can calculate the moles of ethanol by proper cancellation of units, taking into account the density of ethanol and its molar mass (46.0 g/mol):

$$\text{Moles ethanol} = (0.050\ \cancel{\text{L}})\left(\frac{1000\ \cancel{\text{mL}}}{\cancel{\text{L}}}\right)\left(\frac{0.789\ \cancel{\text{g}}}{\cancel{\text{mL}}}\right)\left(\frac{1 \text{ mol}}{46.0\ \cancel{\text{g}}}\right) = 0.858 \text{ mol}$$

Because there are 0.858 moles of ethanol in 1.00 L of beer, the concentration of ethanol in beer is 0.86 *M* (taking into account significant figures).

Sample Exercise 4.13

Using Molarity to Calculate Grams of Solute

How many grams of Na_2SO_4 are required to make 0.350 L of 0.500 M Na_2SO_4?

SOLUTION

Analyze We are given the volume of the solution (0.350 L), its concentration (0.500 M), and the identity of the solute Na_2SO_4, and we are asked to calculate the number of grams of the solute in the solution.

Plan We can use the definition of molarity (Equation 4.31) to determine the number of moles of solute, and then convert moles to grams using the molar mass of the solute.

$$M_{\text{Na}_2\text{SO}_4} = \frac{\text{moles Na}_2\text{SO}_4}{\text{liters soln}}$$

Solve Calculating the moles of Na_2SO_4 using the molarity and volume of solution gives

$$\begin{aligned}
M_{\text{Na}_2\text{SO}_4} &= \frac{\text{moles Na}_2\text{SO}_4}{\text{liters soln}}\\
\text{Moles Na}_2\text{SO}_4 &= \text{liters soln} \times M_{\text{Na}_2\text{SO}_4}\\
&= (0.350\ \cancel{\text{L soln}})\left(\frac{0.500\ \text{mol Na}_2\text{SO}_4}{1\ \cancel{\text{L soln}}}\right)\\
&= 0.175\ \text{mol Na}_2\text{SO}_4
\end{aligned}$$

Because each mole of Na_2SO_4 has a mass of 142.1 g, the required number of grams of Na_2SO_4 is

$$\begin{aligned}
\text{Grams Na}_2\text{SO}_4 &= (0.175\ \cancel{\text{mol Na}_2\text{SO}_4})\left(\frac{142.1\ \text{g Na}_2\text{SO}_4}{1\ \cancel{\text{mol Na}_2\text{SO}_4}}\right)\\
&= 24.9\ \text{g Na}_2\text{SO}_4
\end{aligned}$$

Check The magnitude of the answer, the units, and the number of significant figures are all appropriate.

▶ Practice Exercise

(**a**) How many grams of Na_2SO_4 are there in 15 mL of 0.50 M Na_2SO_4? (**b**) How many milliliters of 0.50 M Na_2SO_4 solution are needed to provide 0.038 mol of this salt?

Dilution

Solutions used routinely in the laboratory are often purchased or prepared in concentrated form (called *stock solutions*). Aqueous solutions of lower concentrations can then be obtained by adding water, a process called **dilution**.*

Let's see how we can prepare a dilute solution from a concentrated one. Suppose we want to prepare 250.0 mL (that is, 0.2500 L) of 0.100 M $CuSO_4$ solution by diluting a 1.00 M $CuSO_4$ stock solution. The main point to remember is that when solvent is added to a solution, the number of moles of solute remains unchanged:

$$\text{Moles solute before dilution} = \text{moles solute after dilution} \qquad [4.32]$$

Because we know both the volume (250.0 mL) and the concentration (0.100 mol/L) of the dilute solution, we can calculate the number of moles of $CuSO_4$ it contains:

$$\begin{aligned}
\text{Moles CuSO}_4 \text{ in dilute soln} &= (0.2500\ \cancel{\text{L soln}})\left(\frac{0.100\ \text{mol CuSO}_4}{\cancel{\text{L soln}}}\right)\\
&= 0.0250\ \text{mol CuSO}_4
\end{aligned}$$

The volume of stock solution needed to provide 0.0250 mol $CuSO_4$ is therefore:

$$\text{Liters of conc soln} = (0.0250\ \cancel{\text{mol CuSO}_4})\left(\frac{1\ \text{L soln}}{1.00\ \cancel{\text{mol CuSO}_4}}\right) = 0.0250\ \text{L}$$

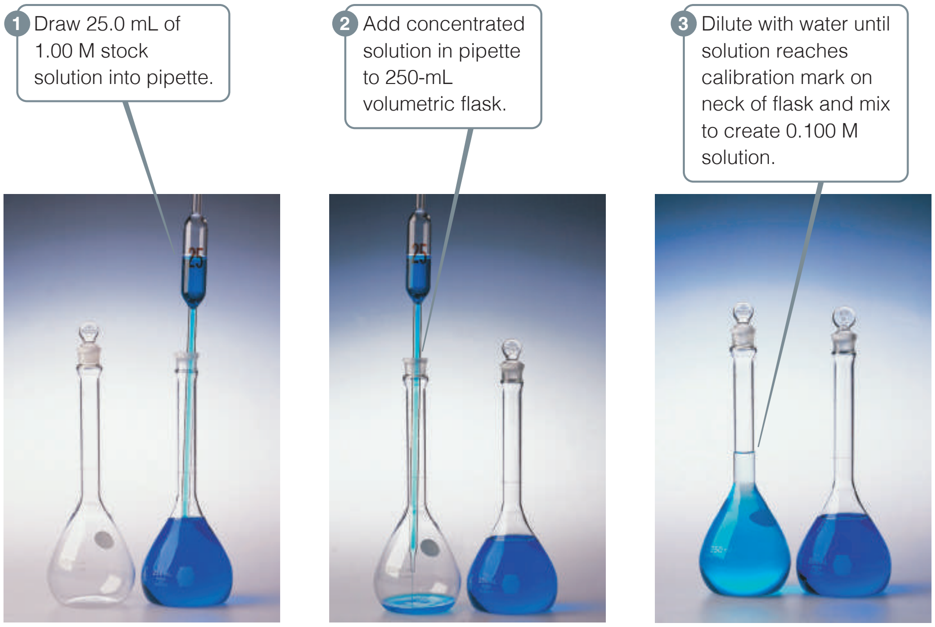
Figure 4.15 shows the dilution carried out in the laboratory. Notice that the diluted solution is less intensely colored than the concentrated one.

In laboratory situations, calculations of this sort are often made with an equation derived by remembering that the number of moles of solute is the same in both the concentrated and dilute solutions and that moles = molarity × liters:

$$\begin{aligned}
\text{Moles solute in conc soln} &= \text{moles solute in dilute soln}\\
M_{\text{conc}} \times V_{\text{conc}} &= M_{\text{dil}} \times V_{\text{dil}} \qquad [4.33]
\end{aligned}$$

---

*When diluting a concentrated acid or base, the acid or base should be added to water and then further diluted by adding more water. Adding water directly to concentrated acid or base can cause spattering because of the intense heat generated.



① Draw 25.0 mL of 1.00 M stock solution into pipette.

② Add concentrated solution in pipette to 250-mL volumetric flask.

③ Dilute with water until solution reaches calibration mark on neck of flask and mix to create 0.100 M solution.

▲ **Figure 4.15** **Preparing 250.0 mL of 0.100 *M* $CuSO_4$ by dilution of 1.00 *M* $CuSO_4$.**

Although we derived Equation 4.33 in terms of liters, any volume unit can be used as long as it is used on both sides of the equation. For example, in the calculation we did for the $CuSO_4$ solution, we have

$$(1.00\ M)(V_{\text{conc}}) = (0.100\ M)(250.0\ \text{mL})$$

Solving for V_{conc} gives $V_{\text{conc}} = 25.0\ \text{mL}$ as before.

Sample Exercise 4.14

Preparing a Solution by Dilution

How many milliliters of 3.0 *M* H_2SO_4 are needed to make 450 mL of 0.10 *M* H_2SO_4?

SOLUTION

Analyze We need to dilute a concentrated solution. We are given the molarity of a more concentrated solution (3.0 *M*) and the volume and molarity of a more dilute one containing the same solute (450 mL of 0.10 *M* solution). We must calculate the volume of the concentrated solution needed to prepare the dilute solution.

Plan We can calculate the number of moles of solute, H_2SO_4, in the dilute solution and then calculate the volume of the concentrated solution needed to supply this amount of solute. Alternatively, we can directly apply Equation 4.33. Let's compare the two methods.

Solve

Calculate the moles of H_2SO_4 in the dilute solution:

$$\text{Moles } H_2SO_4 \text{ in dilute solution} = (0.450\ \cancel{\text{L soln}})\left(\frac{0.10\ \text{mol } H_2SO_4}{1\ \cancel{\text{L soln}}}\right)$$
$$= 0.045\ \text{mol } H_2SO_4$$

Calculate the volume of the concentrated solution that contains 0.045 mol H_2SO_4:

$$\text{Liters conc soln} = (0.045\ \cancel{\text{mol } H_2SO_4})\left(\frac{1\ \text{L soln}}{3.0\ \cancel{\text{mol } H_2SO_4}}\right) = 0.015\ \text{L soln}$$

Converting liters to milliliters gives 15 mL.

If we apply Equation 4.33, we get the same result:

$$(3.0\ M)(V_{\text{conc}}) = (0.10\ M)(450\ \text{mL})$$
$$(V_{\text{conc}}) = \frac{(0.10\ \cancel{M})(450\ \text{mL})}{3.0\ \cancel{M}} = 15\ \text{mL}$$

Either way, we see that if we start with 15 mL of 3.0 *M* H_2SO_4 and dilute it to a total volume of 450 mL, the desired 0.10 *M* solution will be obtained.

Check The calculated volume seems reasonable because a small volume of concentrated solution is used to prepare a large volume of dilute solution.

Comment The first approach can also be used to find the final concentration when two solutions of different concentrations are mixed, whereas the second approach, using Equation 4.33, can be used only for diluting a concentrated solution with pure solvent.

▶ **Practice Exercise**

(**a**) What volume of 2.50 *M* lead(II) nitrate solution contains 0.0500 mol of Pb^{2+}? (**b**) How many milliliters of 5.0 *M* $K_2Cr_2O_7$ solution must be diluted to prepare 250 mL of 0.10 *M* solution? (**c**) If 10.0 mL of a 10.0 *M* stock solution of NaOH is diluted to 250 mL, what is the concentration of the resulting stock solution?

Self-Assessment Exercises

SAE 4.17 What is the molarity of a solution that is made by dissolving 4.60 grams of methanol, CH_3OH, in water to a final volume of 1.85 L?

(**a**) 2.49 *M*
(**b**) 1.44×10^{-1} *M*

(**d**) 7.77×10^{-2} *M*
(**e**) 1.26×10^{-2} *M*

SAE 4.18 Which solution will have the largest concentration of ions? (**a**) 1.0 *M* NaCl (**b**) 1.4 *M* $NaNO_3$ (**c**) 1.0 *M* $CaCl_2$ (**d**) 0.6 *M* Na_3PO_4

SAE 4.19 A normal blood glucose ($C_6H_{12}O_6$) level is 85 mg glucose/dL. What is the concentration in units of molarity?

(**a**) 4.7 *M*
(**b**) 2.1 *M*
(**c**) 4.7×10^{-3} *M*
(**d**) 4.7×10^{-4} *M*

SAE 4.20 What volume of a 5.0×10^{-1} *M* stock solution of Na_3PO_4 must be used to make 250 mL of a solution that is 3.8×10^{-3} *M* in phosphate ions? (**a**) 0.0075 mL (**b**) 0.63 mL (**c**) 1.9 mL (**d**) 3.3 mL

4.6 | Solution Stoichiometry and Chemical Analysis

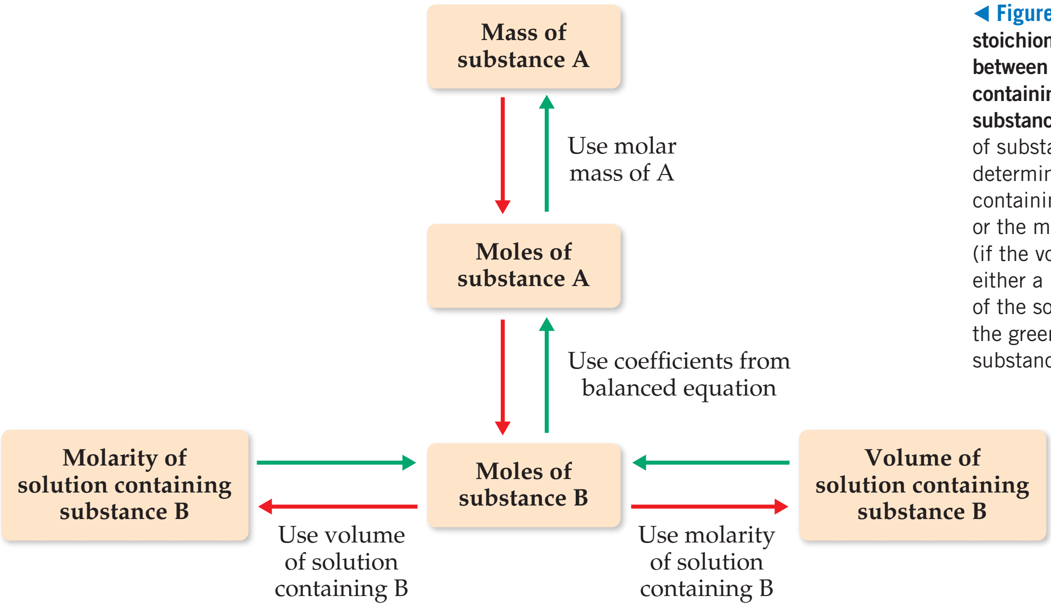
In Chapter 3 we learned that given the chemical equation for a reaction and the amount of one reactant consumed in the reaction, you can calculate the quantities of other reactants and products. In this section we extend this concept to reactions involving solutions.

Recall that the coefficients in a balanced equation give the relative number of moles of reactants and products. (Section 3.6) To use this information, we must convert the masses of substances involved in a reaction into moles. When dealing with pure substances, as we did in Chapter 3, we use molar mass to convert between grams and moles of the substances. This conversion is not valid when working with a solution because both solute and solvent contribute to its mass. However, if we know the solute concentration, we can use molarity and volume to determine the number of moles (moles solute = *M* × *V*). **Figure 4.16** summarizes this approach to using stoichiometry for the reaction between a pure substance and a solution.

Learning Objectives

When you finish Section 4.6, you should be able to:

- ▶ Calculate stoichiometric quantities for reactions in aqueous solutions.
- ▶ Use acid–base titrations to calculate quantities of solutes.



Mass of substance A
Use molar mass of A
Moles of substance A
Use coefficients from balanced equation
Molarity of solution containing substance B
Moles of substance B
Volume of solution containing substance B
Use volume of solution containing B
Use molarity of solution containing B

◀ **Figure 4.16 Procedure for solving stoichiometry problems involving reactions between a pure substance A and a solution containing a known concentration of substance B.** Starting from a known mass of substance A, we follow the red arrows to determine either the volume of the solution containing B (if the molarity of B is known) or the molarity of the solution containing B (if the volume of B is known). Starting from either a known volume or a known molarity of the solution containing B, we follow the green arrows to determine the mass of substance A.

Sample Exercise 4.15

Using Mass Relations in a Neutralization Reaction

How many grams of $Ca(OH)_2$ are needed to neutralize 25.0 mL of 0.100 M HNO_3?

SOLUTION

Analyze The reactants are an acid, HNO_3, and a base, $Ca(OH)_2$. The volume and molarity of HNO_3 are given, and we are asked how many grams of $Ca(OH)_2$ are needed to neutralize this quantity of HNO_3.

Plan Following the steps outlined by the green arrows in Figure 4.16, we use the molarity and volume of the HNO_3 solution (substance B in Figure 4.16) to calculate the number of moles of HNO_3. We then use the balanced equation to relate moles of HNO_3 to moles of $Ca(OH)_2$ (substance A). Finally, we use the molar mass to convert moles to grams of $Ca(OH)_2$:

$$V_{HNO_3} \times M_{HNO_3} \Rightarrow \text{mol } HNO_3 \Rightarrow \text{mol } Ca(OH)_2 \Rightarrow \text{g } Ca(OH)_2$$

Solve

The product of the molar concentration of a solution and its volume in liters gives the number of moles of solute:

$$\text{Moles } HNO_3 = V_{HNO_3} \times M_{HNO_3} = (0.0250\,\cancel{L})\left(\frac{0.100 \text{ mol } HNO_3}{\cancel{L}}\right)$$
$$= 2.50 \times 10^{-3} \text{mol } HNO_3$$

Because this is a neutralization reaction, HNO_3 and $Ca(OH)_2$ react to form H_2O and the salt containing Ca^{2+} and NO_3^-:

$$2\,HNO_3(aq) + Ca(OH)_2(s) \longrightarrow 2\,H_2O(l) + Ca(NO_3)_2(aq)$$

Thus, 2 mol HNO_3 $\bumpeq$ 1 mol $Ca(OH)_2$. Therefore,

$$\text{Grams } Ca(OH)_2 = (2.50 \times 10^{-3}\,\cancel{\text{mol } HNO_3}) \times \left(\frac{1\,\cancel{\text{mol } Ca(OH)_2}}{2\,\cancel{\text{mol } HNO_3}}\right)\left(\frac{74.1 \text{ g } Ca(OH)_2}{1\,\cancel{\text{mol } Ca(OH)_2}}\right)$$
$$= 0.0926 \text{ g } Ca(OH)_2$$

Check The answer is reasonable because a small volume of dilute acid requires only a small amount of base to neutralize it.

▶ Practice Exercise

(**a**) How many grams of NaOH are needed to neutralize 20.0 mL of 0.150 M H_2SO_4 solution? (**b**) How many liters of 0.500 M $HCl(aq)$ are needed to react completely with 0.100 mol of $Pb(NO_3)_2(aq)$, forming a precipitate of $PbCl_2(s)$?

Titrations

To determine the concentration of a particular solute in a solution, chemists often carry out a **titration**, which involves combining a solution where the solute concentration is not known with a reagent solution of known concentration, called a **standard solution**. Just enough standard solution is added to completely react with the solute in the solution of unknown concentration. The point at which stoichiometrically equivalent quantities are brought together is known as the **equivalence point**. You will likely carry out at least one titration experiment in the laboratory portion of your course.

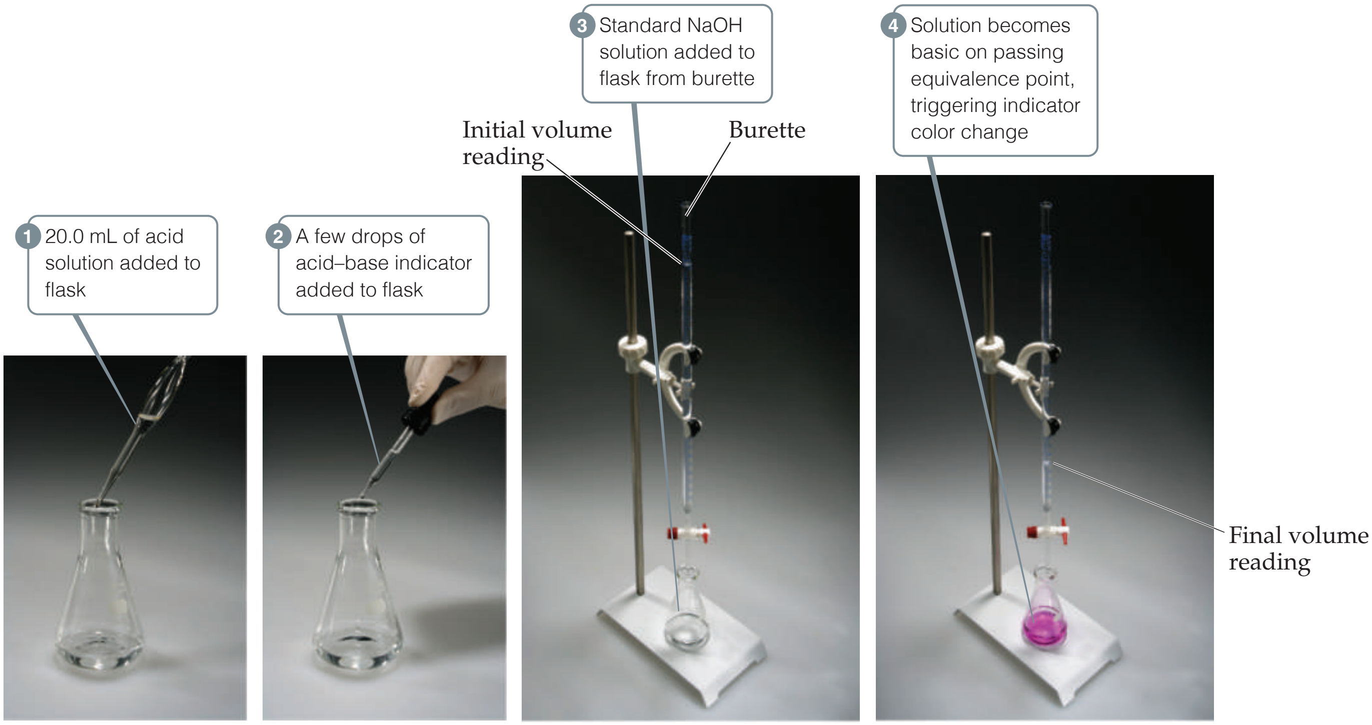
Titrations can be conducted using neutralization, precipitation, or oxidation–reduction reactions. **Figure 4.17** illustrates a typical neutralization titration, one between an HCl solution of unknown concentration and a standard NaOH solution. To determine the HCl concentration, we first add a specific volume of the HCl solution, 20.0 mL in this example, to a flask. Next we add a few drops of an acid–base **indicator**. The acid–base indicator is a dye that changes color on passing the equivalence point.* For example, the dye phenolphthalein is colorless in acidic solution but pink in basic solution. The standard solution is then slowly added until the solution turns pink, thereby indicating that the neutralization reaction between HCl and NaOH is complete. The standard solution is added from a *burette* so that we can accurately determine the added volume of NaOH solution. Knowing the volumes of both solutions and the concentration of the standard solution, we can calculate the concentration of the unknown solution as diagrammed in **Figure 4.18**.

---

*More precisely, the color change of an indicator signals the end point of the titration, which if the proper indicator is chosen lies very near the equivalence point. Acid–base titrations are discussed in more detail in Section 17.3.

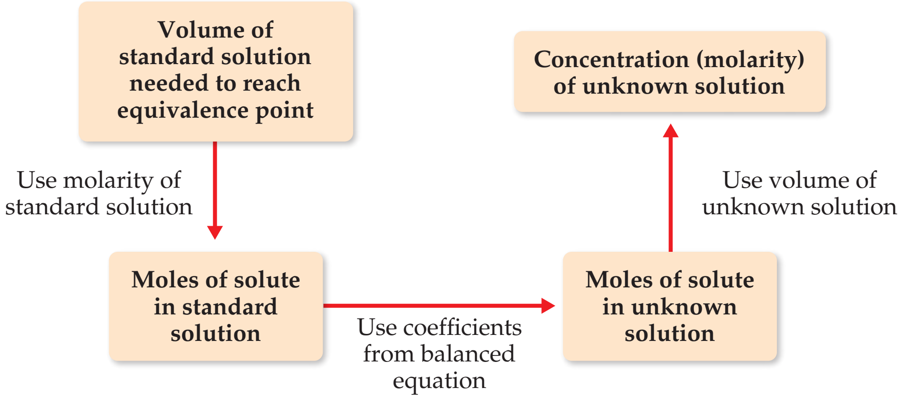
Go Figure

How would the volume of standard solution added change if that solution were $Ba(OH)_2(aq)$ instead of $NaOH(aq)$?



① 20.0 mL of acid solution added to flask
② A few drops of acid–base indicator added to flask
③ Standard NaOH solution added to flask from burette
④ Solution becomes basic on passing equivalence point, triggering indicator color change
Initial volume reading
Burette
Final volume reading

▲ **Figure 4.17 Procedure for titrating an acid against a standard solution of NaOH.** The acid–base indicator, phenolphthalein, is colorless in acidic solution but takes on a pink color in basic solution.



Volume of standard solution needed to reach equivalence point
Use molarity of standard solution
Moles of solute in standard solution
Use coefficients from balanced equation
Moles of solute in unknown solution
Use volume of unknown solution
Concentration (molarity) of unknown solution

Sample Exercise 4.16

Determining Solution Concentration by an Acid–Base Titration

One commercial method used to peel potatoes is to soak them in a NaOH solution for a short time and then remove the potatoes and spray off the peel. The NaOH concentration is normally 3 to 6 *M*, and the solution must be analyzed periodically. In one such analysis, 45.7 mL of 0.500 *M* H_2SO_4 is required to neutralize 20.0 mL of NaOH solution. What is the concentration of the NaOH solution?

SOLUTION

Analyze We are given the volume (45.7 mL) and molarity (0.500 *M*) of an H_2SO_4 solution (the standard solution) that reacts completely with 20.0 mL of NaOH solution. We are asked to calculate the molarity of the NaOH solution.

Plan Following the steps given in Figure 4.18, we use the H_2SO_4 volume and molarity to calculate the number of moles of H_2SO_4. Then we can use this quantity and the balanced equation for the reaction to calculate moles of NaOH. Finally, we can use moles of NaOH and the NaOH volume to calculate NaOH molarity.

Continued

Solve

The number of moles of H_2SO_4 is the product of the volume and molarity of this solution:

$$\text{Moles } \mathrm{H_2SO_4} = (45.7\ \cancel{\mathrm{mL\ soln}})\left(\frac{1\ \cancel{\mathrm{L\ soln}}}{1000\ \cancel{\mathrm{mL\ soln}}}\right)\left(\frac{0.500\ \mathrm{mol\ H_2SO_4}}{\cancel{\mathrm{L\ soln}}}\right)$$
$$= 2.28 \times 10^{-2}\ \mathrm{mol\ H_2SO_4}$$

Acids react with metal hydroxides to form water and a salt. Thus, the balanced equation for the neutralization reaction is

$$\mathrm{H_2SO_4}(aq) + 2\,\mathrm{NaOH}(aq) \longrightarrow 2\,\mathrm{H_2O}(l) + \mathrm{Na_2SO_4}(aq)$$

According to the balanced equation, $1\ \mathrm{mol\ H_2SO_4} \simeq 2\ \mathrm{mol\ NaOH}$. Therefore,

$$\text{Moles NaOH} = (2.28 \times 10^{-2}\ \cancel{\mathrm{mol\ H_2SO_4}})\left(\frac{2\ \mathrm{mol\ NaOH}}{1\ \cancel{\mathrm{mol\ H_2SO_4}}}\right)$$
$$= 4.56 \times 10^{-2}\ \mathrm{mol\ NaOH}$$

Knowing the number of moles of NaOH in 20.0 mL of solution allows us to calculate the molarity of this solution:

$$\text{Molarity NaOH} = \frac{\mathrm{mol\ NaOH}}{\mathrm{L\ soln}}$$
$$= \left(\frac{4.56 \times 10^{-2}\ \mathrm{mol\ NaOH}}{20.0\ \cancel{\mathrm{mL\ soln}}}\right)\left(\frac{1000\ \cancel{\mathrm{mL\ soln}}}{1\ \mathrm{L\ soln}}\right)$$
$$= 2.28\ \frac{\mathrm{mol\ NaOH}}{\mathrm{L\ soln}} = 2.28\ M$$

Practice Exercise

What is the molarity of a NaOH solution if 48.0 mL neutralizes 35.0 mL of 0.144 M H_2SO_4?

Sample Exercise 4.17

Determining the Quantity of Solute by Titration

The quantity of Cl^- in a municipal water supply is determined by titrating the sample with Ag^+. The precipitation reaction taking place during the titration is

$$\mathrm{Ag^+}(aq) + \mathrm{Cl^-}(aq) \longrightarrow \mathrm{AgCl}(s)$$

(**a**) How many grams of chloride ion are in a sample of the water if 20.2 mL of 0.100 M Ag^+ is needed to react with all the chloride in the sample? (**b**) If the sample has a mass of 10.0 g, what percentage of Cl^- does it contain?

SOLUTION

Analyze We are given the volume (20.2 mL) and molarity (0.100 M) of a solution of Ag^+ and the chemical equation for reaction of this ion with Cl^-. We are asked to calculate the number of grams of Cl^- in the sample and the mass percentage of Cl^- in the sample.

Plan (**a**) We can use the procedure outlined by the green arrows in Figure 4.16. We begin by using the volume and molarity of Ag^+ to calculate the number of moles of Ag^+ used in the titration. We then use the balanced equation to determine the moles of Cl^- in the sample and from that the grams of Cl^-. (**b**) To calculate the percentage of Cl^- in the sample, we compare the number of grams of Cl^- in the sample with the original mass of the sample, 10.0 g.

Solve

(**a**) Calculate the number of moles of Ag^+ used in the titration.

$$\text{Moles } \mathrm{Ag^+} = (20.2\ \cancel{\mathrm{mL\ soln}})\left(\frac{1\ \cancel{\mathrm{L\ soln}}}{1000\ \cancel{\mathrm{mL\ soln}}}\right)\left(\frac{0.100\ \mathrm{mol\ Ag^+}}{\cancel{\mathrm{L\ soln}}}\right)$$
$$= 2.02 \times 10^{-3}\ \mathrm{mol\ Ag^+}$$

According to the balanced equation, $1\ \mathrm{mol\ Ag^+} \simeq 1\ \mathrm{mol\ Cl^-}$. Using this information and the molar mass of Cl, we have:

$$\text{Grams } \mathrm{Cl^-} = (2.02 \times 10^{-3}\ \cancel{\mathrm{mol\ Ag^+}})\left(\frac{1\ \cancel{\mathrm{mol\ Cl^-}}}{1\ \cancel{\mathrm{mol\ Ag^+}}}\right)\left(\frac{35.5\ \mathrm{g\ Cl^-}}{\cancel{\mathrm{mol\ Cl^-}}}\right)$$
$$= 7.17 \times 10^{-2}\ \mathrm{g\ Cl^-}$$

(**b**) Calculate the percentage of Cl^- used in the sample.

$$\text{Percent } \mathrm{Cl^-} = \frac{7.17 \times 10^{-2}\ \mathrm{g}}{10.0\ \mathrm{g}} \times 100\% = 0.717\%\ \mathrm{Cl^-}$$

Practice Exercise

A sample of an iron ore is dissolved in acid, and the iron is converted to Fe^{2+}. The sample is then titrated with 47.20 mL of 0.02240 *M* MnO_4^- solution. The oxidation–reduction reaction that occurs during titration is

$$MnO_4^-(aq) + 5\,Fe^{2+}(aq) + 8\,H^+(aq) \longrightarrow Mn^{2+}(aq) + 5\,Fe^{3+}(aq) + 4\,H_2O(l)$$

(**a**) How many moles of MnO_4^- were added to the solution? (**b**) How many moles of Fe^{2+} were in the sample? (**c**) How many grams of iron were in the sample? (**d**) If the sample had a mass of 0.8890 g, what is the percentage of iron in the sample?

Self-Assessment Exercises

SAE 4.21 A 3.0-mL sample of a $6.42 \times 10^{-2}\,M$ NH_3 solution is mixed with 2.0 mL of a $7.85 \times 10^{-2}\,M$ HCl solution. After purification, what is the theoretical yield of ammonium chloride? (**a**) 0 mg, because all components are soluble (**b**) 2.7 mg (**c**) 8.4 mg (**d**) 10.3 mg

SAE 4.22 How many kilograms of barium hydroxide are required to neutralize 50.0 L of a 0.125 *M* formic acid solution? (Formic acid, HCOOH, is a monoprotic acid.) (**a**) 0.535 kg (**b**) 1.07 kg (**c**) 34.3 kg (**d**) 68.5 kg

SAE 4.23 Biologically active weak bases include cocaine (molar mass 303.3 g/mol), the neurotransmitter dopamine (molar mass 153.2 g/mol), and the psychedelic drug 2,5-dimethoxy-4-methylamphetamine (molar mass 202.3 g/mol). A sample of 1.7 g of one of these substances is dissolved in 500.0 mL water, and this solution requires 56.0 mL of 0.100 *M* HCl to neutralize. Which weak base was in the solution? (**a**) cocaine (**b**) dopamine (**c**) 2,5-dimethoxy-4-methylamphetamine (**d**) It is not possible to figure this out with the given information.

Putting Concepts Together

A sample of 70.5 mg of potassium phosphate is added to 15.0 mL of 0.050 *M* silver nitrate, resulting in the formation of a precipitate. (**a**) Write the molecular equation for the reaction. (**b**) What is the limiting reactant in the reaction? (**c**) Calculate the theoretical yield, in grams, of the precipitate that forms.

SOLUTION

(**a**) Potassium phosphate and silver nitrate are both ionic compounds. Potassium phosphate contains K^+ and PO_4^{3-} ions, so its chemical formula is K_3PO_4. Silver nitrate contains Ag^+ and NO_3^- ions, so its chemical formula is $AgNO_3$. Because both reactants are strong electrolytes, the solution contains K^+, PO_4^{3-}, Ag^+, and NO_3^- ions before the reaction occurs. According to the solubility guidelines in Table 4.1, Ag^+ and PO_4^{3-} form an insoluble compound, so Ag_3PO_4 will precipitate from the solution. In contrast, K^+ and NO_3^- will remain in solution because KNO_3 is water soluble. Thus, the balanced molecular equation for the reaction is

$$K_3PO_4(aq) + 3\,AgNO_3(aq) \longrightarrow Ag_3PO_4(s) + 3\,KNO_3(aq)$$

(**b**) To determine the limiting reactant, we must examine the number of moles of each reactant. (Section 3.7) The number of moles of K_3PO_4 is calculated from the mass of the sample using the molar mass as a conversion factor. (Section 3.4) The molar mass of K_3PO_4 is $3(39.1) + 31.0 + 4(16.0) = 212.3\ g/mol$. Converting milligrams to grams and then to moles, we have:

$$(70.5\ \cancel{mg\ K_3PO_4})\left(\frac{10^{-3}\ \cancel{g\ K_3PO_4}}{1\ \cancel{mg\ K_3PO_4}}\right)\left(\frac{1\ mol\ K_3PO_4}{212.3\ \cancel{g\ K_3PO_4}}\right)$$
$$= 3.32 \times 10^{-4}\ mol\ K_3PO_4$$

We determine the number of moles of $AgNO_3$ from the volume and molarity of the solution. (Section 4.5) Converting milliliters to liters and then to moles, we have:

$$(15.0\ \cancel{mL})\left(\frac{10^{-3}\ \cancel{L}}{1\ \cancel{mL}}\right)\left(\frac{0.050\ mol\ AgNO_3}{\cancel{L}}\right)$$
$$= 7.5 \times 10^{-4}\ mol\ AgNO_3$$

Comparing the amounts of the two reactants, we find that there are $(7.5 \times 10^{-4})/(3.32 \times 10^{-4}) = 2.3$ times as many moles of $AgNO_3$ as there are moles of K_3PO_4. According to the balanced equation, however, 1 mol K_3PO_4 requires 3 mol $AgNO_3$. Thus, there is insufficient $AgNO_3$ to consume the K_3PO_4, and $AgNO_3$ is the limiting reactant.

Continued

(**c**) The precipitate is Ag_3PO_4, whose molar mass is $3(107.9) + 31.0 + 4(16.0) = 418.7$ g/mol. To calculate the number of grams of Ag_3PO_4 that could be produced in this reaction (the theoretical yield), we use the number of moles of the limiting reactant, converting mol $AgNO_3 \Rightarrow$ mol $Ag_3PO_4 \Rightarrow$ g Ag_3PO_4. We use the coefficients in the balanced equation to convert moles of $AgNO_3$ to moles Ag_3PO_4, and we use the molar mass of Ag_3PO_4 to convert the number of moles of this substance to grams.

The answer has only two significant figures because the quantity of $AgNO_3$ is given to only two significant figures.

$$(7.5 \times 10^{-4}\ \cancel{\text{mol AgNO}_3})\left(\frac{1\ \cancel{\text{mol Ag}_3\text{PO}_4}}{3\ \cancel{\text{mol AgNO}_3}}\right)\left(\frac{418.7\ \text{g Ag}_3\text{PO}_4}{1\ \cancel{\text{mol Ag}_3\text{PO}_4}}\right)$$

$$= 0.10\ \text{g Ag}_3\text{PO}_4$$

Chapter Summary and Key Terms

GENERAL PROPERTIES OF AQUEOUS SOLUTIONS (INTRODUCTION AND SECTION 4.1) Solutions in which water is the dissolving medium are called **aqueous solutions**. The component of the solution that is present in the greatest quantity is the **solvent**. The other components are **solutes**.

Any substance whose aqueous solution contains ions is called an **electrolyte**. Any substance that forms a solution containing no ions is a **nonelectrolyte**. Electrolytes that are present in solution entirely as ions are **strong electrolytes**, whereas those that are present partly as ions and partly as molecules are **weak electrolytes**. Ionic compounds dissociate into ions when they dissolve, so they are **strong electrolytes**. The solubility of ionic substances is made possible by **solvation**, the interaction of ions with polar solvent molecules. Most molecular compounds are nonelectrolytes, although some are weak electrolytes and a few are strong electrolytes. When representing the ionization of a weak electrolyte in solution, half-arrows in both directions are used, indicating that the forward and reverse reactions can achieve a chemical balance called a **chemical equilibrium**.

PRECIPITATION REACTIONS (SECTION 4.2) **Precipitation reactions** are those in which an insoluble product, called a **precipitate**, forms. Solubility guidelines (see Table 4.1) help determine whether an ionic compound will be soluble in water. (The **solubility** of a substance is the amount that dissolves in a given quantity of solvent.) Reactions such as precipitation reactions, in which cations and anions appear to exchange partners, are called **exchange reactions**, or **metathesis reactions**.

Chemical equations can be written to show whether dissolved substances are present in solution predominantly as ions or molecules. When the complete chemical formulas of all reactants and products are used, the equation is called a **molecular equation**. A **complete ionic equation** shows all dissolved strong electrolytes as their component ions. In a **net ionic equation**, those ions that go through the reaction unchanged (**spectator ions**) are omitted.

ACIDS, BASES, AND NEUTRALIZATION REACTIONS (SECTION 4.3) Acids and bases are important electrolytes. **Acids** are proton donors; they increase the concentration of $H^+(aq)$ in aqueous solutions to which they are added. **Bases** are proton acceptors; they increase the concentration of $OH^-(aq)$ in aqueous solutions. Those acids and bases that are strong electrolytes are called **strong acids** and **strong bases**, respectively. Those that are weak electrolytes are **weak acids** and **weak bases**. When solutions of acids and bases are mixed, a neutralization reaction occurs. The **neutralization reaction** between an acid and a metal hydroxide produces water and a **salt**. Gases can also be formed as a result of neutralization reactions. The reaction of a sulfide with an acid forms $H_2S(g)$; the reaction between a carbonate and an acid forms $CO_2(g)$.

OXIDATION–REDUCTION REACTIONS (SECTION 4.4) **Oxidation** is the loss of electrons by a substance, whereas **reduction** is the gain of electrons by a substance. **Oxidation numbers** (or **oxidation states**) keep track of electrons during chemical reactions and are assigned to atoms using specific rules. The oxidation of an element results in an increase in its oxidation number, whereas reduction is accompanied by a decrease in oxidation number. Oxidation is always accompanied by reduction, giving **oxidation–reduction**, or **redox, reactions**.

Many metals are oxidized by O_2, acids, and salts. The redox reactions between metals and acids as well as those between metals and salts are called **displacement reactions**. The products of these displacement reactions are always an element (H_2 or a metal) and a salt. Comparing such reactions allows us to rank metals according to their ease of oxidation. A list of metals arranged in order of decreasing ease of oxidation is called an **activity series**. Any metal on the list can be oxidized by ions of metals (or H^+) below it in the series.

CONCENTRATIONS OF SOLUTIONS (SECTION 4.5) The **concentration** of a solution expresses the amount of a solute dissolved in the solution. One of the common ways to express the concentration of a solute is in terms of molarity. The **molarity** of a solution is the number of moles of solute per liter of solution. Molarity makes it possible to interconvert solution volume and number of moles of solute. If the solute is a liquid, its density can be used in molarity calculations to convert between mass, volume, and moles. Solutions of known molarity can be formed either by weighing out the solute and diluting it to a known volume or by the **dilution** of a more concentrated solution of known concentration (a stock solution). Adding solvent to the solution (the process of dilution) decreases the concentration of the solute without changing the number of moles of solute in the solution ($M_{\text{conc}} \times V_{\text{conc}} = M_{\text{dil}} \times V_{\text{dil}}$).

SOLUTION STOICHIOMETRY AND CHEMICAL ANALYSIS (SECTION 4.6) In the common laboratory technique called **titration**, we combine a solution of known concentration (a **standard solution**) with a solution of unknown concentration to determine the unknown concentration or the quantity of solute in the unknown. The point in the titration at which stoichiometrically equivalent quantities of reactants are brought together is called the **equivalence point**. An indicator can be used to show the end point of the titration, which coincides closely with the equivalence point.

Key Equations

- $\text{Molarity} = \dfrac{\text{moles solute}}{\text{volume of solution in liters}}$ [4.31] Molarity is the most commonly used unit of concentration in chemistry.
- $M_{\text{conc}} \times V_{\text{conc}} = M_{\text{dil}} \times V_{\text{dil}}$ [4.33] When adding solvent to a concentrated solution to make a dilute solution, molarities and volumes of both concentrated and dilute solutions can be calculated if three of the quantities are known.

Exam Prep

EP 4.1 If you have an aqueous solution that contains 1.5 moles of HCl, how many moles of ions are in the solution? (**a**) 1.0 (**b**) 1.5 (**c**) 2.0 (**d**) 2.5 (**e**) 3.0

EP 4.2 Which of the following compounds is insoluble in water? (**a**) $(NH_4)_2S$ (**b**) $CaCO_3$ (**c**) NaOH (**d**) Ag_2SO_4 (**e**) $Pb(CH_3COO)_2$

EP 4.3 What precipitate forms when solutions of $Ba(NO_3)_2$ and KOH are mixed? (**a**) BaOH (**b**) KNO_3 (**c**) $K_2(NO_3)$ (**d**) $Ba(OH)_2$ (**e**) No precipitate will form.

EP 4.4 What happens when you mix an aqueous solution of sodium nitrate with an aqueous solution of barium chloride? (**a**) There is no reaction; all possible products are soluble. (**b**) Only barium nitrate precipitates. (**c**) Only sodium chloride precipitates. (**d**) Both barium nitrate and sodium chloride precipitate. (**e**) Nothing; barium chloride is not soluble and it remains as a precipitate.

EP 4.5 A set of aqueous solutions are prepared containing different acids at the same concentration: acetic acid, chloric acid, and hydrobromic acid. Which solution(s) are the most electrically conductive? (**a**) chloric acid (**b**) hydrobromic acid (**c**) acetic acid (**d**) both chloric acid and hydrobromic acid (**e**) all three solutions have the same electrical conductivity.

EP 4.6 Which of these substances, when dissolved in water, is a strong electrolyte? (**a**) ammonia (**b**) hydrofluoric acid (**c**) folic acid (**d**) sodium nitrate (**e**) sucrose.

EP 4.7 Which is the correct net ionic equation for the reaction of aqueous ammonia with nitric acid?

(**a**) $NH_4^+(aq) + H^+(aq) \longrightarrow NH_5^{2+}(aq)$
(**b**) $NH_3(aq) + NO_3^-(aq) \longrightarrow NH_2^-(aq) + HNO_3(aq)$
(**c**) $NH_2^-(aq) + H^+(aq) \longrightarrow NH_3(aq)$
(**d**) $NH_3(aq) + H^+(aq) \longrightarrow NH_4^+(aq)$
(**e**) $NH_4^+(aq) + NO_3^-(aq) \longrightarrow NH_4NO_3(aq)$

EP 4.8 In which compound is the oxidation state of oxygen −1? (**a**) O_2 (**b**) H_2O (**c**) H_2SO_4 (**d**) H_2O_2 (**e**) KCH_3COO

EP 4.9 Which of the following statements about the reaction between zinc and copper sulfate is true? (**a**) Zinc is oxidized, and copper ion is reduced. (**b**) Zinc is reduced, and copper ion is oxidized. (**c**) All reactants and products are soluble strong electrolytes. (**d**) The oxidation state of copper in copper sulfate is 0. (**e**) More than one of the previous choices are true.

EP 4.10 Which of these metals is the easiest to oxidize? (**a**) gold (**b**) lithium (**c**) iron (**d**) sodium (**e**) aluminum

EP 4.11 What is the molarity of a solution that is made by dissolving 3.68 g of sucrose $(C_{12}H_{22}O_{11})$ in sufficient water to form 275.0 mL of solution?

(**a**) 13.4 M
(**b**) $7.43 \times 10^{-2}\,M$
(**c**) $3.91 \times 10^{-2}\,M$
(**d**) $7.43 \times 10^{-5}\,M$
(**e**) $3.91 \times 10^{-5}\,M$

EP 4.12 What is the ratio of the concentration of potassium ions to the concentration of carbonate ions in a 0.015 M solution of potassium carbonate? (**a**) 1:0.015 (**b**) 0.015:1 (**c**) 1:1 (**d**) 1:2 (**e**) 2:1

EP 4.13 What is the concentration of ammonia in a solution made by dissolving 3.75 g of ammonia in 120.0 L of water?

(**a**) $1.84 \times 10^{-3}\,M$
(**b**) $3.78 \times 10^{-2}\,M$
(**c**) 0.0313 M
(**d**) 1.84 M
(**e**) 7.05 M

EP 4.14 What volume of a 1.00 M stock solution of glucose must be used to make 500.0 mL of a $1.75 \times 10^{-2}\,M$ glucose solution in water? (**a**) 1.75 mL (**b**) 8.75 mL (**c**) 48.6 mL (**d**) 57.1 mL (**e**) 28,570 mL

EP 4.15 How many milligrams of sodium sulfide are needed to completely react with 25.00 mL of a 0.0100 M aqueous solution of cadmium nitrate, to form a precipitate of $CdS(s)$? (**a**) 13.8 mg (**b**) 19.5 mg (**c**) 23.5 mg (**d**) 32.1 mg (**e**) 39.0 mg

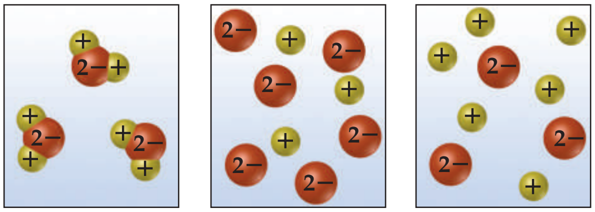
EP 4.16 What is the molarity of an HCl solution if 27.3 mL of it neutralizes 134.5 mL of 0.0165 M $Ba(OH)_2$? (**a**) 0.0444 M (**b**) 0.0813 M (**c**) 0.163 M (**d**) 0.325 M (**e**) 3.35 M

EP 4.17 A mysterious white powder is found at a crime scene. A simple chemical analysis concludes that the powder is a mixture of sugar and morphine $(C_{17}H_{19}NO_3)$, a weak base similar to ammonia that has only one protonable nitrogen. The crime lab takes 10.00 mg of the mysterious white powder, dissolves it in 100.00 mL water, and titrates it to the equivalence point with 2.84 mL of a standard 0.0100 M HCl solution. What is the mass percentage of morphine in the white powder? (**a**) 8.10% (**b**) 17.3% (**c**) 32.6% (**d**) 49.7% (**e**) 81.0%.

Exercises

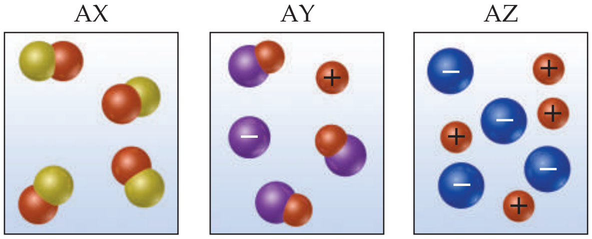
Visualizing Concepts

4.1 Which of the following schematic drawings best describes a solution of Li_2SO_4 in water (water molecules are not shown for simplicity)? [Section 4.1]



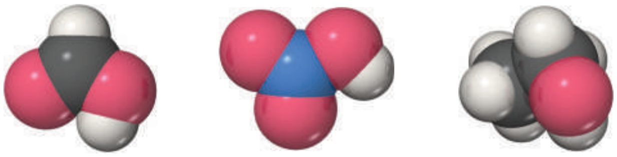
(a) (b) (c)

4.2 Aqueous solutions of three different substances, AX, AY, and AZ, are represented by the three accompanying diagrams. Identify each substance as a strong electrolyte, a weak electrolyte, or a nonelectrolyte. [Section 4.1]



(a) (b) (c)

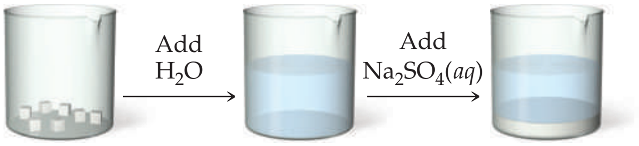
4.3 Use the molecular representations shown here to classify each compound as a nonelectrolyte, a weak electrolyte, or a strong electrolyte (see Figure 4.5 for the element color scheme). [Sections 4.1 and 4.3]



(a) (b) (c)

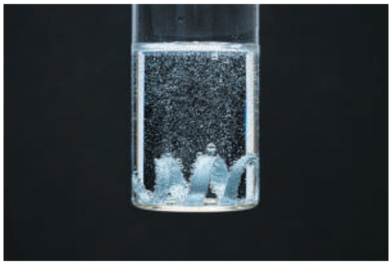
4.4 The concept of chemical equilibrium is very important. Which one of the following statements is the most correct way to think about equilibrium? (**a**) If a system is at equilibrium, nothing is happening. (**b**) If a system is at equilibrium, the rate of the forward reaction is equal to the rate of the back reaction. (**c**) If a system is at equilibrium, the product concentration is changing over time. [Section 4.1]

4.5 You are presented with a white solid and told that due to careless labeling it is not clear if the substance is barium chloride, lead chloride, or zinc chloride. When you transfer the solid to a beaker and add water, the solid dissolves to give a clear solution. Next a $Na_2SO_4(aq)$ solution is added and a white precipitate forms. What is the identity of the unknown white solid? [Section 4.2]



4.6 Which of the following ions will *always* be a spectator ion in a precipitation reaction? (**a**) Cl^- (**b**) NO_3^- (**c**) NH_4^+ (**d**) S^{2-} (**e**) SO^{2-} [Section 4.2]

4.7 When a metal strip is placed in $HCl(aq)$, a reaction occurs as indicated by the bubbles of gas formed on the surface of the metal. Which of the following could be the identities of the metal and the gas involved in this reaction? (**a**) Pt, H_2 (**b**) Pt, O_2 (**c**) Zn, H_2 (**d**) Zn, O_2 (**e**) Fe, Cl_2 [Section 4.4]

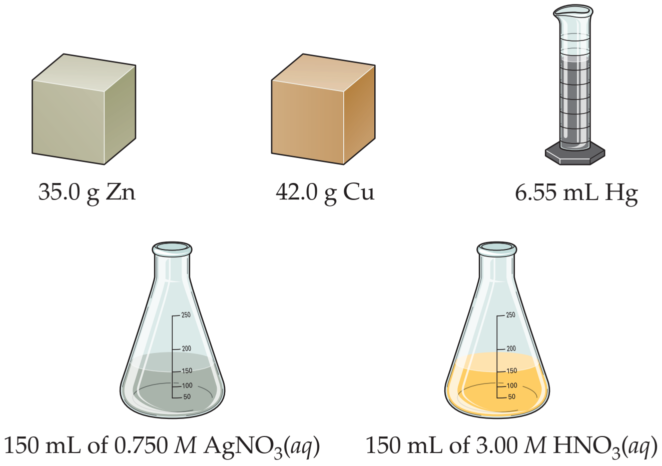


4.8 Which of these statements is true? (**a**) If a compound is oxidized, it is gaining electrons. (**b**) If a base is neutralized, it is gaining protons. (**c**) Elements that are metals cannot be oxidized. (**d**) If hydrogen gas is generated in a reaction, it must be an acid–base reaction. [Sections 4.3 and 4.4]

4.9 What kind of reaction is this? $N_2(g) + 3H_2(g) \longrightarrow 2NH_3(g)$ (**a**) an acid–base reaction (**b**) a metathesis reaction (**c**) a redox reaction (**d**) a precipitation reaction [Section 4.4]

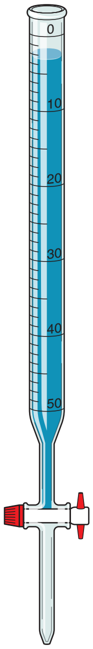
4.10 An aqueous solution contains 1.2 mM of total ions. (**a**) If the solution is $NaCl(aq)$, what is the concentration of chloride ion? (**b**) If the solution is $FeCl_3(aq)$, what is the concentration of chloride ion? [Section 4.5]

4.11 Consider the following reagents shown below: zinc, copper, mercury (density 13.6 g/mL), silver nitrate solution, nitric acid solution. (**a**) Given a 500-mL Erlenmeyer flask and a balloon, how can you combine two or more of the reagents to initiate a chemical reaction that will inflate the balloon? Write a balanced chemical equation to represent this process. (**b**) What is the identity of the substance that inflates the balloon? (**c**) What is the theoretical yield of the substance that fills the balloon? [Section 4.5]



35.0 g Zn
42.0 g Cu
6.55 mL Hg
150 mL of 0.750 M $AgNO_3(aq)$
150 mL of 3.00 M $HNO_3(aq)$

4.12 In a titration experiment, 50.0 mL of 0.075 *M* acetic acid, CH_3COOH, is titrated with the 0.250 *M* KOH(*aq*) that is in the burette. The drawing shows the level of the KOH in the burette before the titration begins. What will be the burette reading at the equivalence point? [Section 4.6]



General Properties of Aqueous Solutions (Section 4.1)

4.13 State whether each of the following statements is true or false. (**a**) Electrolyte solutions conduct electricity because electrons are moving through the solution. (**b**) If you add a nonelectrolyte to an aqueous solution that already contains an electrolyte, the electrical conductivity will not change.

4.14 State whether each of the following statements is true or false. (**a**) When methanol, CH_3OH, is dissolved in water, a conducting solution results. (**b**) When acetic acid, CH_3COOH, dissolves in water, the solution is weakly conducting and acidic in nature.

4.15 We have learned in this chapter that many ionic solids dissolve in water as strong electrolytes, that is, as separated ions in solution. Which statement is most correct about this process? (**a**) Water is a strong acid and therefore is good at dissolving ionic solids. (**b**) Water is good at solvating ions because the hydrogen and oxygen atoms in water molecules bear partial charges. (**c**) The hydrogen and oxygen bonds of water are easily broken by ionic solids.

4.16 Would you expect that an anion would be physically closer to the oxygen or to the hydrogens of water molecules that surround it in solution?

4.17 Specify what ions are present in solution upon dissolving each of the following substances in water: (**a**) $FeCl_2$, (**b**) HNO_3, (**c**) $(NH_4)_2SO_4$, (**d**) $Ca(OH)_2$.

4.18 Specify what ions are present upon dissolving each of the following substances in water: (**a**) MgI_2, (**b**) K_2CO_3, (**c**) $HClO_4$, (**d**) $NaCH_3COO$.

4.19 Formic acid, HCOOH, is a weak electrolyte. What solutes are present in an aqueous solution of this compound? Write the chemical equation for the ionization of HCOOH.

4.20 Acetone, CH_3COCH_3, is a nonelectrolyte; hypochlorous acid, HClO, is a weak electrolyte; and ammonium chloride, NH_4Cl, is a strong electrolyte. (**a**) What are the solutes present in aqueous solutions of each compound? (**b**) If 0.1 mol of each compound is dissolved in solution, which one contains 0.2 mol of solute particles, which contains 0.1 mol of solute particles, and which contains somewhere between 0.1 and 0.2 mol of solute particles?

Precipitation Reactions (Section 4.2)

4.21 Using solubility guidelines, predict whether each of the following compounds is soluble or insoluble in water: (**a**) $MgBr_2$, (**b**) PbI_2, (**c**) $(NH_4)_2CO_3$, (**d**) $Sr(OH)_2$, (**e**) $ZnSO_4$.

4.22 Predict whether each of the following compounds is soluble in water: (**a**) AgI, (**b**) Na_2CO_3, (**c**) $BaCl_2$, (**d**) $Al(OH)_3$, (**e**) $Zn(CH_3COO)_2$.

4.23 Will precipitation occur when the following solutions are mixed? If so, write a balanced chemical equation for the reaction. (**a**) Na_2CO_3 and $AgNO_3$ (**b**) $NaNO_3$ and $NiSO_4$ (**c**) $FeSO_4$ and $Pb(NO_3)_2$

4.24 Identify the precipitate (if any) that forms when the following solutions are mixed, and write a balanced equation for each reaction. (**a**) $NaCH_3COO$ and HCl (**b**) KOH and $Cu(NO_3)_2$ (**c**) Na_2S and $CdSO_4$

4.25 Which ions remain in solution, unreacted, after each of the following pairs of solutions is mixed? (**a**) potassium carbonate and magnesium sulfate (**b**) lead nitrate and lithium sulfide (**c**) ammonium phosphate and calcium chloride

4.26 Write balanced net ionic equations for the reactions that occur in each of the following cases. Identify the spectator ion or ions in each reaction.

(**a**) $Cr_2(SO_4)_3(aq) + (NH_4)_2CO_3(aq) \longrightarrow$

(**b**) $Ba(NO_3)_2(aq) + K_2SO_4(aq) \longrightarrow$

(**c**) $Fe(NO_3)_2(aq) + KOH(aq) \longrightarrow$

4.27 Separate samples of a solution of an unknown salt are treated with dilute solutions of HBr, H_2SO_4, and NaOH. A precipitate forms in all three cases. Which of the following cations could be present in the unknown salt solution: K^+, Pb^{2+}, Ba^{2+}?

4.28 Separate samples of a solution of an unknown ionic compound are treated with dilute $AgNO_3$, $Pb(NO_3)_2$, and $BaCl_2$. Precipitates form in all three cases. Which of the following could be the anion of the unknown salt: Br^-, CO_3^{2-}, or NO_3^-?

4.29 You know that an unlabeled bottle contains an aqueous solution of one of the following: $AgNO_3$, $CaCl_2$, or $Al_2(SO_4)_3$. You take a portion of the solution and add an aqueous solution of $Ba(NO_3)_2$ to it, and observe that a white solid precipitates Then you take another portion of the unlabeled solution and add an aqueous solution of NaCl to it; nothing appears to happen. What is the most likely identity of the solution in the unlabeled bottle: (**a**) silver nitrate, (**b**) calcium chloride, (**c**) aluminum sulfate?

4.30 Three solutions are mixed together to form a single solution; in the final solution, there are 0.2 mol $Pb(CH_3COO)_2$, 0.1 mol Na_2S, and 0.1 mol $CaCl_2$ present. What solid(s) will precipitate?

Acids, Bases, and Neutralization Reactions (Section 4.3)

4.31 Which of the following solutions is the most acidic? (**a**) 0.2 *M* LiOH (**b**) 0.2 *M* HI (**c**) 1.0 *M* methanol (CH_3OH)

4.32 Which of the following solutions is the most basic? (**a**) 0.6 *M* NH_3 (**b**) 0.150 *M* KOH (**c**) 0.100 *M* $Ba(OH)_2$

4.33 State whether each of the following statements is true or false. Justify your answer in each case. (**a**) Sulfuric acid is a monoprotic acid. (**b**) HCl is a weak acid. (**c**) Methanol is a base.

4.34 State whether each of the following statements is true or false. Justify your answer in each case. (**a**) NH_3 contains no OH^- ions, and yet its aqueous solutions are basic. (**b**) HF is a strong acid. (**c**) Although sulfuric acid is a strong electrolyte, an aqueous solution of H_2SO_4 contains more HSO_4^- ions than SO_4^{2-} ions.

4.35 Label each of the following substances as an acid, base, salt, or none of the above. Indicate whether the substance exists in aqueous solution entirely in molecular form, entirely as ions, or as a mixture of molecules and ions. (**a**) HF (**b**) acetonitrile CH_3CN (**c**) $NaClO_4$ (**d**) $Ba(OH)_2$

4.36 An aqueous solution of an unknown solute is tested with litmus paper and found to be acidic. The solution is weakly conducting compared with a solution of NaCl of the same concentration. Which of the following substances could the unknown be: KOH, NH_3, HNO_3, $KClO_2$, H_3PO_3, CH_3COCH_3 (acetone)?

4.37 Classify each of the following substances as a nonelectrolyte, weak electrolyte, or strong electrolyte in water: (**a**) H_2SO_3, (**b**) CH_3CH_2OH (ethanol), (**c**) NH_3, (**d**) $KClO_3$, (**e**) $Cu(NO_3)_2$.

4.38 Classify each of the following aqueous solutions as a nonelectrolyte, weak electrolyte, or strong electrolyte: (**a**) $LiClO_4$, (**b**) HClO, (**c**) $CH_3CH_2CH_2OH$ (propanol), (**d**) $HClO_3$, (**e**) $CuSO_4$, (**f**) $C_{12}H_{22}O_{11}$ (sucrose).

4.39 Complete and balance the following molecular equations, and then write the net ionic equation for each.

(**a**) $HBr(aq) + Ca(OH)_2(aq) \longrightarrow$

(**b**) $Cu(OH)_2(s) + HClO_4(aq) \longrightarrow$

(**c**) $Al(OH)_3(s) + HNO_3(aq) \longrightarrow$

4.40 Write the balanced molecular and net ionic equations for each of the following neutralization reactions: (**a**) Aqueous acetic acid is neutralized by aqueous barium hydroxide. (**b**) Solid chromium(III) hydroxide reacts with nitrous acid. (**c**) Aqueous nitric acid and aqueous ammonia react.

4.41 Write balanced molecular and net ionic equations for the following reactions, and identify the gas formed in each: (**a**) solid cadmium sulfide reacts with an aqueous solution of sulfuric acid; (**b**) solid magnesium carbonate reacts with an aqueous solution of perchloric acid.

4.42 Because the oxide ion is basic, metal oxides react readily with acids.

(**a**) Write the net ionic equation for the following reaction:

$$FeO(s) + 2\,HClO_4(aq) \longrightarrow Fe(ClO_4)_2(aq) + H_2O(l)$$

(**b**) Based on the equation in part (**a**), write the net ionic equation for the reaction that occurs between NiO(s) and an aqueous solution of nitric acid.

4.43 Magnesium carbonate and magnesium hydroxide are white solids that react with acidic solutions. Write the net ionic equations for the reaction that occurs when each substance reacts with a hydrochloric acid solution.

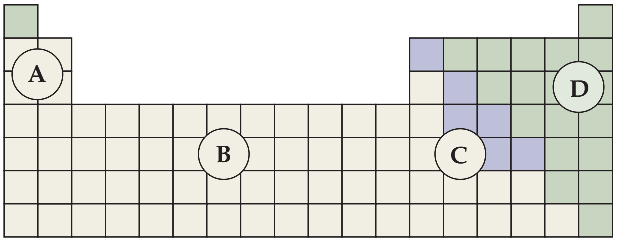
4.44 As K_2O dissolves in water, the oxide ion reacts with water molecules to form hydroxide ions. (**a**) Write the molecular and net ionic equations for this reaction. (**b**) Based on the definitions of acid and base, what ion is the base in this reaction? (**c**) What is the acid in the reaction? (**d**) What is the spectator ion in the reaction?

Oxidation–Reduction Reactions (Section 4.4)

4.45 True or false: (**a**) If a substance is oxidized, it is gaining electrons. (**b**) If an ion is oxidized, its oxidation number increases.

4.46 True or false: (**a**) Oxidation can occur without oxygen. (**b**) Oxidation can occur without reduction.

4.47 (**a**) Which region of the periodic table shown here contains elements that are easiest to oxidize? (**b**) Which region contains the least readily oxidized elements?



4.48 Determine the oxidation number of sulfur in each of the following substances: (**a**) barium sulfate, $BaSO_4$, (**b**) sulfurous acid, H_2SO_3, (**c**) strontium sulfide, SrS, (**d**) hydrogen sulfide, H_2S. (**e**) Locate sulfur in the periodic table in Exercise 4.47; what region is it in? (**f**) Which region(s) of the periodic table contains elements that can adopt both positive and negative oxidation numbers?

4.49 Determine the oxidation number for the indicated element in each of the following substances: (**a**) S in SO_2, (**b**) C in $COCl_2$, (**c**) Mn in $KMnO_4$, (**d**) Br in HBrO, (**e**) P in PF_3, (**f**) O in K_2O_2.

4.50 Determine the oxidation number for the indicated element in each of the following compounds: (**a**) Co in $LiCoO_2$, (**b**) Al in $NaAlH_4$, (**c**) C in CH_3OH (methanol), (**d**) N in GaN, (**e**) Cl in $HClO_2$, (**f**) Cr in $BaCrO_4$.

4.51 Which element is oxidized, and which is reduced in the following reactions?

(**a**) $N_2(g) + 3\,H_2(g) \longrightarrow 2\,NH_3(g)$

(**b**) $3\,Fe(NO_3)_2(aq) + 2\,Al(s) \longrightarrow 3\,Fe(s) + 2\,Al(NO_3)_3(aq)$

(**c**) $Cl_2(aq) + 2\,NaI(aq) \longrightarrow I_2(aq) + 2\,NaCl(aq)$

(**d**) $PbS(s) + 4\,H_2O_2(aq) \longrightarrow PbSO_4(s) + 4\,H_2O(l)$

4.52 Which of the following are redox reactions? For those that are, indicate which element is oxidized and which is reduced. For those that are not, indicate whether they are precipitation or neutralization reactions.

(**a**) $P_4(s) + 10\,HClO(aq) + 6\,H_2O(l) \longrightarrow 4\,H_3PO_4(aq) + 10\,HCl(aq)$

(**b**) $Br_2(l) + 2\,K(s) \longrightarrow 2\,KBr(s)$

(**c**) $CH_3CH_2OH(l) + 3\,O_2(g) \longrightarrow 3\,H_2O(l) + 2\,CO_2(g)$

(**d**) $ZnCl_2(aq) + 2\,NaOH(aq) \longrightarrow Zn(OH)_2(s) + 2\,NaCl(aq)$

4.53 Write balanced net ionic equations for the reactions of (**a**) tin with hydrochloric acid, (**b**) aluminum with formic acid, HCOOH. *Hint*: These reactions produce a gas.

4.54 Write balanced net ionic equations for the reactions of (**a**) hydrochloric acid with nickel, (**b**) dilute sulfuric acid with iron. *Hint*: These reactions produce a gas.

4.55 Using the activity series (Table 4.5), write balanced chemical equations for the following reactions. If no reaction occurs, write NR. (**a**) iron metal is added to a solution of copper(II) nitrate (**b**) zinc metal is added to a solution of magnesium sulfate (**c**) hydrobromic acid is added to tin metal (**d**) hydrogen gas is bubbled through an aqueous solution of nickel(II) chloride (**e**) aluminum metal is added to a solution of cobalt(II) sulfate

4.56 Using the activity series (Table 4.5), write balanced chemical equations for the following reactions. If no reaction occurs, write NR. (**a**) nickel metal is added to a solution of copper(II) nitrate (**b**) a solution of zinc nitrate is added to a solution of magnesium sulfate (**c**) hydrochloric acid is added to gold metal (**d**) chromium metal is immersed in an aqueous solution of cobalt(II) chloride (**e**) hydrogen gas is bubbled through a solution of silver nitrate.

4.57 The metal cadmium tends to form Cd^{2+} ions. The following observations are made:

(**i**) When a strip of zinc metal is placed in $CdCl_2(aq)$, cadmium metal is deposited on the strip.

(**ii**) When a strip of cadmium metal is placed in $Ni(NO_3)_2(aq)$, nickel metal is deposited on the strip.

(**a**) Write net ionic equations to explain each of the preceding observations. (**b**) Is cadmium above or below zinc in the activity series? (**c**) Is cadmium above or below nickel in the activity series?

4.58 The following reactions (note that the arrows are pointing in only one direction) can be used to prepare an activity series for the halogens:

$$Br_2(aq) + 2\,NaI(aq) \longrightarrow 2\,NaBr(aq) + I_2(aq)$$

$$Cl_2(aq) + 2\,NaBr(aq) \longrightarrow 2\,NaCl(aq) + Br_2(aq)$$

(**a**) Which elemental halogen would you predict is the most stable, upon mixing with other halides? (**b**) Predict whether a reaction will occur when elemental chlorine and potassium iodide are mixed. (**c**) Predict whether a reaction will occur when elemental bromine and lithium chloride are mixed.

Concentrations of Solutions (Section 4.5)

4.59 (**a**) Is the concentration of a solution an intensive or an extensive property? (**b**) What is the difference between 0.50 mol HCl and 0.50 *M* HCl?

4.60 You make 1.000 L of an aqueous solution that contains 35.0 g of sucrose ($C_{12}H_{22}O_{11}$). (**a**) What is the molarity of sucrose in this solution? (**b**) How many liters of water would you have to add to this solution to reduce the molarity you calculated in part (a) by a factor of two?

4.61 (**a**) Calculate the molarity of a solution that contains 0.175 mol $ZnCl_2$ in exactly 150 mL of solution. (**b**) How many moles of protons are present in 35.0 mL of a 4.50 *M* solution of nitric acid? (**c**) How many milliliters of a 6.00 *M* NaOH solution are needed to provide 0.350 mol of NaOH?

4.62 (**a**) Calculate the molarity of a solution made by dissolving 12.5 grams of Na_2CrO_4 in enough water to form exactly 750 mL of solution. (**b**) How many moles of KBr are present in 150 mL of a 0.112 *M* solution? (**c**) How many milliliters of 6.1 *M* HCl solution are needed to obtain 0.150 mol of HCl?

4.63 The average adult human male has a total blood volume of 5.0 L. If the concentration of sodium ion in this average individual is 0.135 *M*, what is the mass of sodium ion circulating in the blood?

4.64 A person suffering from hyponatremia has a sodium ion concentration in the blood of 0.118 *M* and a total blood volume of 4.6 L. What mass of sodium chloride would need to be added to the blood to bring the sodium ion concentration up to 0.138 *M*, assuming no change in blood volume?

4.65 The concentration of alcohol (CH_3CH_2OH) in blood, called the "blood alcohol concentration" or BAC, is given in units of grams of alcohol per 100 mL of blood. The legal definition of intoxication, in many states of the United States, is that the BAC is 0.08 or higher. What is the molar concentration of alcohol in blood if the BAC is 0.08?

4.66 The average adult male has a total blood volume of 5.0 L. After drinking a few beers, he has a BAC of 0.10 (see Exercise 4.65). What mass of alcohol is circulating in his blood?

4.67 (**a**) How many grams of ethanol, CH_3CH_2OH, should you dissolve in water to make 1.00 L of vodka (which is an aqueous solution that is 6.86 *M* ethanol)? (**b**) Using the density of ethanol (0.789 g/mL), calculate the volume of ethanol you need to make 1.00 L of vodka.

4.68 One cup of fresh orange juice contains 124 mg of ascorbic acid (vitamin C, $C_6H_8O_6$). Given that one cup = 236.6 mL, calculate the molarity of vitamin C in orange juice.

4.69 (**a**) Which will have the highest concentration of potassium ion: 0.20 *M* KCl, 0.15 *M* K_2CrO_4, or 0.080 *M* K_3PO_4? (**b**) Which will contain the greater number of moles of potassium ion: 30.0 mL of 0.15 *M* K_2CrO_4 or 25.0 mL of 0.080 *M* K_3PO_4?

4.70 In each of the following pairs, indicate which has the higher concentration of I^- ion: (**a**) 0.10 *M* BaI_2 or 0.25 *M* KI solution, (**b**) 100 mL of 0.10 *M* KI solution or 200 mL of 0.040 *M* ZnI_2 solution, (**c**) 3.2 *M* HI solution or a solution made by dissolving 145 g of NaI in water to make 150 mL of solution.

4.71 Indicate the concentration of each ion or molecule present in the following solutions: (**a**) 0.25 *M* $NaNO_3$, (**b**) 1.3×10^{-2} *M* $MgSO_4$, (**c**) 0.0150 *M* $C_6H_{12}O_6$, (**d**) a mixture of 45.0 mL of 0.272 *M* NaCl and 65.0 mL of 0.0247 *M* $(NH_4)_2CO_3$. Assume that the volumes are additive.

4.72 Indicate the concentration of each ion present in the solution formed by mixing (**a**) 42.0 mL of 0.170 *M* NaOH with 37.6 mL of 0.400 *M* NaOH, (**b**) 44.0 mL of 0.100 *M* Na_2SO_4 with 25.0 mL of 0.150 *M* KCl, (**c**) 3.60 g KCl in 75.0 mL of 0.250 *M* $CaCl_2$ solution. Assume that the volumes are additive.

4.73 (**a**) You have a stock solution of 14.8 *M* NH_3. How many milliliters of this solution should you dilute to make 1000.0 mL of 0.250 *M* NH_3? (**b**) If you take a 10.0-mL portion of the stock solution and dilute it to a total volume of 0.500 L, what will be the concentration of the final solution?

4.74 (**a**) How many milliliters of a stock solution of 6.0 *M* HNO_3 would you have to use to prepare 110 mL of 0.500 *M* HNO_3? (**b**) If you dilute 10.0 mL of the stock solution to a final volume of 0.250 L, what will be the concentration of the diluted solution?

4.75 A medical lab is testing a new anticancer drug on cancer cells. The drug stock solution concentration is 1.5×10^{-9} *M*, and 1.00 mL of this solution will be delivered to a dish containing 2.0×10^5 cancer cells in 5.00 mL of aqueous fluid. What is the ratio of drug molecules to the number of cancer cells in the dish?

4.76 Calicheamicin gamma-1, $C_{55}H_{74}IN_3O_{21}S_4$, is one of the most potent antibiotics known: one molecule kills one bacterial cell. Describe how you would (carefully!) prepare 25.00 mL of an aqueous calicheamicin gamma-1 solution that could kill 1.0×10^8 bacteria, starting from a 5.00×10^{-9} *M* stock solution of the antibiotic.

4.77 Pure acetic acid, known as glacial acetic acid, is a liquid with a density of 1.049 g/mL at 25 °C. Calculate the molarity of a solution of acetic acid made by dissolving 20.00 mL of glacial acetic acid at 25 °C in enough water to make 250.0 mL of solution.

4.78 Glycerol, $C_3H_8O_3$, is a substance used extensively in the manufacture of cosmetics, foodstuffs, antifreeze, and plastics. Glycerol is a water-soluble liquid with a density of 1.2656 g/mL at 15 °C. Calculate the molarity of a solution of glycerol made by dissolving 50.000 mL glycerol at 15 °C in enough water to make 250.00 mL of solution.

Solution Stoichiometry and Chemical Analysis (Section 4.6)

4.79 You want to analyze a silver nitrate solution. (**a**) You could add HCl(*aq*) to the solution to precipitate out AgCl(*s*). What volume of a 0.150 *M* HCl(*aq*) solution is needed to precipitate the silver ions from 15.0 mL of a 0.200 *M* $AgNO_3$ solution? (**b**) You could add solid KCl to the solution to precipitate out AgCl(*s*). What mass of KCl is needed to precipitate the silver ions from 15.0 mL of 0.200 *M* $AgNO_3$ solution? (**c**) Given that a 0.150 *M* HCl(*aq*) solution costs $39.95 for 500 mL and that KCl costs $10/ton, which analysis procedure is more cost-effective?

4.80 You want to analyze a cadmium nitrate solution. What mass of NaOH is needed to precipitate the Cd^{2+} ions from 35.0 mL of 0.500 *M* $Cd(NO_3)_2$ solution?

4.81 (**a**) What volume of 0.115 M $HClO_4$ solution is needed to neutralize 50.00 mL of 0.0875 M NaOH? (**b**) What volume of 0.128 M HCl is needed to neutralize 2.87 g of $Mg(OH)_2$? (**c**) If 25.8 mL of an $AgNO_3$ solution is needed to precipitate all the Cl^- ions in a 785-mg sample of KCl (forming AgCl), what is the molarity of the $AgNO_3$ solution? (**d**) If 45.3 mL of a 0.108 M HCl solution is needed to neutralize a solution of KOH, how many grams of KOH must be present in the solution?

4.82 (**a**) How many milliliters of 0.120 M HCl are needed to completely neutralize 50.0 mL of 0.101 M $Ba(OH)_2$ solution? (**b**) How many milliliters of 0.125 M H_2SO_4 are needed to neutralize 0.200 g of NaOH? (**c**) If 55.8 mL of a $BaCl_2$ solution is needed to precipitate all the sulfate ion in a 752-mg sample of Na_2SO_4, what is the molarity of the $BaCl_2$ solution? (**d**) If 42.7 mL of 0.208 M HCl solution is needed to neutralize a solution of $Ca(OH)_2$, how many grams of $Ca(OH)_2$ must be in the solution?

4.83 Some sulfuric acid is spilled on a lab bench. You can neutralize the acid by sprinkling sodium bicarbonate on it and then mopping up the resulting solution. The sodium bicarbonate reacts with sulfuric acid according to:

$$2\,NaHCO_3(s) + H_2SO_4(aq) \longrightarrow Na_2SO_4(aq) + 2\,H_2O(l) + 2\,CO_2(g)$$

Sodium bicarbonate is added until the fizzing due to the formation of $CO_2(g)$ stops. If 27 mL of 6.0 M H_2SO_4 was spilled, what is the minimum mass of $NaHCO_3$ that must be added to the spill to neutralize the acid?

4.84 The distinctive odor of vinegar is due to acetic acid, CH_3COOH, which reacts with sodium hydroxide according to:

$$CH_3COOH(aq) + NaOH(aq) \longrightarrow H_2O(l) + NaCH_3COO(aq)$$

If 3.45 mL of vinegar needs 42.5 mL of 0.115 M NaOH to reach the equivalence point in a titration, how many grams of acetic acid are in a 1.00-qt sample of this vinegar?

4.85 A 4.36-g sample of an unknown alkali metal hydroxide is dissolved in 100.0 mL of water. An acid–base indicator is added, and the resulting solution is titrated with 2.50 M HCl(aq) solution. The indicator changes color, signaling that the equivalence point has been reached, after 17.0 mL of the hydrochloric acid solution has been added. (**a**) What is the molar mass of the metal hydroxide? (**b**) What is the identity of the alkali metal cation: Li^+, Na^+, K^+, Rb^+, or Cs^+?

4.86 An 8.65-g sample of an unknown group 2A metal hydroxide is dissolved in 85.0 mL of water. An acid–base indicator is added and the resulting solution is titrated with 2.50 M HCl(aq) solution. The indicator changes color, signaling that the equivalence point has been reached, after 56.9 mL of the hydrochloric acid solution has been added. (**a**) What is the molar mass of the metal hydroxide? (**b**) What is the identity of the metal cation: Ca^{2+}, Sr^{2+}, or Ba^{2+}?

4.87 A solution of 100.0 mL of 0.200 M KOH is mixed with a solution of 200.0 mL of 0.150 M $NiSO_4$. (**a**) Write the balanced chemical equation for the reaction that occurs. (**b**) What precipitate forms? (**c**) What is the limiting reactant? (**d**) How many grams of this precipitate form? (**e**) What is the concentration of each ion that remains in solution?

4.88 A solution is made by mixing 15.0 g of $Sr(OH)_2$ and 55.0 mL of 0.200 M HNO_3. (**a**) Write a balanced equation for the reaction that occurs between the solutes. (**b**) Calculate the concentration of each ion remaining in solution. (**c**) Is the resulting solution acidic or basic?

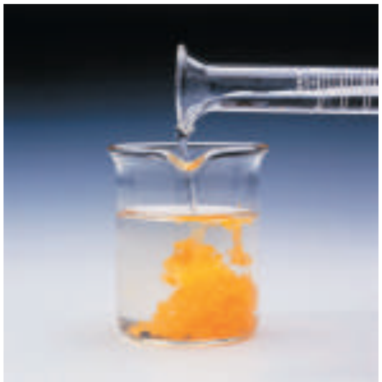
4.89 A 0.5895-g sample of impure magnesium hydroxide is dissolved in 100.0 mL of 0.2050 M HCl solution. The excess acid then needs 19.85 mL of 0.1020 M NaOH for neutralization. Calculate the percentage by mass of magnesium hydroxide in the sample, assuming that it is the only substance reacting with the HCl solution.

4.90 A 1.248-g sample of limestone rock is pulverized and then treated with 30.00 mL of 1.035 M HCl solution. The excess acid then requires 11.56 mL of 1.010 M NaOH for neutralization. Calculate the percentage by mass of calcium carbonate in the rock, assuming that it is the only substance reacting with the HCl solution.

Additional Exercises

4.91 Uranium hexafluoride, UF_6, is processed to produce fuel for nuclear reactors and nuclear weapons. UF_6 is made from the reaction of elemental uranium with ClF_3, which also produces Cl_2 as a by-product. (**a**) Write the balanced molecular equation for the conversion of U and ClF_3 into UF_6 and Cl_2. (**b**) Is this a metathesis reaction? (**c**) Is this a redox reaction?

4.92 The accompanying photo shows the reaction between a solution of $Cd(NO_3)_2$ and one of Na_2S. (**a**) What is the identity of the precipitate? (**b**) What ions remain in solution? (**c**) Write the net ionic equation for the reaction. (**d**) Is this a redox reaction?



4.93 Suppose you have a solution that might contain any or all of the following cations: Ni^{2+}, Ag^+, Sr^{2+}, and Mn^{2+}. Addition of HCl solution causes a precipitate to form. After filtering off the precipitate, H_2SO_4 solution is added to the resulting solution and another precipitate forms. This is filtered off, and a solution of NaOH is added to the resulting solution. No precipitate is observed. Which ions are present in each of the precipitates? Which of the four ions listed above must be absent from the original solution?

4.94 You choose to investigate some of the solubility guidelines for two ions not listed in Table 4.1, the chromate ion (CrO_4^{2-}) and the oxalate ion ($C_2O_4^{2-}$). You are given 0.01 M solutions (A, B, C, D) of four water-soluble salts:

Solution	Solute	Color of Solution
A	Na_2CrO_4	Yellow
B	$(NH_4)_2C_2O_4$	Colorless
C	$AgNO_3$	Colorless
D	$CaCl_2$	Colorless

When these solutions are mixed, the following observations are made:

Experiment Number	Solutions Mixed	Result
1	A + B	No precipitate, yellow solution
2	A + C	Red precipitate forms
3	A + D	Yellow precipitate forms
4	B + C	White precipitate forms
5	B + D	White precipitate forms
6	C + D	White precipitate forms

(**a**) Write a net ionic equation for the reaction that occurs in each of the experiments. (**b**) Identify the precipitate formed, if any, in each of the experiments.

4.95 Antacids are often used to relieve pain and promote healing in the treatment of mild ulcers. Write balanced net ionic equations for the reactions between the aqueous HCl in the stomach and each of the following substances used in various antacids: (**a**) $Al(OH)_3(s)$, (**b**) $Mg(OH)_2(s)$, (**c**) $MgCO_3(s)$, (**d**) $NaAl(CO_3)(OH)_2(s)$, (**e**) $CaCO_3(s)$.

4.96 The commercial production of nitric acid involves the following chemical reactions:

$$\begin{aligned} 4\,NH_3(g) + 5\,O_2(g) &\longrightarrow 4\,NO(g) + 6\,H_2O(g) \\ 2\,NO(g) + O_2(g) &\longrightarrow 2\,NO_2(g) \\ 3\,NO_2(g) + H_2O(l) &\longrightarrow 2\,HNO_3(aq) + NO(g) \end{aligned}$$

(**a**) Which of these reactions are redox reactions? (**b**) In each redox reaction identify the element undergoing oxidation and the element undergoing reduction. (**c**) How many grams of ammonia must you start with to make 1000.0 L of a 0.150 *M* aqueous solution of nitric acid? Assume all the reactions give 100% yield.

4.97 Neurotransmitters are molecules that are released by nerve cells to other cells in our bodies, and are needed for muscle motion, thinking, feeling, and memory. Dopamine is a common neurotransmitter in the human brain and is a weak base. Its molecular weight is 153.2 g/mol. (**a**) Patients with Parkinson's disease suffer from a shortage of dopamine and may need to take it to reduce symptoms. An IV (intravenous fluid) bag is filled with a solution that contains 400.0 mg dopamine per 250.0 mL of solution. What is the concentration of dopamine in the IV bag in units of molarity? (**b**) Experiments with rats show that if rats are dosed with 3.0 mg/kg of cocaine (that is, 3.0 mg cocaine per kg of animal mass), the concentration of dopamine in their brains increases by 0.75 μM after 60 seconds. Calculate how many molecules of dopamine would be produced in a rat (average brain volume $5.00\,mm^3$) after 60 seconds of a 3.0 mg/kg dose of cocaine.

4.98 Hard water contains Ca^{2+}, Mg^{2+}, and Fe^{2+}, which interfere with the action of soap and leave an insoluble coating on the insides of containers and pipes when heated. Water softeners replace these ions with Na^+. Keep in mind that charge balance must be maintained. (**a**) If 1500 L of hard water contains 0.020 *M* Ca^{2+} and 0.0040 *M* Mg^{2+}, how many moles of Na^+ are needed to replace these ions? (**b**) If the sodium is added to the water softener in the form of NaCl, how many grams of sodium chloride are needed?

4.99 Tartaric acid, $H_2C_4H_4O_6$, has two acidic hydrogens. The acid is often present in wines, and a salt derived from the acid precipitates from solution as the wine ages. A solution containing an unknown concentration of the acid is titrated with NaOH. It requires 24.65 mL of 0.2500 *M* NaOH solution to titrate both acidic protons in 50.00 mL of the tartaric acid solution. Write a balanced net ionic equation for the neutralization reaction, and calculate the molarity of the tartaric acid solution.

4.100 (**a**) A strontium hydroxide solution is prepared by dissolving 12.50 g of $Sr(OH)_2$ in water to make 50.00 mL of solution. What is the molarity of this solution? (**b**) Next the strontium hydroxide solution prepared in part (**a**) is used to titrate a nitric acid solution of unknown concentration. Write a balanced chemical equation to represent the reaction between strontium hydroxide and nitric acid solutions. (**c**) If 23.9 mL of the strontium hydroxide solution was needed to neutralize a 37.5 mL aliquot of the nitric acid solution, what is the concentration (molarity) of the acid?

4.101 A solid sample of $Zn(OH)_2$ is added to 0.350 L of 0.500 *M* aqueous HBr. The solution that remains is still acidic. It is then titrated with 0.500 *M* NaOH solution, and it takes 88.5 mL of the NaOH solution to reach the equivalence point. What mass of $Zn(OH)_2$ was added to the HBr solution?

4.102 Suppose you have 5.00 g of powdered magnesium metal, 1.00 L of 2.00 *M* potassium nitrate solution, and 1.00 L of 2.00 *M* silver nitrate solution. (**a**) Which one of the solutions will react with the magnesium powder? (**b**) What is the net ionic equation that describes this reaction? (**c**) What volume of solution is needed to completely react with the magnesium? (**d**) What is the molarity of the Mg^{2+} ions in the resulting solution?

4.103 (**a**) By titration, 15.0 mL of 0.1008 *M* sodium hydroxide is needed to neutralize a 0.2053-g sample of a weak acid. What is the molar mass of the acid if it is monoprotic? (**b**) An elemental analysis of the acid indicates that it is composed of 5.89% H, 70.6% C, and 23.5% O by mass. What is its molecular formula?

4.104 Gold is isolated from rocks by reaction with aqueous cyanide, CN^-: $4\,Au(s) + 8\,NaCN(aq) + O_2(g) + H_2O(l) \longrightarrow 4\,Na[AuCN)_2](aq) + 4\,NaOH(aq)$ (**a**) Which atoms from which compounds are being oxidized, and which atoms from which compounds are being reduced? (**b**) The $[Au(CN)_2]^-$ ion can be converted back to Au(0) by reaction with Zn(*s*) powder. Write a balanced chemical equation for this reaction. (**c**) How many liters of a 0.200 *M* sodium cyanide solution would be needed to react with 40.0 kg of rocks that contain 2.00% by mass of gold?

4.105 A fertilizer railroad car carrying 34,300 gallons of commercial aqueous ammonia (30% ammonia by mass) tips over and spills. The density of the aqueous ammonia solution is $0.88\,g/cm^3$. What mass of citric acid, $C(OH)(COOH)(CH_2COOH)_2$ (which contains three acidic protons) is required to neutralize the spill? 1 gallon = 3.785 L.

4.106 A sample of 7.75 g of $Mg(OH)_2$ is added to 25.0 mL of 0.200 *M* HNO_3. (**a**) Write the chemical equation for the reaction that occurs. (**b**) Which is the limiting reactant in the reaction? (**c**) How many moles of $Mg(OH)_2$, HNO_3, and $Mg(NO_3)_2$ are present after the reaction is complete?

Design an Experiment

You are cleaning out a chemistry lab and find three unlabeled bottles, each containing white powder. Near these bottles are three loose labels: “Sodium sulfide,” “Sodium bicarbonate,” and “Sodium chloride.” Let’s design an experiment to figure out which label goes with which bottle.

(**a**) You could try to use the physical properties of the three solids to distinguish among them. Using an Internet resource or the *CRC Handbook of Chemistry and Physics*, look up the melting points, aqueous solubilities, or other properties of these salts. Are the differences among these properties for each salt large enough to distinguish among them? If so, design a set of experiments to distinguish each salt and therefore figure out which label goes on which bottle.

(**b**) You could use the chemical reactivity of each salt to distinguish it from the others. Which of these salts, if any, will act as an acid? A base? A strong electrolyte? Can any of these salts be easily oxidized or reduced? Can any of these salts react to produce a gas? Based on your answers to these questions, design a set of experiments to distinguish each salt and thus determine which label goes on which bottle.

THERMOCHEMISTRY

▲ **THERMITE REACTION.** The reaction between aluminum metal and iron oxide produces aluminum oxide and iron metal. It also generates enough heat to melt the iron metal formed in the reaction. The thermite reaction is a dramatic illustration of how potential energy stored in chemical bonds can be converted to heat.

With the exception of the energy from the Sun, most of the energy used in our daily lives comes from chemical reactions. The combustion of hydrocarbons, the use of batteries to power electronic devices, and the chemical reactions that provide the energy needed to sustain living organisms are examples of how chemical reactions produce energy.

In this chapter we begin to explore energy and the energy changes that accompany chemical reactions. The study of energy and its transformations is known as **thermodynamics** (Greek: *thérme-*, "heat"; *dy'namis*, "power"). This area of study began during the Industrial Revolution in order to develop the relationships among heat, work, and fuels in steam engines. Here we examine the relationships between chemical reactions and energy changes that involve heat. This portion of thermodynamics is called **thermochemistry**. We discuss additional aspects of thermodynamics in Chapter 19.

WHAT'S AHEAD

5.1 ▶ The Nature of Chemical Energy Recognize that chemical energy is a form of potential energy that arises largely from the electrostatic interactions of charged particles at the atomic level. Describe energy changes associated with chemical reactions by defining the reactants and products as the *system* and everything else in the universe as the *surroundings*.

5.2 ▶ The First Law of Thermodynamics Explore the *first law of thermodynamics*, which states that energy cannot be created or destroyed but can be transformed from one form to another or transferred between systems and surroundings. The energy possessed by a system is called its *internal energy*. Internal energy is a *state function*, a quantity whose value depends only on the current state of a system, not on how the system came to be in that state.

5.3 ▶ Enthalpy Define a state function called *enthalpy*, which is useful because the change in enthalpy measures the quantity of heat energy gained or lost by a system in a process occurring under constant pressure.

5.4 ▶ Enthalpies of Reaction Discover that the enthalpy change associated with a given chemical reaction is equal to the enthalpies of the products minus the enthalpies of the reactants. This quantity is directly proportional to the amount of reactant consumed in the reaction.

5.5 ▶ Calorimetry Describe *calorimetry*, an experimental technique used to measure heat changes in chemical processes.

5.6 ▶ Hess's Law Demonstrate that the enthalpy change for a given reaction can be calculated using appropriate enthalpy changes for related reactions. To do so, we apply *Hess's law*.

5.7 ▶ Enthalpies of Formation Establish standard values for enthalpy changes in chemical reactions, and use them to calculate enthalpy changes for reactions.

5.8 ▶ Bond Enthalpies Use average bond enthalpies to estimate gas-phase reaction enthalpies.

5.9 ▶ Foods and Fuels Describe how foods and fuels serve as sources of energy, and describe some related health and social issues.

5.1 | The Nature of Chemical Energy

Learning Objective

When you finish Section 5.1, you should be able to:

- Relate the energy changes associated with the making and breaking of chemical bonds to changes in the electrostatic potential energy that arises between charged particles.

What do we mean by chemical energy? As we learned in Section 1.4, energy is defined as the capacity to do work or transfer heat. Anyone who has sat by a fire or used a propane grill has witnessed chemical reactions that release heat [**Figure 5.1**(**a**)]. Some chemical reactions also absorb heat, such as those that occur when you cook. Chemical reactions can also do work in various ways.

To understand the use of a chemical reaction to do work, recall the definition of work from Chapter 1:

$$w = F \times d \qquad [5.1]$$

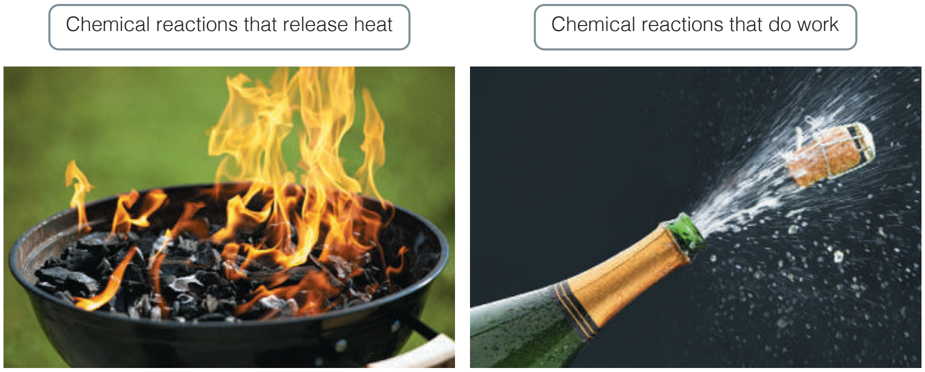
For example, the combustion reaction between gasoline and oxygen produces gases that expand and in the process do work that can be used to power an automobile. Champagne is made when yeasts use chemical reactions to ferment sugars into ethanol and carbon dioxide. By carrying out the last stages of fermentation in a corked bottle, pressure from the generated CO_2 builds up and can be used to do work when the cork is popped [Figure 5.1(**b**)]. In a battery, redox reactions produce electrical energy that can be used to do work.

All forms of energy can be classified as either kinetic or potential energy. (Section 1.4) The energy that originates from chemical reactions is associated mainly with changes in potential energy. This energy results from electrostatic interactions at the atomic level. Thus, if we are to understand the energy associated with chemical reactions, we must first understand electrostatic potential energy, which arises from the interactions between charged particles.

The electrostatic potential energy, E_{el}, associated with two charged particles is proportional to their electrical charges, Q_1 and Q_2, and is inversely proportional to the distance, d, separating them:

$$E_{el} = \frac{\kappa Q_1 Q_2}{d} \qquad [5.2]$$

where κ is a proportionality constant whose value is $8.99 \times 10^9\ \text{J-m/C}^2$.* Recall from Chapter 1 that the units used to measure energy are joules, where $1\ \text{J} = 1\ \text{kg-m}^2/\text{s}^2$. At the atomic level, the charges Q_1 and Q_2 are typically on the order of magnitude of the charge of an electron (1.60×10^{-19} C), while distances range from tenths to tens of nanometers ($1\ \text{nm} = 1 \times 10^{-9}\ \text{m}$). When we use Equation 5.2, we must also remember that Q_1 and Q_2 have signs that indicate whether the charges are positive (+) or negative (−).



Chemical reactions that release heat
Chemical reactions that do work

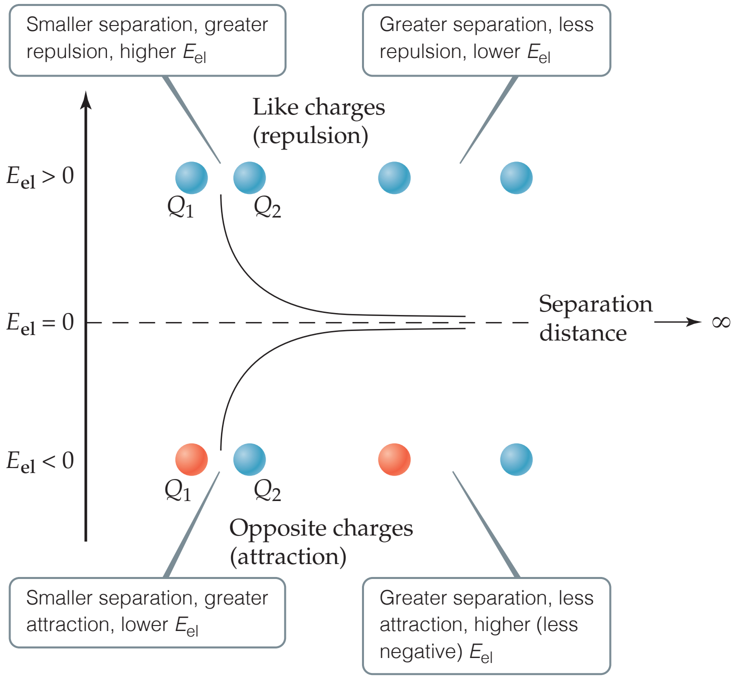
(a) **(b)**

▲ **Figure 5.1** **Chemical reactions and energy.** Energy changes in chemical reactions can be used to transfer heat or do work.

---

*We read the combined units J-m/C^2 as joule-meters per coulomb squared. You may see combinations of units such as J-m/C^2 expressed with dots separating units instead of short dashes, J·m/C^2, or with dashes and dots totally absent, J m/C^2.

Go Figure A positively charged particle and a negatively charged particle are initially far apart. What happens to their electrostatic potential energy as they are brought closer together?



Smaller separation, greater repulsion, higher E_{el}
Greater separation, less repulsion, lower E_{el}
Like charges (repulsion)
$E_{el} > 0$
Q_1
Q_2
$E_{el} = 0$
Separation distance
$\rightarrow \infty$
$E_{el} < 0$
Q_1
Q_2
Opposite charges (attraction)
Smaller separation, greater attraction, lower E_{el}
Greater separation, less attraction, higher (less negative) E_{el}

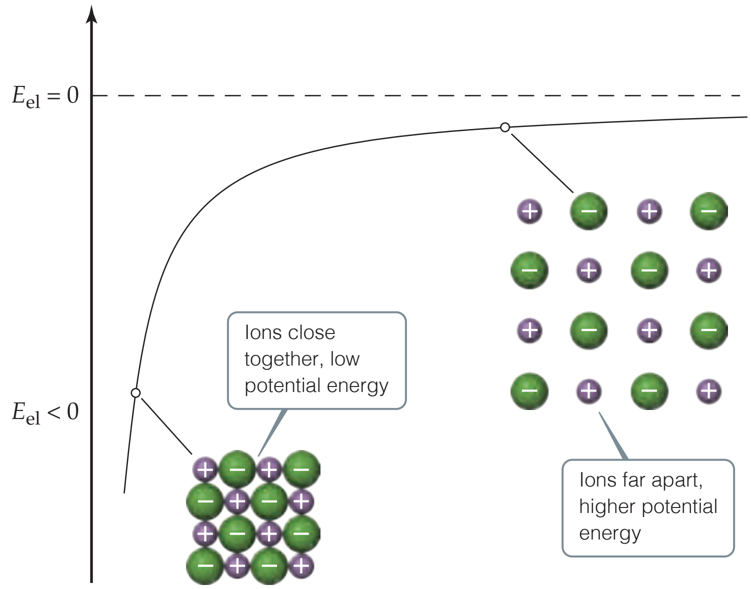
▲ **Figure 5.2 Electrostatic potential energy.** At finite separation distances, the electrostatic potential energy, E_{el}, is positive for objects with like charges and negative for objects that are oppositely charged. As the particles move farther apart, their electrostatic potential energy approaches zero.

According to Equation 5.2, electrostatic potential energy goes to zero as d becomes infinite. We define zero electrostatic potential energy as the potential energy at infinite separation of the charged particles. **Figure 5.2** illustrates how E_{el} behaves as the distance between two charges is varied. When Q_1 and Q_2 have the same sign (for example, both are positive), the two charged particles repel each other, and a repulsive force pushes them apart. To bring two positively charged objects close together, you have to do work to overcome the repulsive force that exists between the two. Upon releasing them, they move away from each other as potential energy is converted to kinetic energy. In this case, E_{el} is positive, and the potential energy decreases as the distance between particles increases. When Q_1 and Q_2 have opposite signs, the particles attract each other, and an attractive force pulls them toward each other. In this case E_{el} is negative, and the potential energy increases (becomes less negative) as the particles move apart.

To understand the relationship between electrostatic potential energy and the energy stored in chemical bonds, consider an ionic compound like NaCl. The Na^+ cations and Cl^- anions are held together by the electrostatic attraction between the oppositely charged ions. In chemistry we refer to this force as ionic bonding. We go into the details of ionic bonding in Chapter 8, but for now it is sufficient to understand that the ionic bonds that hold sodium and chloride ions together are based on the electrostatic attraction between cations and anions. To separate the ions, we must overcome, or break, the ionic bonds between Na^+ and Cl^-, increasing the potential energy, as illustrated in **Figure 5.3**. The energy to do this must come from some other source. The reverse process, where ions of opposite charge separated by a large distance are allowed to come together to form ionic bonds, lowers the potential energy and therefore releases energy. This illustrates a fundamental principle of thermochemistry:

Energy is released when chemical bonds are formed;
energy is consumed when chemical bonds are broken.

Go Figure If the ions on the right side of the figure were released and allowed to move, would they move closer together or farther apart?



$E_{el} = 0$
$E_{el} < 0$
Ions close together, low potential energy
Ions far apart, higher potential energy

▲ **Figure 5.3 Electrostatic potential energy and ionic bonding.** As the separation between ions increases, the electrostatic potential energy increases (becomes less negative). As the distance separating the ions goes toward infinity, the electrostatic potential energy goes to zero. In real compounds, repulsions between core electrons place a lower limit on how closely the ions can approach each other.

These same principles apply to molecular substances such as water, H_2O, and methane, CH_4, that do not contain cations and anions. As we explain in Chapters 8 and 9, the atoms in a molecule are held together by covalent bonds. While the link to electrostatic potential energy is less obvious, the forces that underlie covalent bonds are also electrostatic in nature. Just like ionic bonds, energy must be provided to break covalent bonds and is released when they form.

Self-Assessment Exercises

SAE 5.1 Two negative charges are separated by a distance *d*, as in the figure shown here. Which of the following statements is or are *true*?

(i) The two charges are attracted to one another.
(ii) The electrostatic potential energy of this system is positive.
(iii) As *d* increases, the electrostatic potential energy decreases.

(a) Only one of the statements is true. **(b)** i and ii are true. **(c)** i and iii are true. **(d)** ii and iii are true. **(e)** All three statements are true.

Learning Objectives

When you finish Section 5.2, you should be able to:

- Relate the first law of thermodynamics to the energy changes that accompany chemical processes.
- Relate changes in internal energy to the transfer of heat (into or out of the system) and the work done (on or by the system).
- Distinguish quantities that are state functions and from those that are not.

5.2 | The First Law of Thermodynamics

We have seen that energy comes in many different forms, and we commonly observe processes that involve conversions from one form of energy to another. Dropping a stone down a deep well converts gravitational potential energy into kinetic energy. Heating your house by reacting natural gas with oxygen converts chemical energy into heat. In both cases—and every other one you can imagine—*energy can be converted from one form to another, but it is neither created nor destroyed*. This observation, one of the most important in all of science, is known as the **first law of thermodynamics**. In this section, we explore this fundamental concept in more detail.

System and Surroundings

To apply the first law of thermodynamics quantitatively, we need to divide the universe into a finite system of interest to us, and define the energy of that system more precisely. When analyzing energy changes, we focus on a limited and well-defined part of the universe, which is called the **system**; everything else is called the **surroundings**. When we study the energy change that accompanies a chemical reaction in a laboratory, the reactants and products constitute the system. The container and everything beyond it are considered the surroundings.

Systems may be open, closed, or isolated. An *open* system is one in which matter and energy can be exchanged with the surroundings. An uncovered pot of boiling water on a stove is an open system: Heat comes into the system from the stove, and water is released to the surroundings as steam.

Closed systems are the ones we can most readily study in thermochemistry. A *closed system* can exchange energy but not matter with its surroundings. For example, consider a mixture of hydrogen gas, H_2, and oxygen gas, O_2, in a cylinder fitted with a piston (**Figure 5.4**). The system is just the hydrogen and oxygen; the cylinder, piston, and everything beyond them (including us) are the surroundings. If the gases react to form water, energy is liberated:

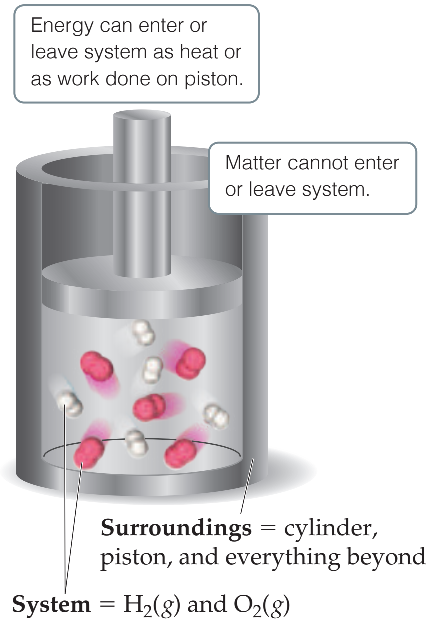
$$2\,H_2(g) + O_2(g) \longrightarrow 2\,H_2O(g) + \text{energy}$$

Although the chemical form of the hydrogen and oxygen atoms in the system is changed by this reaction, the system has not lost or gained mass, which means it has not exchanged any matter with its surroundings. However, it can exchange energy with its surroundings in the form of *work* and *heat*.

An *isolated* system is one in which neither energy nor matter can be exchanged with the surroundings. An insulated Thermos containing hot coffee approximates an isolated system. The coffee eventually cools, however, so it is not perfectly isolated.

Go Figure

If the H_2 and O_2 molecules in the cylinder react to form H_2O, will the number of molecules in the cylinder change? Will the total mass in the cylinder change?



Energy can enter or leave system as heat or as work done on piston.
Matter cannot enter or leave system.
Surroundings = cylinder, piston, and everything beyond
System = H2(g) and O2(g)

▲ **Figure 5.4** **A closed system.**

Internal Energy

The **internal energy**, E, of a system is the sum of *all* the kinetic and potential energies of the components of the system. For the system in Figure 5.4, for example, the internal energy includes not only the motions and interactions of the H_2 and O_2 molecules, but also the motions and interactions of their component nuclei and electrons. We generally do not know the numerical value of a system's internal energy. In thermodynamics, we are mainly concerned with the *change* in E (and, as we shall see, changes in other quantities as well) that accompanies a change in the system.

Imagine that we start with a system with an initial internal energy E_{initial}. The system then undergoes a change, which might involve work being done or heat being transferred. After the change, the final internal energy of the system is E_{final}. We define the *change* in internal energy, denoted ΔE (read "delta E"),* as follows:

$$\Delta E = E_{\text{final}} - E_{\text{initial}} \qquad [5.3]$$

We generally cannot determine the actual values of E_{final} and E_{initial} for any system of practical interest. Nevertheless, we can determine the value of ΔE experimentally by applying the first law of thermodynamics.

Thermodynamic quantities such as ΔE have three parts:

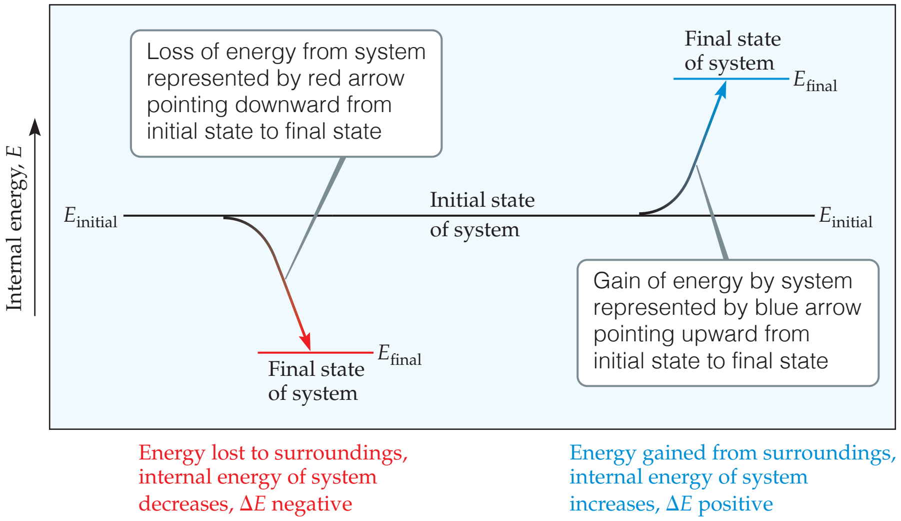
1. a number
2. a unit
3. a sign

(1) and (2) together give the magnitude of the change, while (3) gives the direction. A *positive* value of ΔE results when $E_{\text{final}} > E_{\text{initial}}$, indicating that the system has gained energy from its surroundings. A *negative* value of ΔE results when $E_{\text{final}} < E_{\text{initial}}$, indicating that the system has lost energy to its surroundings. Notice that we are taking the

---

*The symbol Δ is commonly used to denote change. For example, a change in height, h, can be represented by Δh.

Go Figure What is the value of ΔE if E_{final} equals $E_{initial}$?



Internal energy, E
Loss of energy from system represented by red arrow pointing downward from initial state to final state
Final state of system
E_final
E_initial
Initial state of system
E_initial
Gain of energy by system represented by blue arrow pointing upward from initial state to final state
E_final
Final state of system
Energy lost to surroundings, internal energy of system decreases, ΔE negative
Energy gained from surroundings, internal energy of system increases, ΔE positive

▲ **Figure 5.5** **Changes in internal energy.**

point of view of the system rather than that of the surroundings in discussing the energy changes. Because energy is conserved, any increase in the energy of the system is accompanied by a decrease in the energy of the surroundings, and vice versa. These features of energy changes are summarized in **Figure 5.5**.

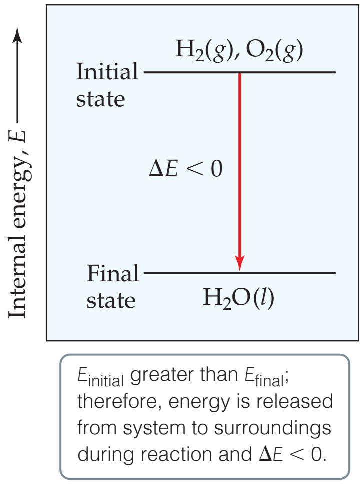
In a chemical reaction, the initial state of the system refers to the reactants and the final state refers to the products. In the reaction

$$2\,H_2(g) + O_2(g) \longrightarrow 2\,H_2O(l)$$

for instance, the initial state is $2\,H_2(g) + O_2(g)$ and the final state is $2\,H_2O(l)$. When hydrogen and oxygen form water at a given temperature, the system loses energy to the surroundings. Because energy is lost from the system, the internal energy of the products (final state) is less than that of the reactants (initial state), and ΔE for the process is negative. Thus, the *energy diagram* in **Figure 5.6** shows that the internal energy of the mixture of H_2 and O_2 is greater than that of the H_2O produced in the reaction.

Go Figure

Sketch the energy diagram representing the reaction $MgCl_2(s) \longrightarrow Mg(s) + Cl_2(g)$ knowing that the internal energy for a mixture of $Mg(s)$ and $Cl_2(g)$ is larger than that of $MgCl_2(s)$.



Internal energy, E
H2(g), O2(g)
Initial state
ΔE < 0
Final state
H2O(l)
E_initial greater than E_final; therefore, energy is released from system to surroundings during reaction and ΔE < 0.

▲ **Figure 5.6** **Energy diagram for the reaction $2\,H_2(g) + O_2(g) \longrightarrow 2\,H_2O(l)$.**

Relating ΔE to Heat and Work

As we noted in Section 5.1, a system may exchange energy with its surroundings in two general ways: as heat or as work. The internal energy of a system changes in magnitude as heat is added to or removed from the system or as work is done on or by the system. If we think of internal energy as the system's bank account of energy, then "deposits" or "withdrawals" can be made in the form of either heat or work. Deposits increase the energy of the system (positive ΔE), whereas withdrawals decrease the energy of the system (negative ΔE).

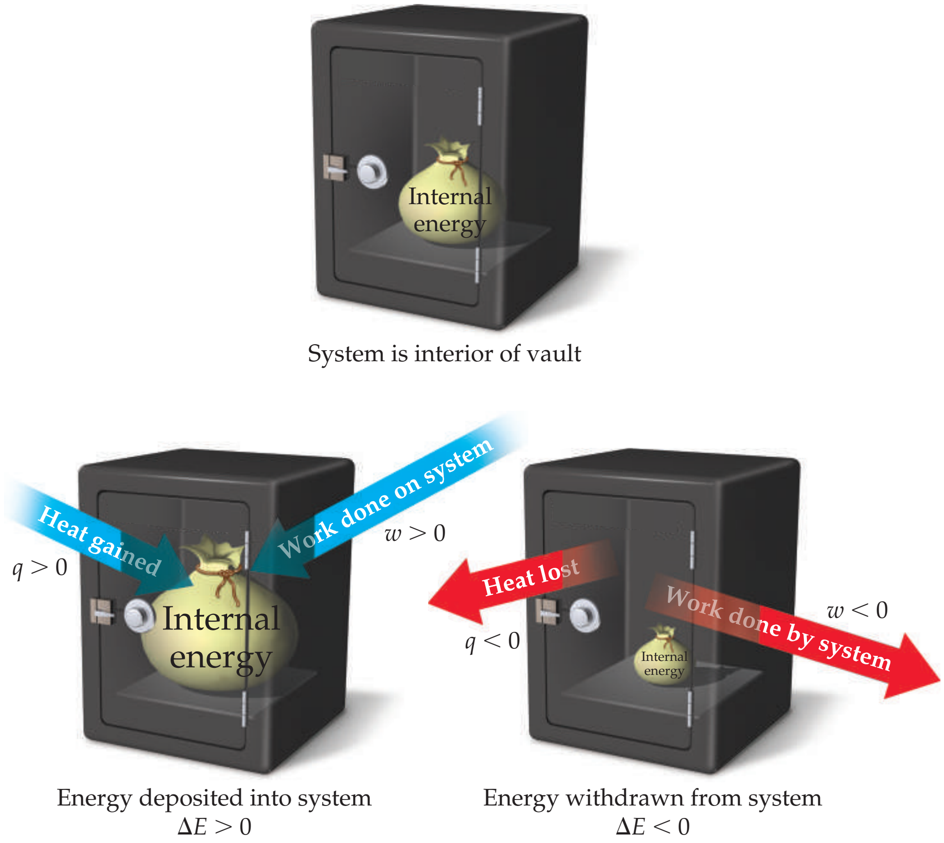
We can use these ideas to write a useful algebraic expression of the first law of thermodynamics. When a system undergoes any chemical or physical change, the accompanying change in internal energy, ΔE, is the sum of the heat added to or liberated from the system, q, and the work done on or by the system, w:

$$\Delta E = q + w \qquad [5.4]$$

When heat is added to a system or work is done on a system, its internal energy increases. Therefore, when heat is transferred to the system from the surroundings, q has a positive value. Adding heat to the system is like making a deposit to the energy account—the energy of the system increases (**Figure 5.7**). Likewise, when work is done on the system by the surroundings, w has a positive value. Conversely, both the heat lost by the system to the surroundings and the work done by the system on the surroundings have negative values; that is, they lower the internal energy of the system. They are energy withdrawals and lower the amount of energy in the system's account.

Go Figure

Suppose a system receives a “deposit” of 50 J of work from the surroundings and loses a “withdrawal” of 85 J of heat to the surroundings. What are the magnitude and the sign of ΔE for this process?



Internal energy
System is interior of vault
Heat gained
$q > 0$
Work done on system
$w > 0$
Internal energy
Heat lost
$q < 0$
Work done by system
$w < 0$
Internal energy
Energy deposited into system
$\Delta E > 0$
Energy withdrawn from system
$\Delta E < 0$

▲ **Figure 5.7** **Sign conventions for heat and work.** Heat, q, transferred into a system and work, w, done on a system are both positive quantities, corresponding to “deposits” of internal energy into the system. Conversely, heat transferred out of a system to the surroundings and work done by the system on the surroundings are both “withdrawals” of internal energy from the system.

The sign conventions for q, w, and ΔE are summarized in **Table 5.1**. Notice that any energy entering the system as either heat or work carries a positive sign.

TABLE 5.1 **Sign Conventions for q, w, and ΔE**

For q	+ means system *gains* heat from surroundings	– means system *loses* heat to surroundings
For w	+ means work done *on* system by surroundings	– means work done *by* system on surroundings
For ΔE	+ means *net gain* of energy by system	– means *net loss* of energy by system

Sample Exercise 5.1
Relating Heat and Work to Changes of Internal Energy

Gases A(g) and B(g) are confined in a cylinder-and-piston arrangement like the one shown in Figure 5.4 and react to form a solid product C(s): $A(g) + B(g) \longrightarrow C(s)$. As the reaction occurs, the system loses 1150 J of heat to the surroundings. The piston moves downward as the gases react to form a solid. As the volume of the gas decreases under the constant pressure of the atmosphere, the surroundings do 480 J of work on the system. What is the change in the internal energy of the system?

SOLUTION

Analyze The question asks us to determine ΔE, given information about q and w.

Plan Use Table 5.1 to determine the signs of q and w, and then use Equation 5.4, $\Delta E = q + w$, to calculate ΔE.

Continued

Solve Heat is transferred from the system to the surroundings, and work is done on the system by the surroundings, so q is negative and w is positive: $q = -1150\,\text{J}$ and $w = 480\,\text{J}$. Thus,

$$\Delta E = q + w = (-1150\,\text{J}) + (480\,\text{J}) = -670\,\text{J}$$

The negative value of ΔE tells us that a net quantity of 670 J of energy has been transferred from the system to the surroundings.

Comment You can think of this change as a decrease of 670 J in the net value of the system's energy bank account (hence, the negative sign); 1150 J is withdrawn in the form of heat, while 480 J is deposited in the form of work. Notice that as the volume of the gases decreases, work is being done *on* the system *by* the surroundings, resulting in a deposit of energy.

▶ Practice Exercise

Calculate the change in the internal energy for a process in which a system absorbs 140 J of heat from the surroundings and does 85 J of work on the surroundings.

Endothermic and Exothermic Processes

Because transfer of heat to and from the system is central to our discussion in this chapter, we have some special terminology to indicate the direction of transfer. When a process occurs in which the system absorbs heat, the process is called **endothermic** (*endo-* means "into"). During an endothermic process, such as the melting of ice, heat flows *into* the system from its surroundings [**Figure 5.8**(**a**)]. If we, as part of the surroundings, touch a container in which ice is melting, the container feels cold to us because heat has passed from our hand to the container.

A process in which the system loses heat is called **exothermic** (*exo-* means "out of"). During an exothermic process, such as the combustion of gasoline, heat *exits* or flows *out* of the system into the surroundings [Figure 5.8(**b**)].

State Functions

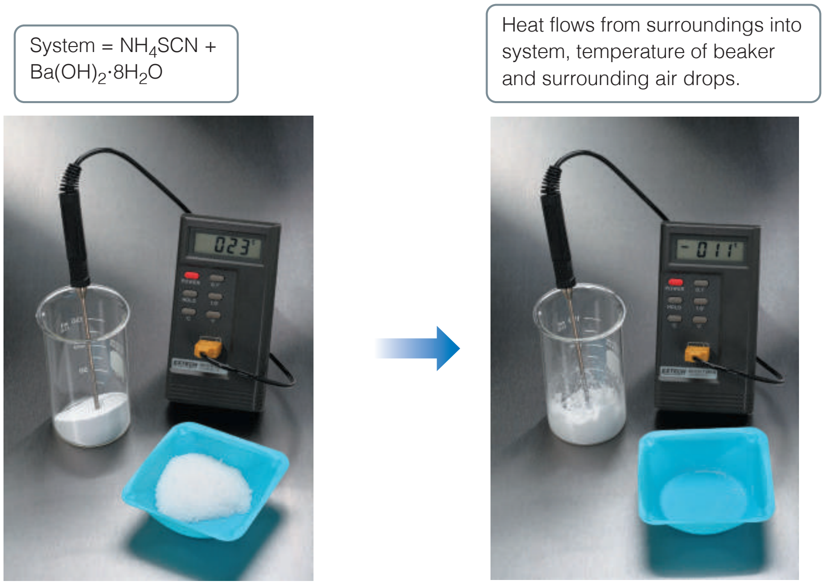
Although we usually have no way of knowing the precise value of the internal energy of a system, E, it does have a fixed value for a given set of conditions. The conditions that influence internal energy include the temperature and pressure. Furthermore, the internal energy of a system is proportional to the total quantity of matter in the system because energy is an extensive property. (Section 1.3)

Suppose we define our system as 50 g of water at 25°C (**Figure 5.9**). The system could have reached this state by cooling 50 g of water from 100 to 25°C or by melting 50 g of ice and subsequently warming the water to 25°C. The internal energy of the water at 25°C is the same in either case. Internal energy is an example of a **state function**, that is, a property of a system that is determined by specifying the system's condition or state (in terms of temperature, pressure, and so forth). *The value of a state function depends only on the present state of the system, not on the path the system took to reach that state*. Because E is a state function, ΔE depends only on the initial and final states of the system, not on how the change occurs.

An analogy may help you understand the difference between quantities that are state functions and those that are not. Suppose you drive from Chicago, which is 596 ft above sea level, to Denver, which is 5280 ft above sea level. No matter which route you take, the altitude change is 4684 ft. The distance you travel, however, depends on your route. Altitude is analogous to a state function because the change in altitude is independent of the path taken. Distance traveled is not a state function.

Because E is a state function, the change in internal energy, ΔE, does not depend on the path taken between the initial and final states of the system. However, q and w are *not* state functions; their values depend on the path taken from the initial state to the final state. Because $\Delta E = q + w$, the sum of q and w does not depend on the path, even though q and w are not state functions. Thus, if changing the path by which a system goes from an initial state to a final state increases the value of q, that path change will also decrease the value of w by exactly the same amount. The result is that ΔE is the same for the two paths.

We can illustrate this principle using a flashlight battery as our system. As the battery is discharged, its internal energy decreases as the energy stored in the battery is

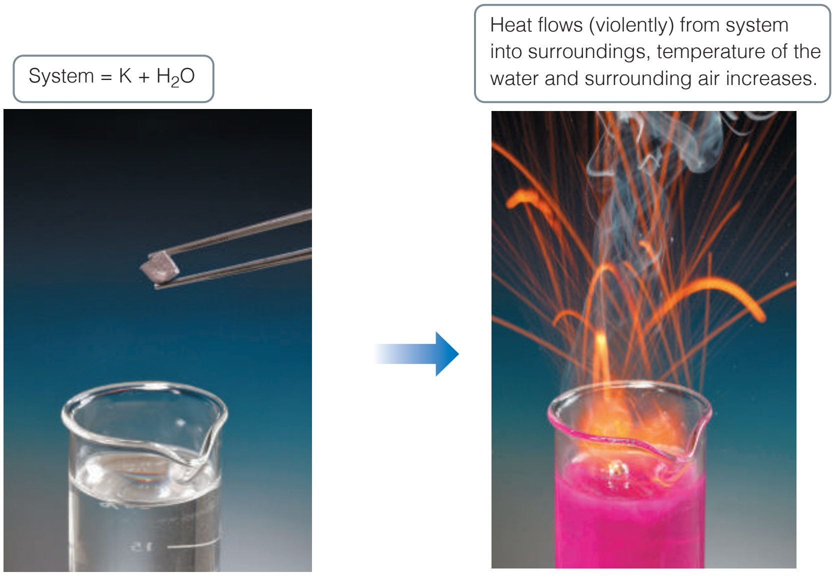


System = NH_4SCN + $Ba(OH)_2 \cdot 8H_2O$

Heat flows from surroundings into system, temperature of beaker and surrounding air drops.

(a) $Ba(OH)_2 \cdot 8H_2O + 2\ NH_4SCN \longrightarrow Ba(SCN)_2 + 2\ NH_3 + 10\ H_2O$

An endothermic reaction



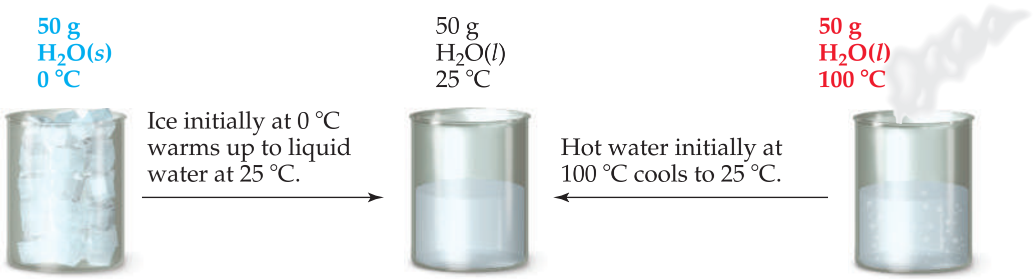
System = K + H_2O

Heat flows (violently) from system into surroundings, temperature of the water and surrounding air increases.

(b) $2\ K + 2\ H_2O \longrightarrow 2\ KOH + H_2$

An exothermic reaction

◀ **Figure 5.8** **Endothermic and exothermic reactions.** In both instances, the system is defined as the reactants and products, while surroundings are the containers and everything else in the universe (including the temperature probe in the top reaction).



Ice initially at 0 °C warms up to liquid water at 25 °C.

Hot water initially at 100 °C cools to 25 °C.

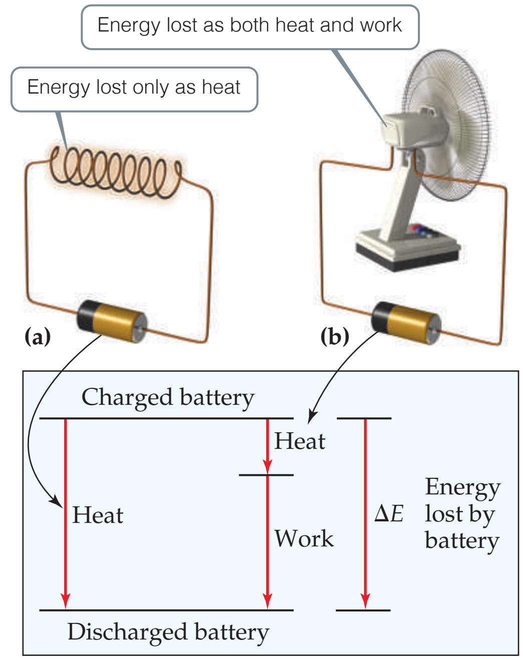
Internal energy, *E*, of the water at 25 °C is the same regardless of the path taken to reach that state.

◀ **Figure 5.9** **Internal energy, *E*, is a state function.** Any state function depends only on the present state of the system and not on the path by which the system arrived at that state.

released to the surroundings. In **Figure 5.10**, we consider two possible ways of discharging the battery. In Figure 5.10(a), a wire shorts out the battery, and no work is accomplished because nothing is moved against a force. All the energy lost from the battery is in the form of heat. (The wire gets warmer and releases heat to the surroundings.) In Figure 5.10(b), the battery is used to make a motor turn and the discharge produces work. Some heat is released, but not as much as when the battery is shorted out. The magnitudes of q and w must be different for these two cases. If the initial and final states of the battery are identical in the two cases, however, then $\Delta E = q + w$ must be the same in both cases because E is a state function. *Remember: ΔE depends only on the initial and final states of the system, not on the specific path taken from the initial state to the final state.*

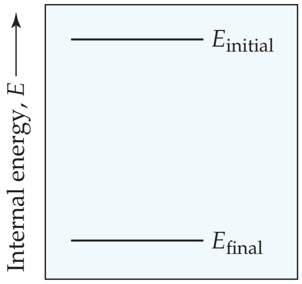
Go Figure

If the battery is defined as the system, what is the sign on w in part (**b**)?

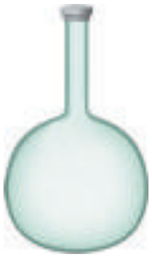


▲ **Figure 5.10 Internal energy is a state function, but heat and work are not.** (**a**) A battery shorted out by a wire loses energy to the surroundings only as heat; no work is performed. (**b**) A battery discharged through a motor loses energy as work (to make the fan turn) and also loses some energy as heat. The value of ΔE is the same for both processes, even though the values of q and w in (a) are different from those in (b).

Self-Assessment Exercises



SAE 5.2 The internal energy for the initial and final states of a system are shown in the figure. Which of the following statements is *true*? (**a**) Heat must have been added to the system. (**b**) Work must have been done on the system. (**c**) The internal energy of the final state is greater than that of the initial state. (**d**) $\Delta E < 0$.



SAE 5.3 Consider a system consisting of a gas enclosed in a stoppered flask, as shown in the accompanying figure. The flask is initially in an ice bath at $T = 0\,°C$. It is then placed in a bath of boiling water at $T = 100\,°C$. Which of the following statements is or are *true*?

(**i**) The gas in the flask is a closed system.
(**ii**) $q > 0$ for this process.
(**iii**) $\Delta E > 0$ for this process.

(**a**) Only one of the statements is true. (**b**) i and ii are true. (**c**) i and iii are true. (**d**) ii and iii are true. (**e**) All three statements are true.

SAE 5.4 While training for the Tour de France, Henri and Jacques have a race from their town to the top of a nearby mountain. Henri took a longer route, while Jacques took a more direct but steeper route. They start and finish at the same places. How many of the following quantities are state functions?

(**i**) The elevation change that Henri experienced
(**ii**) The distance that Jacques traveled
(**iii**) The time it took for Henri to complete his route
(**iv**) The amount of work that Jacques expended during his route
(**v**) The change in temperature between the town and the top of the mountain

(**a**) 1 (**b**) 2 (**c**) 3 (**d**) 4 (**e**) 5

5.3 | Enthalpy

Learning Objectives

When you finish Section 5.3, you should be able to:

- Relate the thermodynamic quantity called enthalpy to the internal energy (E), pressure (P), and volume (V) of a system.
- Define pressure–volume ($P - V$) work and calculate the magnitude and sign of $P - V$ work for a process that occurs at constant pressure.
- Interpret the sign of ΔH with respect to whether a process is endothermic or exothermic.

Many of the chemical and physical changes that occur around us, including most of the experiments you will do in the laboratory portion of your course, occur under the essentially constant pressure of Earth's atmosphere.* These changes can result in the release or absorption of heat and can be accompanied by work done by or on the system. In exploring these changes, it is useful to have a state function that relates mainly to heat flow. Under conditions of constant pressure, a thermodynamic quantity called *enthalpy* (from the Greek *enthalpein*, "to warm") provides such a function.

Enthalpy, which we denote by the symbol H, is defined as the internal energy plus the product of the *pressure*, P, and *volume*, V, of the system:

$$H = E + PV \qquad [5.5]$$

Like internal energy E, both P and V are state functions—they depend only on the current state of the system and not on the path taken to reach that state. Because energy, pressure, and volume are all state functions, enthalpy is also a state function.

---

*You may be familiar with the notion of atmospheric pressure from a previous course in chemistry. We discuss it in detail in Chapter 10. Here we need realize only that the atmosphere exerts a nearly constant pressure on the surface of Earth.

Pressure–Volume Work

To better understand the significance of enthalpy, recall from Equation 5.4 that ΔE involves not only the heat q added to or removed from the system but also the work w done by or on the system. Most commonly, the only kind of work produced by chemical or physical changes open to the atmosphere is the mechanical work associated with a change in volume. For example, consider the reaction of zinc metal with hydrochloric acid solution:

$$Zn(s) + 2\,H^{+}(aq) \rightarrow Zn^{2+}(aq) + H_2(g) \qquad [5.6]$$

When this reaction is run at constant pressure in the apparatus illustrated in **Figure 5.11**, the piston moves up or down to maintain a constant pressure in the vessel. If we assume for simplicity that the piston has no mass, the pressure in the apparatus is the same as atmospheric pressure. As the reaction proceeds, H_2 gas forms, and the piston rises. The gas within the flask is thus doing work on the surroundings by lifting the piston against the force of atmospheric pressure.

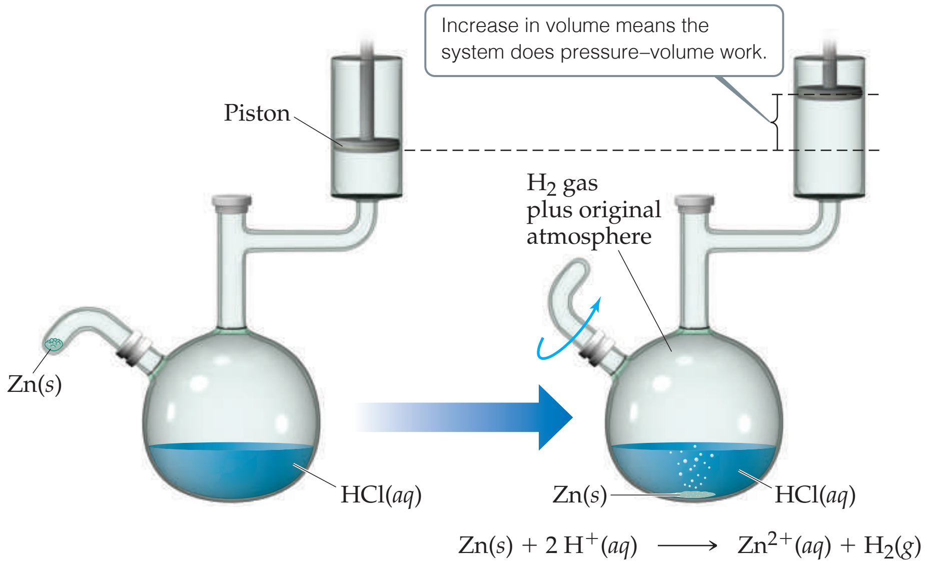
The work involved in the expansion or compression of gases is called **pressure–volume work** (P–V work). When the external pressure is constant in a process, as in our preceding example, the sign and magnitude of the pressure–volume work are given by

$$w = -P\Delta V \qquad [5.7]$$

where P is the external pressure and $\Delta V = V_{\text{final}} - V_{\text{initial}}$ is the change in volume of the system. The pressure P is always either a positive number or zero. If the volume of the system expands, then ΔV is positive as well. The negative sign in Equation 5.7 is necessary to conform to the sign convention for w (Table 5.1). When a gas expands, the system does work on the surroundings, as indicated by a negative value of w. On the other hand, if the gas is compressed, ΔV is negative (the volume decreases), and w is therefore positive according to Equation 5.7, meaning work is done on the system by the surroundings. The box "A Closer Look: Energy, Enthalpy, and P–V Work" discusses pressure–volume work in detail, but all you need to keep in mind for now is Equation 5.7, which applies to processes occurring at constant external pressure.

The units of work obtained by using Equation 5.7 will be those of pressure (usually atm) multiplied by those of volume (usually L). To express the work in the more familiar unit of joules, we use the conversion factor 1 L-atm = 101.3 J.

Go Figure If we define the system as the reactants and products, is w greater than zero or less than zero?



Increase in volume means the system does pressure–volume work.

Sample Exercise 5.2

Calculating Pressure–Volume Work

A fuel is burned in a cylinder equipped with a piston. The initial volume of the cylinder is 0.250 L, and the final volume is 0.980 L. If the piston expands against a constant pressure of 1.35 atm, how much work (in J) is done? (1 L-atm = 101.3 J)

SOLUTION

Analyze We are given an initial volume and a final volume from which we can calculate ΔV. We are also given the pressure, P. We are asked to calculate work, w.

Plan Equation 5.7, $w = -P\Delta V$, allows us to calculate the work done by the system from the given information.

Solve The volume change is

$$\Delta V = V_{\text{final}} - V_{\text{initial}} = 0.980\ \text{L} - 0.250\ \text{L} = 0.730\ \text{L}$$

Thus, the quantity of work is

$$w = -P\Delta V = -(1.35\ \text{atm})(0.730\ \text{L}) = -0.986\ \text{L-atm}$$

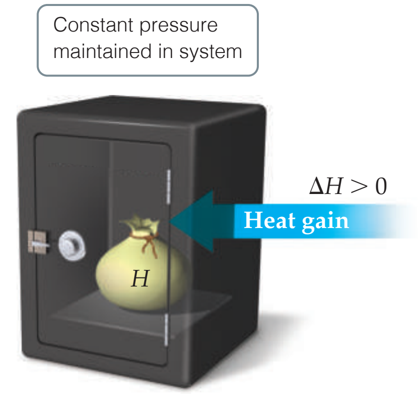
Converting L-atm to J, we have

$$(-0.986\ \cancel{\text{L-atm}})\left(\frac{101.3\ \text{J}}{1\ \cancel{\text{L-atm}}}\right) = -99.9\ \text{J}$$

Check The significant figures are correct (3), and the units are the requested ones for energy (J). The negative sign is consistent with an expanding gas doing work on its surroundings.

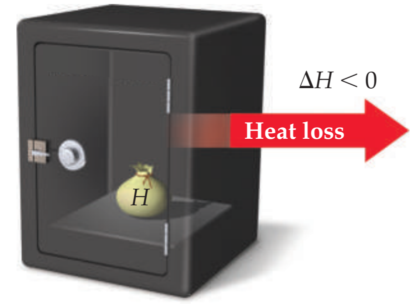
▶ Practice Exercise

Calculate the work, in J, if the volume of a system contracts from 1.55 to 0.85 L at a constant pressure of 0.985 atm.



Constant pressure maintained in system
ΔH > 0
Heat gain
H

(a) An endothermic reaction



(b) An exothermic reaction

ΔH is amount of heat that flows into or out of system under constant pressure.

▲ **Figure 5.12 Endothermic and exothermic processes.** (**a**) An endothermic process ($\Delta H > 0$) deposits heat into the system. (**b**) An exothermic process ($\Delta H < 0$) withdraws heat from the system.

Enthalpy Change and Heat

Now let's find out what is so special about enthalpy. When a change occurs at constant pressure, the change in enthalpy, ΔH, is given by the relationship

$$\begin{aligned} \Delta H &= \Delta(E + PV) \\ &= \Delta E + P\Delta V \quad \text{(constant pressure)} \end{aligned} \qquad [5.8]$$

That is, the change in enthalpy equals the change in internal energy plus the product of the constant pressure and the change in volume.

Recall that $\Delta E = q + w$ (Equation 5.4) and that the work involved in the expansion or compression of a gas is $w = -P\Delta V$ (at constant pressure). Substituting $-w$ for $P\Delta V$ and $q + w$ for ΔE into Equation 5.8, we have

$$\Delta H = \Delta E + P\Delta V = (q_P + w) - w = q_P \qquad [5.9]$$

The subscript P on q indicates that the process occurs at constant pressure. Thus, the equations show:

The change in enthalpy equals the heat q_P gained or lost by the system at constant pressure.

Because we can either measure or calculate q_P and because so many physical and chemical changes of interest to us occur at constant pressure, enthalpy is a more useful function for most reactions than is internal energy. In addition, for most common reactions, such as those you will do in lab, the difference in ΔH and ΔE is small because $P\Delta V$ is small compared to the heat involved.

When ΔH is positive (that is, when q_P is positive), the system has gained heat from the surroundings (Table 5.1), which means the process is endothermic. When ΔH is negative, the system has released heat to the surroundings, which means the process is exothermic. **Figure 5.12** continues the bank analogy of Figure 5.7. That is, under constant pressure, an endothermic process deposits energy in the system in the form of heat, whereas an exothermic process withdraws energy in the form of heat.

Because H is a state function, ΔH (which equals q_P) depends only on the initial and final states of the system, not on how the change occurs. At first glance this statement might seem to contradict our discussion in Section 5.2, in which we said that q is *not* a state function. There is no contradiction, however, because the relationship between ΔH and q_P requires that a specific path is taken between the initial and final states—namely, that only P–V work is involved and that the pressure is constant.

Sample Exercise 5.3

Determining the Sign of ΔH

Indicate the sign of the enthalpy change, ΔH, in the following processes carried out under atmospheric pressure, and indicate whether each process is endothermic or exothermic: (**a**) An ice cube melts; (**b**) 1 g of butane (C_4H_{10}) is completely combusted to CO_2 and H_2O.

SOLUTION

Analyze Our goal is to determine whether ΔH is positive or negative for each process. Because each process occurs at constant pressure, the enthalpy change equals the quantity of heat absorbed or released, $\Delta H = q_P$.

Plan We must predict whether heat is absorbed or released by the system in each process. Processes in which heat is absorbed are endothermic and have a positive sign for ΔH; those in which heat is released are exothermic and have a negative sign for ΔH.

Solve In (a) the water that makes up the ice cube is the system. The ice cube absorbs heat from the surroundings as it melts, so ΔH is positive and the process is endothermic. In (b) the system is the 1 g of butane and the oxygen required to combust it. The combustion of butane in oxygen gives off heat, so ΔH is negative and the process is exothermic.

Practice Exercise

Molten gold poured into a mold solidifies at atmospheric pressure. With the gold defined as the system, is the solidification an exothermic or endothermic process?

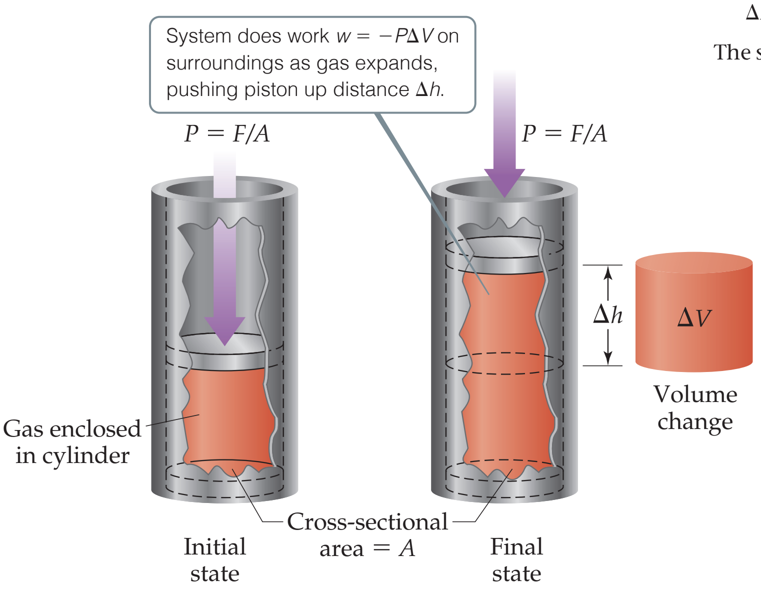
A CLOSER LOOK Energy, Enthalpy, and *P–V* Work

In chemistry we are interested mainly in two types of work: electrical work and mechanical work done by expanding gases. We focus here on the latter, called pressure–volume, or *P–V*, work. Expanding gases in the cylinder of an automobile engine do *P–V* work on the piston; this work eventually turns the wheels. Expanding gases from an open reaction vessel do *P–V* work on the atmosphere. This work accomplishes nothing in a practical sense, but when monitoring energy changes in a system, we must keep track of all work, useful or not.

Let's consider a gas confined to a cylinder with a movable piston of cross-sectional area A (**Figure 5.13**). A downward force F acts on the piston. The pressure, P, on the gas is the force per area: $P = F/A$. We assume that the piston is massless and that the only pressure acting on it is the *atmospheric pressure* that is due to Earth's atmosphere, which we assume to be constant.

Suppose the gas expands and the piston moves a distance Δh. From Equation 5.1, the magnitude of the work done by the system is

$$\text{Magnitude of work} = \text{force} \times \text{distance} = F \times \Delta h \qquad [5.10]$$



System does work $w = -P\Delta V$ on surroundings as gas expands, pushing piston up distance Δh.
$P = F/A$
$P = F/A$
Δh
ΔV
Volume change
Gas enclosed in cylinder
Cross-sectional area = A
Initial state
Final state

▲ **Figure 5.13 Pressure–volume work.** The amount of work done by the system on the surroundings is $w = -P\Delta V$.

We can rearrange the definition of pressure, $P = F/A$, to $F = P \times A$. The volume change, ΔV, resulting from the movement of the piston is the product of the cross-sectional area of the piston and the distance it moves: $\Delta V = A \times \Delta h$. Substituting into Equation 5.10 gives

$$\begin{aligned}\text{Magnitude of work} &= F \times \Delta h = P \times A \times \Delta h \\ &= P \times \Delta V\end{aligned}$$

Because the system (the confined gas) does work on the surroundings, the work is a negative quantity:

$$w = -P\Delta V \qquad [5.11]$$

Now, if *P–V* work is the only work that can be done, we can substitute Equation 5.11 into Equation 5.4 to give

$$\Delta E = q + w = q - P\Delta V \qquad [5.12]$$

When a reaction is carried out in a constant-volume container ($\Delta V = 0$), the heat transferred equals the change in internal energy:

$$\Delta E = q - P\Delta V = q - P(0) = q_V \quad \text{(constant volume)} \qquad [5.13]$$

The subscript V indicates that the volume is constant.

Most reactions are run under constant pressure, so Equation 5.12 becomes

$$\Delta E = q_P - P\Delta V$$

$$q_P = \Delta E + P\Delta V \quad \text{(constant pressure)} \qquad [5.14]$$

We see from Equation 5.8 that the right side of Equation 5.14 is the enthalpy change under constant-pressure conditions. Thus, $\Delta H = q_P$, as we saw in Equation 5.9.

In summary, the change in internal energy is equal to the heat gained or lost at constant volume, whereas the change in enthalpy is equal to the heat gained or lost at constant pressure. The difference between ΔE and ΔH is the amount of *P–V* work done by the system when the process occurs at constant pressure, $-P\Delta V$. The volume change accompanying many reactions is close to zero, which makes $P\Delta V$ small. That, in turn, makes the difference between ΔE and ΔH small. Under most circumstances, it is generally satisfactory to use ΔH as the measure of energy changes during most chemical processes.

Related Exercises: 5.35–5.38, 5.107

Self-Assessment Exercises

SAE 5.5 Which of the following statements about enthalpy is correct? (**a**) Enthalpy is a short-hand term for internal energy. (**b**) A process for which $\Delta H > 0$ is called exothermic. (**c**) Because enthalpy relates to heat, the enthalpy change for a process depends on the path taken. (**d**) For a process run under constant pressure, the enthalpy change equals the amount of heat transferred into or out of the system.

SAE 5.6 A gas is confined to a piston equipped with a cylinder at constant temperature. Under a constant pressure on the cylinder of 1.60 atm, the gas is compressed from an initial volume of 2.00 L to a final volume of 0.80 L. What are the magnitude and sign of the work done during this process, in J? (Note: 1 L-atm = 101.3 J) (**a**) 0 J (**b**) −194 J (**c**) −130 J (**d**) +130 J (**e**) +194 J

SAE 5.7 When a system that consists of a block of dry ice, $CO_2(s)$, is placed on a wooden board at room temperature and under the constant pressure of the atmosphere, it sublimes into $CO_2(g)$. This process is _____ and has a _____ value of ΔH. (**a**) endothermic, positive (**b**) endothermic, negative (**c**) exothermic, positive (**d**) exothermic, negative

5.4 | Enthalpies of Reaction

Learning Objectives

When you finish Section 5.4, you should be able to:

- Interpret the enthalpy of reaction, ΔH, using the enthalpies of the products and the reactants.
- Determine how ΔH changes when the equation for a balanced reaction is multiplied by the same number, or when the reaction is reversed.

In this section, we begin to explore one of the most common ways in which chemists use enthalpy—examining the enthalpy change that occurs during a chemical reaction.

Recall that $\Delta H = H_{\text{final}} - H_{\text{initial}}$. Hence, the enthalpy change for a chemical reaction is given by

$$\Delta H = H_{\text{products}} - H_{\text{reactants}} \qquad [5.15]$$

The enthalpy change that accompanies a reaction is called either the **enthalpy of reaction** or the *heat of reaction* and is sometimes written ΔH_{rxn}, where "rxn" is a commonly used abbreviation for "reaction."

When we give a numerical value for ΔH_{rxn}, we must specify the reaction involved. For example, when 2 mol $H_2(g)$ burn to form 2 mol $H_2O(g)$ at a constant pressure, the system releases 483.6 kJ of heat. We can summarize this information as

$$2\,H_2(g) + O_2(g) \longrightarrow 2\,H_2O(g) \qquad \Delta H = -483.6\text{ kJ} \qquad [5.16]$$

The negative sign for ΔH tells us that this reaction is exothermic. Notice that ΔH is reported at the end of the balanced equation, without explicitly specifying the amounts of chemicals involved. In such cases, *the coefficients in the balanced equation represent the number of moles of reactants and products* producing the associated enthalpy change. Balanced chemical equations that show the associated enthalpy change in this way are called *thermochemical equations*.

The exothermic nature of this reaction is also shown in the *enthalpy diagram* in Figure 5.14. Notice that the enthalpy of the reactants is greater (more positive) than the enthalpy of the products. Thus, $\Delta H = H_{\text{products}} - H_{\text{reactants}}$ is negative.

The following guidelines are helpful when using thermochemical equations and enthalpy diagrams:

1. **Enthalpy is an extensive property.** The magnitude of ΔH is proportional to the amount of reactant consumed in the process. For example, 890 kJ of heat is produced when 1 mol of CH_4 is burned in a constant-pressure system:

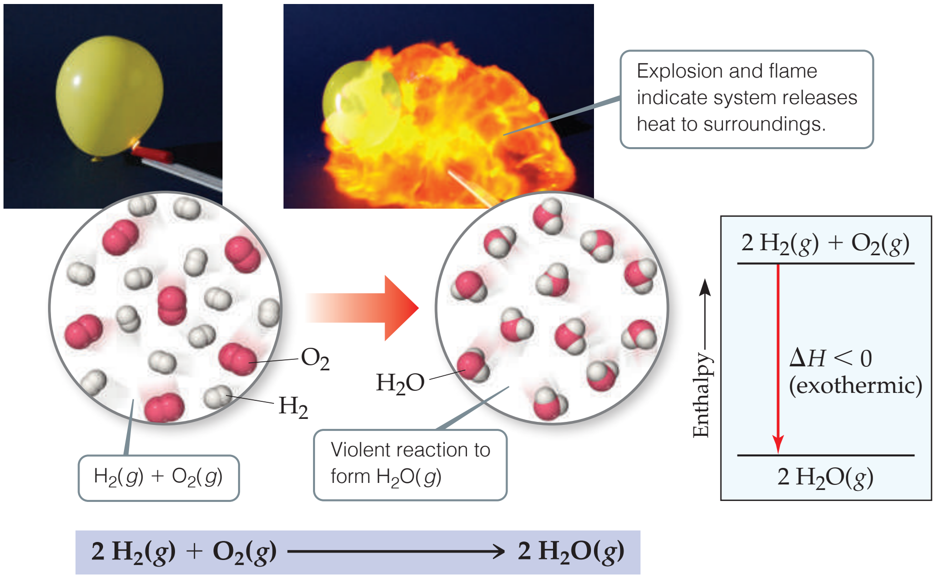
$$CH_4(g) + 2\,O_2(g) \longrightarrow CO_2(g) + 2\,H_2O(l) \qquad \Delta H = -890\text{ kJ} \qquad [5.17]$$

   Because the combustion of 1 mol of CH_4 with 2 mol of O_2 releases 890 kJ of heat, the combustion of 2 mol of CH_4 with 4 mol of O_2 releases twice as much heat, 1780 kJ. Although chemical equations are usually written with whole-number coefficients, we will see examples of thermochemical equations that utilize fractional coefficients.

2. **The enthalpy change for a reaction is equal in magnitude, but opposite in sign, to ΔH for the reverse reaction.** For example, ΔH for the reverse of Equation 5.17 is +890 kJ:

$$CO_2(g) + 2\,H_2O(l) \longrightarrow CH_4(g) + 2\,O_2(g) \qquad \Delta H = +890\text{ kJ} \qquad [5.18]$$

Go Figure If a reaction causes an explosion, what can we conclude about ΔH?



Explosion and flame indicate system releases heat to surroundings.
O_2
H_2
H_2O
$H_2(g) + O_2(g)$
Violent reaction to form $H_2O(g)$
Enthalpy
$2\,H_2(g) + O_2(g)$
$\Delta H < 0$ (exothermic)
$2\,H_2O(g)$
$2\,H_2(g) + O_2(g) \longrightarrow 2\,H_2O(g)$

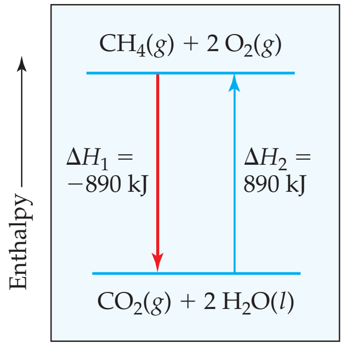
▲ **Figure 5.14** **Exothermic reaction of hydrogen with oxygen.** When a mixture of $H_2(g)$ and $O_2(g)$ is ignited to form $H_2O(g)$, the resulting explosion produces a ball of flame. Because the system releases heat to the surroundings, the reaction is exothermic, as indicated in the enthalpy diagram.

When we reverse a reaction, we reverse the roles of the products and the reactants. From Equation 5.15, reversing the products and reactants leads to the same magnitude of ΔH, but a change in sign (Figure 5.15).

3. **The enthalpy change for a reaction depends on the states of the reactants and products.** If the product in Equation 5.17 were $H_2O(g)$ instead of $H_2O(l)$, ΔH_{rxn} would be -802 kJ instead of -890 kJ. Less heat would be available for transfer to the surroundings because the enthalpy of $H_2O(g)$ is greater than that of $H_2O(l)$. One way to see this is to imagine that the product is initially liquid water. The liquid water must be converted to water vapor, and the conversion of 2 mol $H_2O(l)$ to 2 mol $H_2O(g)$ is an endothermic process that absorbs 88 kJ:

$$2\,H_2O(l) \longrightarrow 2\,H_2O(g) \qquad \Delta H = +88\text{ kJ} \qquad [5.19]$$

Thus, it is important to specify the states of the reactants and products in thermochemical equations. In addition, we will generally assume that the reactants and products are both at the same temperature, 25°C, unless otherwise indicated.



Enthalpy
$CH_4(g) + 2\,O_2(g)$
$\Delta H_1 = -890$ kJ
$\Delta H_2 = 890$ kJ
$CO_2(g) + 2\,H_2O(l)$

▲ **Figure 5.15** **ΔH for the reverse of a reaction.** Reversing a reaction changes the sign but not the magnitude of the enthalpy change: $\Delta H_2 = -\Delta H_1$.

Sample Exercise 5.4

Relating ΔH to Quantities of Reactants and Products

How much heat is released when 4.50 g of methane gas is burned in a constant-pressure system? (Use the information given in Equation 5.17.)

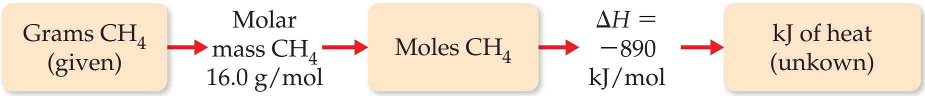
SOLUTION

Analyze Our goal is to use a thermochemical equation to calculate the heat produced when a specific amount of methane gas is combusted. According to Equation 5.17, the system releases 890 kJ when 1 mol CH_4 is burned at constant pressure.

Plan Equation 5.17 provides us with a stoichiometric conversion factor: (1 mol $CH_4 \simeq -890$ kJ). Thus, we can convert moles of CH_4 to kJ of energy. First, however, we must convert grams of CH_4 to moles of CH_4.

Solve

The conversion sequence is:



Grams CH_4 (given)
Molar mass CH_4 16.0 g/mol
Moles CH_4
$\Delta H = -890$ kJ/mol
kJ of heat (unkown)

Continued

By adding the atomic weights of C and 4 H, we have 1 mol $CH_4 = 16.0\ \text{g}\ CH_4$. We now use the appropriate conversion factors to convert grams of CH_4 to moles of CH_4 to kilojoules:

$$\text{Heat} = (4.50\ \text{g}\ \cancel{CH_4})\left(\frac{1\ \cancel{\text{mol}\ CH_4}}{16.0\ \text{g}\ \cancel{CH_4}}\right)\left(\frac{-890\ \text{kJ}}{1\ \cancel{\text{mol}\ CH_4}}\right) = -250\ \text{kJ}$$

The negative sign indicates that the system released 250 kJ into the surroundings.

Practice Exercise

Hydrogen peroxide can decompose to water and oxygen by the reaction

$$2\,H_2O_2(l) \longrightarrow 2\,H_2O(l) + O_2(g) \qquad \Delta H = -196\ \text{kJ}$$

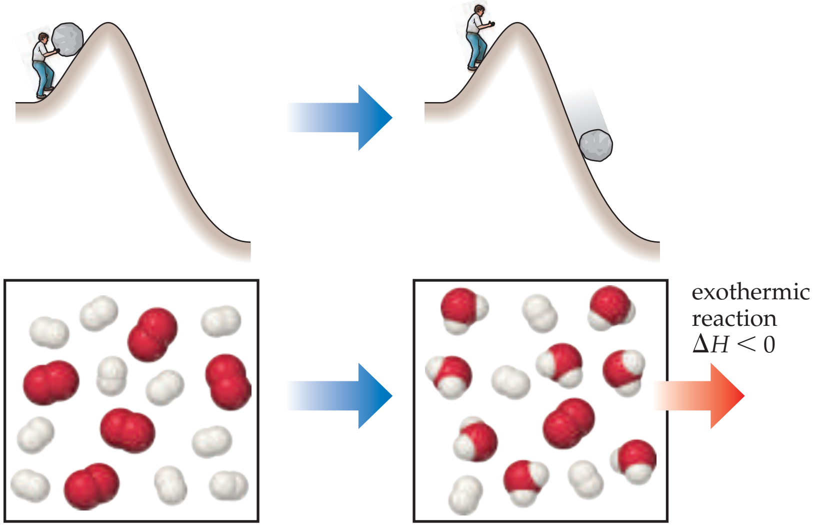
Calculate the quantity of heat released when 5.00 g of $H_2O_2(l)$ decomposes at constant pressure.

A CLOSER LOOK Using Enthalpy as a Guide

If you hold a brick in the air and let it go, you know what happens: It falls as the force of gravity pulls it toward Earth. A process that is thermodynamically favored to happen, such as a brick falling to the ground, is called a *spontaneous* process. A spontaneous process can be either fast or slow; the rate at which processes occur is not governed by thermodynamics.

Chemical processes can be thermodynamically favored, or spontaneous, too. By spontaneous, however, we do not mean that the reaction will form products without any intervention. That can be the case, but often some energy must be imparted to get the process started. Just as it is spontaneous for a rock to roll down the side of a hill once started, so too can it be spontaneous for chemical reactions to proceed once enough energy is imparted to initiate the reaction (Figure 5.16). The enthalpy change in a reaction gives one indication as to whether the reaction is likely to be spontaneous. The combustion of $H_2(g)$ and $O_2(g)$, for example, is highly exothermic:

$$H_2(g) + \tfrac{1}{2}O_2(g) \longrightarrow H_2O(g) \qquad \Delta H = -242\ \text{kJ}$$



▲ **Figure 5.16 Exothermic reactions and spontaneity.** Chemical reactions that are highly exothermic (ΔH much less than 0) usually occur spontaneously. Such reactions often need some input of energy to get started, just like it can take a push to get a boulder rolling down a hill to a spot of lower potential energy. However, once they get started, such reactions spontaneously proceed to form the products, which have lower potential energy.

Hydrogen gas and oxygen gas can exist together in a volume indefinitely without noticeable reaction occurring. Once the reaction is initiated, however, energy is rapidly transferred from the system (the reactants) to the surroundings as heat, as shown previously in Figure 5.14. The system thus loses enthalpy by transferring the heat to the surroundings. (Recall that the first law of thermodynamics tells us that the total energy of the system plus the surroundings does not change; energy is conserved.)

Enthalpy change is not the only consideration in the spontaneity of reactions, nor is it a foolproof guide. For example, even though ice melting is an endothermic process,

$$H_2O(s) \longrightarrow H_2O(l) \qquad \Delta H = +6.01\ \text{kJ}$$

it is spontaneous at temperatures above the freezing point of water (0 °C). The reverse process, water freezing, is spontaneous at temperatures below 0 °C. Thus, we know that ice at room temperature melts and that water put into a freezer at −20 °C turns into ice. Both processes are spontaneous under different conditions, even though they are the reverse of one another. In Chapter 19, we address the spontaneity of processes more fully. There we explain why a process can be spontaneous at one temperature but not at another, as is the case for the conversion of water to ice.

Despite these complicating factors, you should pay attention to the enthalpy changes in reactions. As a general observation, when the enthalpy change is large, it is the dominant factor in determining spontaneity. Thus, reactions for which ΔH is *large* (about 100 kJ or more) and *negative* tend to be spontaneous. Reactions for which ΔH is *large* and *positive* tend to be spontaneous only in the reverse direction.

Related Exercises: 5.47, 5.48

In many situations, we will find it valuable to know the sign and magnitude of the enthalpy change associated with a given chemical process. As we describe in the following sections, ΔH can be either determined directly by experiment or calculated from known enthalpy changes of other reactions.

Self-Assessment Exercises

SAE 5.8 For a hypothetical reaction $X(g) \rightarrow Y(g)$, you are told that the enthalpy of $Y(g)$ is greater than that of $X(g)$. Which of the following statements is *false*? (**a**) ΔH for the reaction is positive. (**b**) On an enthalpy diagram, the line for $Y(g)$ is below the line for $X(g)$. (**c**) The reaction is endothermic. (**d**) The enthalpies of $X(g)$ and $Y(g)$ could both have negative values.

SAE 5.9 The following is the balanced reaction and enthalpy change when one mole of carbon monoxide gas is formed from graphite and oxygen gas under constant pressure:

$$C(s) + {}^{1}/_{2}\,O_2(g) \longrightarrow CO(g) \quad \Delta H = -110.5\text{ kJ}$$

What is the enthalpy change for the following reaction:

$$2\,CO(g) \longrightarrow 2\,C(s) + O_2(g) \quad \Delta H = ?$$

(**a**) −221.0 kJ (**b**) −55.25 kJ (**c**) +55.25 kJ (**d**) +221.0 kJ (**e**) More information is needed.

SAE 5.10 Solid sodium hydroxide dissolves in water to form aqueous sodium cations and hydroxide anions:

$$NaOH(s) \longrightarrow Na^{+}(aq) + OH^{-}(aq) \quad \Delta H = -44.5\text{ kJ}$$

How much heat is released to the solution when 25.0 g of NaOH(s) is dissolved in water under constant pressure? (**a**) 1.78 kJ (**b**) 27.8 kJ (**c**) 44.5 kJ (**d**) 71.2 kJ (**e**) 1110 kJ

5.5 | Calorimetry

The value of ΔH can be determined experimentally by measuring the heat flow accompanying a reaction at constant pressure. Typically, we can determine the magnitude of the heat flow by measuring the magnitude of the temperature change the heat flow produces. The measurement of heat flow is called **calorimetry**, and the device used to measure heat flow is a **calorimeter**.

Learning Objectives

When you finish Section 5.5, you should be able to:

- Interpret heat capacity and specific heat as measures of the heat needed to change the temperature of a substance.
- Use the relationships among C_s, q, m, and ΔT to calculate one of the values given the other three.
- Describe how a constant-pressure calorimeter works and analyze the results of constant-pressure calorimetry to determine heats of reactions.
- Describe how a constant-volume calorimeter works and analyze the results of constant-volume calorimetry to determine heats of reactions.

Heat Capacity and Specific Heat

All substances get hotter as heat is added to them, but the magnitude of the temperature change produced by a given quantity of heat varies from substance to substance. The temperature change experienced by an object when it absorbs a certain amount of heat is determined by its **heat capacity**, denoted C. The heat capacity of an object is the amount of heat required to raise its temperature by 1 K (or 1 °C). The greater the heat capacity, the greater the heat required to produce a given increase in temperature.

For pure substances, the heat capacity is usually given for a specified amount of the substance. The heat capacity of one mole of a substance is called its **molar heat capacity**, C_m. The heat capacity of one gram of a substance is called its *specific heat capacity*, or merely its **specific heat**, C_s. The specific heat of a substance can be determined experimentally by measuring the temperature change, ΔT, that a known mass m of the substance undergoes when it gains or loses a specific quantity of heat q:

$$\text{Specific heat} = \frac{(\text{quantity of heat transferred})}{(\text{grams of substance}) \times (\text{temperature change})}$$

$$C_s = \frac{q}{m \times \Delta T} \qquad [5.20]$$

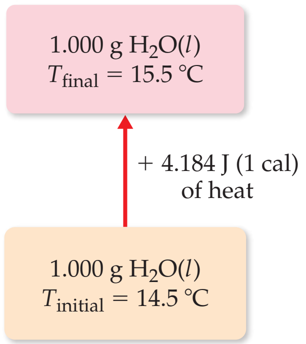
For example, 209 J is required to increase the temperature of 50.0 g of water by 1.00 K. Thus, the specific heat of water is

$$C_s = \frac{209\text{ J}}{(50.0\text{ g})(1.00\text{ K})} = 4.18\text{ J/g} - \text{K}$$

Notice how the units combine in the calculation. A temperature change in K is equal in magnitude to the temperature change in °C. (Section 1.5) Therefore, this specific heat for water can also be reported as 4.18 J/g-°C, where the unit is pronounced “Joules per gram-degree Celsius.”

Go Figure

Is the process shown in the figure endothermic or exothermic?



▲ **Figure 5.17** **The specific heat of water is 4.184 J (1 cal) at 14.5 °C.**

Because the specific heat values for a given substance can vary slightly with temperature, the temperature is often precisely specified. The 4.18 J/g-K value we use here for water, for instance, is for water initially at 14.5 °C (**Figure 5.17**). Water's specific heat at this temperature is used to define the calorie at the value given in Section 1.5: 1 cal = 4.184 J exactly.

When a sample absorbs heat (positive q), its temperature increases (positive ΔT). Rearranging Equation 5.20, we get

$$q = C_s \times m \times \Delta T \qquad [5.21]$$

Thus, we can calculate the quantity of heat a substance gains or loses by using its specific heat together with its measured mass and temperature change.

Table 5.2 lists the specific heats of several substances. Notice that the specific heat of liquid water is higher than the specific heats of the other substances listed. The high specific heat of water affects Earth's climate because it makes the temperatures of the oceans relatively resistant to change.

TABLE 5.2 Specific Heats of Some Substances at 298 K

Elements		Compounds	
Substance	**Specific Heat (J/g-K)**	**Substance**	**Specific Heat (J/g-K)**
$N_2(g)$	1.04	$H_2O(l)$	4.18
$Al(s)$	0.90	$CH_4(g)$	2.20
$Fe(s)$	0.45	$CO_2(g)$	0.84
$Hg(l)$	0.14	$CaCO_3(s)$	0.82

Sample Exercise 5.5

Relating Heat, Temperature Change, and Heat Capacity

(**a**) How much heat is needed to warm 250 g of water (about 1 cup) from 22 °C (about room temperature) to 98 °C (near its boiling point)? (**b**) What is the molar heat capacity of water?

SOLUTION

Analyze In part (**a**) we must find the quantity of heat (q) needed to warm the water, given the mass of water (m), its temperature change (ΔT), and its specific heat C_s. In part (**b**) we must calculate the molar heat capacity (heat capacity per mole, C_m) of water from its specific heat (heat capacity per gram).

Plan (**a**) Given C_s, m, and ΔT, we can calculate the quantity of heat, q, using Equation 5.21. (**b**) We can use the molar mass of water and dimensional analysis to convert from heat capacity per gram to heat capacity per mole.

Solve

(**a**) The water undergoes a temperature change of:

$$\Delta T = 98°C - 22°C = 76°C = 76\ K$$

Using Equation 5.21, we have:

$$q = C_s \times m \times \Delta T$$

$$= (4.18\ J/\cancel{g}\text{-}\cancel{K})(250\ \cancel{g})(76\ \cancel{K}) = 7.9 \times 10^4\ J$$

(**b**) The molar heat capacity is the heat capacity of one mole of substance. Using the atomic weights of hydrogen and oxygen, we have:

$$1\ mol\ H_2O = 18.0\ g\ H_2O$$

From the specific heat used in part (**a**), we have:

$$C_m = \left(4.18\ \frac{J}{\cancel{g}\text{-K}}\right)\left(\frac{18.0\ \cancel{g}}{1\ mol}\right) = 75.2\ J/mol\text{-}K$$

▶ **Practice Exercise**

(**a**) Large beds of rocks are used in some solar-heated homes to store heat. Assume that the specific heat of the rocks is 0.82 J/g-K. Calculate the quantity of heat absorbed by 50.0 kg of rocks if their temperature increases by 12.0 °C. (**b**) What temperature change would these rocks undergo if they emitted 450 kJ of heat?

Constant-Pressure Calorimetry

The techniques and equipment used in calorimetry depend on the nature of the process being studied. For many reactions, such as those occurring in solution, it is easy to control pressure so that ΔH is measured directly. A simple "coffee-cup" calorimeter (**Figure 5.18**) is often used in general chemistry laboratories to illustrate the principles of calorimetry.

Because the calorimeter is not sealed, the reaction occurs under the essentially constant pressure of the atmosphere.

Imagine adding two aqueous solutions, each containing a reactant, to a coffee-cup calorimeter. Once mixed, a reaction occurs. In this case, there is no physical boundary between the system and the surroundings. The reactants and products of the reaction are the system, and the water in which they are dissolved is part of the surroundings. (The calorimeter apparatus is also part of the surroundings.) If we assume that the calorimeter is perfectly insulated, then any heat released or absorbed by the reaction will raise or lower the temperature of the water in the solution. Thus, we measure the temperature change of the solution and assume that any changes are due to heat transferred from the reaction to the water (for an exothermic process) or transferred from the water to the reaction (for an endothermic process). In other words, by monitoring the temperature of the solution, we are seeing the flow of heat between the system (the reactants and products in the solution) and the surroundings (the water that forms the bulk of the solution).

For an exothermic reaction, heat is "lost" by the reaction and "gained" by the water in the solution, so the temperature of the solution rises. The opposite occurs for an endothermic reaction: Heat is gained by the reaction and lost by the water in the solution, so the temperature of the solution decreases. The heat gained or lost by the solution, q_{soln}, is therefore equal in magnitude but opposite in sign to the heat absorbed or released by the reaction, $q_{\text{rxn}}: q_{\text{soln}} = -q_{\text{rxn}}$. The value of q_{soln} is readily calculated from the mass of the solution, its specific heat, and the temperature change:

$$q_{\text{soln}} = (\text{specific heat of solution}) \times (\text{grams of solution}) \times \Delta T = -q_{\text{rxn}} \qquad [5.22]$$

For dilute aqueous solutions, the specific heat of the solution is nearly the same as that of pure water, so it is normally safe to assume that the specific heat of the solution is 4.18 J/g-K.

Equation 5.22 makes it possible to calculate q_{rxn} from the temperature change of the solution in which the reaction occurs. A temperature increase ($\Delta T > 0$) means the reaction is exothermic ($q_{\text{rxn}} < 0$).

▲ **Figure 5.18 Coffee-cup calorimeter.** This simple apparatus is used to measure temperature changes of reactions at constant pressure.

Sample Exercise 5.6

Measuring ΔH Using a Coffee-Cup Calorimeter

When a student mixes 50.0 mL of 1.0 *M* HCl and 50.0 mL of 1.0 *M* NaOH in a coffee-cup calorimeter, the temperature of the resultant solution increases from 21.0 to 27.5°C. Calculate the enthalpy change for the reaction in kJ per mole of HCl (kJ/mol HCl), assuming that the calorimeter loses only a negligible quantity of heat, that the total volume of the solution is 0.10 L, that its density is 1.0 g/mL, and that its specific heat is 4.18 J/g-K.

SOLUTION

Analyze Mixing solutions of HCl and NaOH results in an acid–base reaction:

$$\text{HCl}(aq) + \text{NaOH}(aq) \longrightarrow \text{H}_2\text{O}(l) + \text{NaCl}(aq)$$

We need to calculate the heat produced per mole of HCl, given the temperature increase of the solution, the number of moles of HCl and NaOH involved, and the density and specific heat of the solution.

Plan The total heat produced can be calculated using Equation 5.22. The number of moles of HCl consumed in the reaction must be calculated from the volume and molarity of this substance, and this amount is then used to determine the heat produced per mol HCl.

Solve

Because the total volume of the solution is 0.10 L (or 100 mL), its mass is:	$(100\,\text{mL})(1.0\,\text{g/mL}) = 100\,\text{g}$ (two significant figures)
The temperature change is:	$\Delta T = 27.5°\text{C} - 21.0°\text{C} = 6.5°\text{C} = 6.5\,\text{K}$
Using Equation 5.22, we have:	$q_{\text{rxn}} = -C_s \times m \times \Delta T$ $= -(4.18\,\text{J}/\cancel{\text{g}}\text{-}\cancel{\text{K}})(100\,\cancel{\text{g}})(6.5\,\cancel{\text{K}}) = -2.7 \times 10^3\,\text{J} = -2.7\,\text{kJ}$
Because the process occurs at constant pressure, we denote q_{rxn} as q_P:	$\Delta H = q_P = -2.7\,\text{kJ}$
To express the enthalpy change on a molar basis, we use the fact that the number of moles of HCl is given by the product of the volume ($50.0\,\text{mL} = 00500\,\text{L}$) and concentration ($1.0\,M = 1.0\,\text{mol/L}$) of the HCl solution:	$(0.0500\,\cancel{\text{L}})(1.0\,\text{mol}/\cancel{\text{L}}) = 0.050\,\text{mol}$
Thus, the enthalpy change per mole of HCl is:	$\Delta H = -2.7\,\text{kJ}/0.050\,\text{mol} = -54\,\text{kJ/mol}$

Continued

Check ΔH is negative (exothermic), consistent with the observed increase in the temperature. The magnitude of the molar enthalpy change seems reasonable.

▶ Practice Exercise

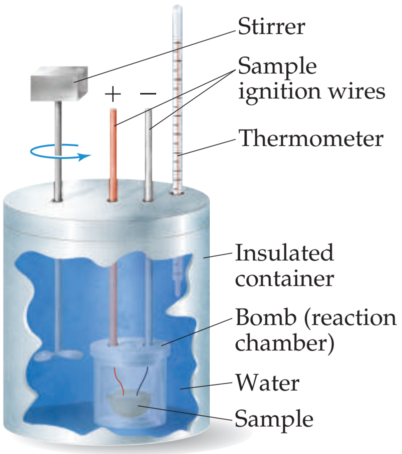
When 50.0 mL of 0.100 *M* $AgNO_3$ and 50.0 mL of 0.100 *M* HCl are mixed in a constant-pressure calorimeter, the temperature of the mixture increases from 22.30 to 23.11°C. The temperature increase is caused by the following reaction:

$$AgNO_3(aq) + HCl(aq) \longrightarrow AgCl(s) + HNO_3(aq)$$

Calculate ΔH for this reaction in kJ/mol $AgNO_3$, assuming that the combined solution has a mass of 100.0 g and a specific heat of 4.18 J/g-°C.

Go Figure

Is the water surrounding the reaction chamber part of the system or the surroundings?



▲ **Figure 5.19** **Bomb calorimeter.**

Bomb Calorimetry (Constant-Volume Calorimetry)

An important type of reaction studied using calorimetry is combustion, in which a compound reacts completely with excess oxygen. (Section 3.2) Combustion reactions are most accurately studied using a **bomb calorimeter** (**Figure 5.19**). The substance to be studied is placed in a small cup within an insulated sealed vessel called a *bomb*. The bomb, which is designed to withstand high pressures, has an inlet valve for adding oxygen and electrical leads for initiating the reaction. After the sample has been placed in the bomb, the bomb is sealed and pressurized with oxygen. It is then placed in the calorimeter and covered with an accurately measured quantity of water. The combustion reaction is initiated by passing an electrical current through a fine wire in contact with the sample. When the wire becomes sufficiently hot, the sample ignites.

The heat released when combustion occurs is absorbed by the water and the various components of the calorimeter (which all together make up the surroundings), causing the water temperature to rise. The change in water temperature caused by the reaction is measured very precisely.

To calculate the heat of combustion from the measured temperature increase, we must know the total heat capacity of the calorimeter, C_{cal}, which typically has the units kJ/°C. This quantity is determined by combusting a sample that releases a known quantity of heat and measuring the temperature change. For example, combustion of exactly 1 g of benzoic acid, C_6H_5COOH, in a bomb calorimeter produces 26.38 kJ of heat. Suppose 1.000 g of benzoic acid is combusted in a calorimeter, leading to a temperature increase of 4.857°C. The heat capacity of the calorimeter is then $C_{cal} = 26.38\text{ kJ}/4.857°\text{C} = 5.431\text{ kJ}/°\text{C}$. Once we know C_{cal}, we can measure temperature changes produced by other reactions, and from these we can calculate the heat evolved in the reaction, q_{rxn}:

$$q_{rxn} = -C_{cal} \times \Delta T \tag{5.23}$$

Because reactions in a bomb calorimeter are carried out at constant volume, the heat transferred corresponds to the change in internal energy, ΔE, rather than the change in enthalpy, ΔH (Equation 5.13). For most reactions, however, the difference between ΔE and ΔH is very small. For the reaction discussed in Sample Exercise 5.7, for example, the difference between ΔE and ΔH is about 1 kJ/mol—a difference of less than 0.1%. It is possible to calculate ΔH from ΔE, but we need not concern ourselves with how these small corrections are made.

Sample Exercise 5.7

Measuring q_{rxn} Using a Bomb Calorimeter

The combustion of methylhydrazine (CH_6N_2), a liquid rocket fuel, produces $N_2(g)$, $CO_2(g)$, and $H_2O(l)$:

$$2\,CH_6N_2(l) + 5\,O_2(g) \longrightarrow 2\,N_2(g) + 2\,CO_2(g) + 6\,H_2O(l)$$

When 4.00 g of methylhydrazine is combusted in a bomb calorimeter, the temperature of the calorimeter increases from 25.00 to 39.50°C. In a separate experiment, the heat capacity of the calorimeter is measured to be 7.794 kJ/°C. Calculate the molar heat of reaction for the combustion of CH_6N_2.

SOLUTION

Analyze We are given ΔT, the heat capacity of the calorimeter (C_{cal}), and the amount of reactant combusted. Our goal is to calculate the enthalpy change per mole of methylhydrazine combusted.

Plan We will first calculate the heat evolved for the combustion of the 4.00-g sample. We will then convert this heat to a molar quantity.

Solve For combustion of the 4.00-g sample of methylhydrazine, the temperature change of the calorimeter is:

$$\Delta T = (39.50°\text{C} - 25.00°\text{C}) = 14.50°\text{C}$$

We can use ΔT and the value for C_{cal} to calculate the heat of reaction (Equation 5.23):

$$q_{rxn} = -C_{cal} \times \Delta T = -(7.794\ \text{kJ}/°\cancel{\text{C}})(14.50°\cancel{\text{C}}) = -113.0\ \text{kJ}$$

We can readily convert this value to the heat of reaction for a mole of CH_6N_2:

$$\left(\frac{-113.0\ \text{kJ}}{4.00\ \cancel{\text{g}\ CH_6N_2}}\right) \times \left(\frac{46.1\ \cancel{\text{g}\ CH_6N_2}}{1\ \text{mol}\ CH_6N_2}\right) = -1.30 \times 10^3\ \text{kJ/mol}\ CH_6N_2$$

Check The units cancel properly, and the sign of the answer is negative, as it should be for an exothermic reaction. The magnitude of the answer seems reasonable.

▶ Practice Exercise

A 0.5865-g sample of lactic acid ($HC_3H_5O_3$) reacts with oxygen in a calorimeter whose heat capacity is 4.812 kJ/°C. The temperature increases from 23.10 to 24.95°C. Calculate the heat of combustion of lactic acid (**a**) per gram and (**b**) per mole.

CHEMISTRY AND LIFE The Regulation of Body Temperature

Are you running a fever? For most of us, being asked that question was one of our first introductions to medical diagnosis. Indeed, a deviation in body temperature of only a few degrees indicates something is amiss. Maintaining a near-constant temperature is one of the primary physiological functions of the human body.

To understand how the body's heating and cooling mechanisms operate, we can view the body as a thermodynamic system. The body increases its internal energy content by ingesting foods from the surroundings. The foods, such as glucose ($C_6H_{12}O_6$), are metabolized—a process that is essentially controlled oxidation to CO_2 and H_2O:

$$C_6H_{12}O_6(s) + 6\,O_2(g) \longrightarrow 6\,CO_2(g) + 6\,H_2O(l) \qquad \Delta H = -2803\ \text{kJ}$$

Roughly 40% of the energy produced is ultimately used to do work in the form of muscle contractions and nerve cell activities. The remainder is released as heat, part of which is used to maintain body temperature. When the body produces too much heat, as in times of heavy physical exertion, it dissipates the excess to the surroundings.

Heat is transferred from the body to its surroundings primarily by *radiation*, *convection*, and *evaporation*. Radiation is the direct loss of heat from the body to cooler surroundings, much as a hot stovetop radiates heat to its surroundings. Convection is heat loss by virtue of heating air that is in contact with the body. The heated air rises and is replaced with cooler air, and the process continues. Warm clothing reduces convective heat loss in cold weather. Evaporative cooling occurs when perspiration is generated at the skin surface by the sweat glands (Figure 5.20). Heat is removed from the body as the perspiration evaporates. Perspiration is predominantly water, so the process is the endothermic conversion of liquid water into water vapor:

$$H_2O(l) \longrightarrow H_2O(g) \qquad \Delta H = +44.0\ \text{kJ}$$

▲ **Figure 5.20 Perspiration, a mechanism to cool the human body.**

The speed with which evaporative cooling occurs decreases as the atmospheric humidity increases, which is why we feel more sweaty and uncomfortable on hot, humid days.

When body temperature becomes too high, heat loss increases in two principal ways. First, blood flow near the skin surface increases, which allows for increased radiational and convective cooling. The reddish, "flushed" appearance of a hot individual is due to this increased blood flow. Second, we sweat, which increases evaporative cooling. During extreme activity, the amount of perspiration can be as high as 2 to 4 liters per hour. As a result, the body's water supply must be replenished during these periods. If the body loses too much liquid through perspiration, it will no longer be able to cool itself and blood volume will decrease, which can lead to either *heat exhaustion* or the more serious *heat stroke*. However, replenishing water without replenishing the electrolytes lost during perspiration can also lead to serious problems. If the normal blood sodium level drops too low, dizziness and confusion set in, and the condition (called *hyponatremia*) can become critical. Drinking a sport drink that contains some electrolytes helps to prevent this problem.

When body temperature drops too low, blood flow to the skin surface decreases, thereby decreasing heat loss. The lower temperature also triggers small involuntary contractions of the muscles (shivering); the biochemical reactions that generate the energy to do this work also generate heat for the body. If the body is unable to maintain a normal temperature, the very dangerous condition called *hypothermia* can result.

Self-Assessment Exercises

SAE 5.11 The specific heat of the metallic element rhodium is 0.240 J/g-K at 25 °C. If 586 J of heat is added to an 80.0 g block of rhodium metal that is initially at 25.0 °C, what is the expected final temperature of the block? (**a**) 26.8 °C (**b**) 30.5 °C (**c**) 32.3 °C (**d**) 55.5 °C (**e**) 2470 °C

SAE 5.12 When 20.0 g of aqueous solution B(*aq*) at 22.0 °C is added to 60.0 g of aqueous solution A(*aq*), also at 22.0 °C, in a coffee-cup calorimeter (Figure 5.18), the two substances react and the temperature of the mixed solution rises to 34.3 °C. What is the quantity of heat, in kJ, released during this reaction? Assume that the specific heat of the mixed solution is the same as that of pure water (4.18 J/g-K). (**a**) 3.08 kJ (**b**) 4.11 kJ (**c**) 7.36 kJ (**d**) 11.5 kJ

Continued

SAE 5.13 When a 4.25-g sample of solid sodium nitrate dissolves in 50.0 g of water in a coffee-cup calorimeter (Figure 5.18), the temperature rises from 24.00 °C to 28.78 °C. What is ΔH (in kJ/mol $NaNO_3$) for the dissolution of sodium nitrate:

$$NaNO_3(s) \longrightarrow Na^+(aq) + NO_3^-(aq)$$

Assume that the specific heat of the solution is the same as that of pure water (4.18 J/g-K). **(a)** −1.08 kJ/mol **(b)** −1.24 kJ/mol **(c)** −5.19 kJ/mol **(d)** −20.0 kJ/mol **(e)** −21.7 kJ/mol

SAE 5.14 A 3.50-g sample of naphthalene ($C_{10}H_8$) is burned in a bomb calorimeter whose total heat capacity is 9.46 kJ/°C. The temperature of the calorimeter increases from 24.1 to 39.0 °C. What is the heat of combustion per gram of naphthalene? **(a)** 40.3 kJ/g **(b)** 105 kJ/g **(c)** 141 kJ/g **(d)** 5160 kJ/g

5.6 | Hess's Law

Learning Objectives

When you finish Section 5.6, you should be able to:

- Use Hess's law to determine ΔH for a reaction that is written as a series of steps.

In this section, we show that it is often possible to calculate the ΔH for a reaction from the tabulated ΔH values of other reactions. Thus, it is not necessary to make calorimetric measurements for all reactions.

Because enthalpy is a state function, the enthalpy change, ΔH, associated with any chemical process depends only on the amount of matter that undergoes change and on the nature of the initial state of the reactants and the final state of the products. This means that regardless of whether a particular reaction is carried out in one step or in a series of steps, the sum of the enthalpy changes associated with the individual steps must be the same as the enthalpy change associated with the one-step process. As an example, combustion of methane gas, $CH_4(g)$, to form $CO_2(g)$ and $H_2O(l)$ can be thought of as occurring in one step, as represented on the left in Figure 5.21, or in two steps, as represented on the right in Figure 5.21: (1) combustion of $CH_4(g)$ to form $CO_2(g)$ and $H_2O(g)$ and (2) condensation of $H_2O(g)$ to form $H_2O(l)$. The enthalpy change for the overall process is the sum of the enthalpy changes for these two steps:

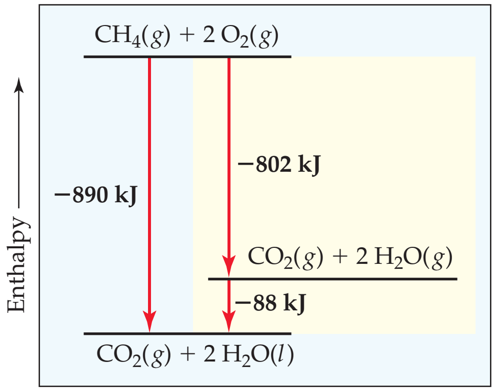
$$\begin{array}{llr}
 & CH_4(g) + 2\,O_2(g) \longrightarrow CO_2(g) + 2\,H_2O(g) & \Delta H = -802\text{ kJ} \\
\text{(Add)} & 2\,H_2O(g) \longrightarrow 2\,H_2O(l) & \Delta H = -88\text{ kJ} \\
\hline
 & CH_4(g) + 2\,O_2(g) + 2\,H_2O(g) \longrightarrow CO_2(g) + 2\,H_2O(l) + 2\,H_2O(g) & \Delta H = -890\text{ kJ}
\end{array}$$

The net equation is

$$CH_4(g) + 2\,O_2(g) \longrightarrow CO_2(g) + 2\,H_2O(l) \quad \Delta H = -890\text{ kJ}$$

Go Figure

What process corresponds to the −88 kJ enthalpy change?



▲ **Figure 5.21 Enthalpy diagram for combustion of one mole of methane.** The enthalpy change of the one-step reaction equals the sum of the enthalpy changes of the reaction run in two steps: −890 kJ = −802 kJ + (−88 kJ).

Hess's law states that *if a reaction is carried out in a series of steps, ΔH for the overall reaction equals the sum of the enthalpy changes for the individual steps*. The overall enthalpy change for the process is independent of both the number of steps and the path by which the reaction is carried out. This law is a consequence of the fact that enthalpy is a state function. We can therefore calculate ΔH for any process as long as we find a route for which ΔH is known for each step. This means that a relatively small number of experimental measurements can be used to calculate ΔH for a vast number of reactions.

Hess's law provides a useful means of calculating energy changes that are difficult to measure directly. For instance, we can use the enthalpy changes for combustion reactions, which are fairly straightforward to measure, to determine the enthalpy change for a reaction that does not involve combustion. An example of this process is given in Sample Exercise 5.8, where we use combustion reactions to determine the enthalpy change when $C(s)$ reacts with $H_2(g)$.

The key point of these examples is that H is a state function.

> *Because H is a state function, for a particular set of reactants and products, ΔH is the same whether the reaction takes place in one step or in a series of steps.*

Sample Exercise 5.8

Using Hess's Law with Three Equations to Calculate ΔH

Calculate ΔH for the reaction

$$2\,C(s) + H_2(g) \longrightarrow C_2H_2(g)$$

given the following chemical equations and their respective enthalpy changes:

$$\begin{array}{rcll}
C_2H_2(g) + \frac{5}{2}O_2(g) & \longrightarrow & 2\,CO_2(g) + H_2O(l) & \Delta H = -1299.6\text{ kJ} \\
C(s) + O_2(g) & \longrightarrow & CO_2(g) & \Delta H = -393.5\text{ kJ} \\
H_2(g) + \frac{1}{2}O_2(g) & \longrightarrow & H_2O(l) & \Delta H = -285.8\text{ kJ}
\end{array}$$

SOLUTION

Analyze We are given a chemical equation and asked to calculate its ΔH using three chemical equations and their associated enthalpy changes.

Plan We will use Hess's law, summing the three equations or their reverses and multiplying each by an appropriate coefficient so that they add to give the net equation for the reaction of interest. At the same time, we must keep track of the ΔH values, reversing their signs if the reactions are reversed and multiplying them by whatever coefficient is employed in the equation.

Solve Because the target equation has C_2H_2 as a product, we turn the first equation around; the sign of ΔH is therefore changed. The desired equation has 2 C(s) as a reactant, so we multiply the second equation and its ΔH by 2. Because the target equation has H_2 as a reactant, we keep the third equation as it is. We then add the three equations and their enthalpy changes in accordance with Hess's law:

$$\begin{array}{rcll}
2\,\cancel{CO_2(g)} + \cancel{H_2O(l)} & \longrightarrow & C_2H_2(g) + \frac{5}{2}\cancel{O_2(g)} & \Delta H = +1299.6\text{ kJ} \\
2\,C(s) + 2\,\cancel{O_2(g)} & \longrightarrow & 2\,\cancel{CO_2(g)} & \Delta H = -787.0\text{ kJ} \\
H_2(g) + \frac{1}{2}\cancel{O_2(g)} & \longrightarrow & \cancel{H_2O(l)} & \Delta H = -285.8\text{ kJ} \\
\hline
2\,C(s) + H_2(g) & \longrightarrow & C_2H_2(g) & \Delta H = 226.8\text{ kJ}
\end{array}$$

When the equations are added, the total amounts of CO_2, O_2, and H_2O are the same on both sides of the arrow, so these are canceled when writing the net equation.

Check The procedure must be correct because we obtained the correct net equation. In cases like this, you should go back over the numerical manipulations of the ΔH values to ensure that you did not make an inadvertent error with signs or coefficients.

▶ Practice Exercise

Calculate ΔH for the reaction

$$NO(g) + O(g) \longrightarrow NO_2(g)$$

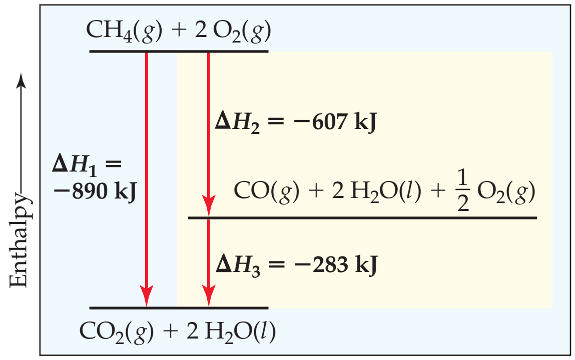
given the following information:

$$\begin{array}{rcll}
NO(g) + O_3(g) & \longrightarrow & NO_2(g) + O_2(g) & \Delta H = -198.9\text{ kJ} \\
O_3(g) & \longrightarrow & \frac{3}{2}O_2(g) & \Delta H = -142.3\text{ kJ} \\
O_2(g) & \longrightarrow & 2\,O(g) & \Delta H = 495.0\text{ kJ}
\end{array}$$

We reinforce this point by giving one more example of an enthalpy diagram and Hess's law. Again we use combustion of methane to form CO_2 and H_2O, our reaction from Figure 5.21. This time we envision a different two-step path, with the initial formation of CO, which is then combusted to CO_2 (**Figure 5.22**). Even though the two-step path is different from that in Figure 5.21, the overall reaction again has $\Delta H_1 = -890$ kJ. Because H is a state function, both paths *must* produce the same value of ΔH. In Figure 5.22, that means $\Delta H_1 = \Delta H_2 + \Delta H_3$. We will soon see that breaking up reactions in this way allows us to derive the enthalpy changes for reactions that are hard to carry out in the laboratory.

Go Figure

Suppose the overall reaction were modified to produce 2 $H_2O(g)$ rather than 2 $H_2O(l)$. Would any of the values of ΔH in the diagram stay the same?



◀ **Figure 5.22 Enthalpy diagram illustrating Hess's law.** The net reaction is the same as in Figure 5.21, but here we imagine different reactions in our two-step version. As long as we can write a series of equations, each with a known value of ΔH that add up to the equation we need, we can calculate the overall ΔH.

Self-Assessment Exercises

SAE 5.15 Consider the following hypothetical reactions:

$$\begin{aligned} X &\longrightarrow Y \quad \Delta H_1 \\ Z &\longrightarrow Y \quad \Delta H_2 \end{aligned}$$

Which of the following statements about these reactions is or are *true*?

(**i**) The enthalpy change for the reaction Y $\longrightarrow$ X is $-\Delta H_1$.
(**ii**) The enthalpy change for the reaction 2 Z $\longrightarrow$ 2 Y is $2(\Delta H_2)$.
(**iii**) The enthalpy change for the reaction X $\longrightarrow$ Z is $\Delta H_1 + \Delta H_2$.

(**a**) Only one of the statements is true. (**b**) i and ii are true. (**c**) i and iii are true. (**d**) ii and iii are true. (**e**) All three statements are true.

SAE 5.16 From the following enthalpies of reaction

$$2\,H_2(g) + O_2(g) \longrightarrow 2\,H_2O(l) \quad \Delta H = -572\text{ kJ}$$

$$H_2(g) + O_2(g) \longrightarrow H_2O_2(l) \quad \Delta H = -188\text{ kJ}$$

calculate ΔH for the reaction

$$2\,H_2O_2(l) \longrightarrow 2\,H_2O(l) + O_2(g).$$

(**a**) −196 kJ (**b**) −384 kJ (**c**) −760 kJ (**d**) −948 kJ

SAE 5.17 Given the following enthalpies of reaction

$$C_2H_4(g) + 3\,O_2(g) \longrightarrow 2\,CO_2(g) + 2\,H_2O(g) \quad \Delta H = -1323\text{ kJ}$$

$$2\,CO(g) + O_2(g) \longrightarrow 2\,CO_2(g) \quad \Delta H = -566\text{ kJ}$$

$$H_2O(l) \longrightarrow H_2O(g) \quad \Delta H = +44\text{ kJ}$$

use Hess's law to calculate ΔH for the reaction

$$C_2H_4(g) + 2\,O_2(g) \longrightarrow 2\,CO(g) + 2\,H_2O(l).$$

(**a**) −757 kJ (**b**) −801 kJ (**c**) −845 kJ (**d**) −1977 kJ

5.7 | Enthalpies of Formation

Learning Objectives

When you finish Section 5.7, you should be able to:

- Describe what is meant by a standard enthalpy of formation, ΔH_f°, of a substance.
- Use tabulated enthalpies of formation to calculate the enthalpies of reactions.

We can use the methods just discussed to calculate enthalpy changes for a great many reactions from tabulated ΔH values. A particularly important process used for tabulating and using thermochemical data is the formation of a compound from its constituent elements. The enthalpy change associated with this process is called the **enthalpy of formation** (or *heat of formation*), ΔH_f, where the subscript *f* indicates that the substance has been *formed* from its constituent elements.

The magnitude of any enthalpy change depends on the temperature, pressure, and state (gas, liquid, or solid crystalline form) of the reactants and products. To compare enthalpies of different reactions, we must define a set of conditions, called a *standard state*, at which most enthalpies are tabulated. The standard state of a substance is its pure form at atmospheric pressure (1 atm) and the temperature of interest, which we usually choose to be 298 K (25°C).* The **standard enthalpy change** of a reaction is defined as the enthalpy change when all reactants and products are in their standard states. We denote a standard enthalpy change as ΔH°, where the superscript ° indicates standard-state conditions.

The **standard enthalpy of formation** of a compound, ΔH_f°, is the change in enthalpy for the reaction that forms one mole of the compound from its elements with all substances in their standard states:

$$\underset{\text{(in standard state)}}{\text{elements}} \longrightarrow \underset{\text{(1 mol in standard state)}}{\text{compound}} \qquad \Delta H_{\text{rxn}} = \Delta H_f^\circ \qquad [5.24]$$

We usually report ΔH_f° values at 298 K. If an element exists in more than one form under standard conditions, the most stable form of the element is used for the formation reaction. For example, the standard enthalpy of formation for ethanol, C_2H_5OH, is the enthalpy change for the reaction

$$2\,C(\textit{graphite}) + 3\,H_2(g) + \tfrac{1}{2}\,O_2(g) \longrightarrow C_2H_5OH(l) \qquad \Delta H_f^\circ = -277.7\text{ kJ} \qquad [5.25]$$

The elemental source of oxygen is O_2, not O or O_3, because O_2 is the stable form of oxygen at 298 K and atmospheric pressure. Similarly, the elemental source of carbon is graphite

---

*The definition of the standard state for gases has been changed to 1 bar (1 atm = 1.013 bar), a slightly lower pressure than 1 atm. For most purposes, this change makes very little difference in the standard enthalpy changes.

TABLE 5.3 **Standard Enthalpies of Formation, ΔH_f°, at 298 K**

Substance	Formula	ΔH_f° (kJ/mol)	Substance	Formula	ΔH_f° (kJ/mol)
Acetylene	$C_2H_2(g)$	227.4	Hydrogen chloride	$HCl(g)$	−92.31
Ammonia	$NH_3(g)$	−45.94	Hydrogen fluoride	$HF(g)$	−273.30
Benzene	$C_6H_6(l)$	49.0	Hydrogen iodide	$HI(g)$	26.50
Calcium carbonate	$CaCO_3(s)$	−1207.1	Methane	$CH_4(g)$	−74.6
Calcium oxide	$CaO(s)$	−635.1	Methanol	$CH_3OH(l)$	−238.4
Carbon dioxide	$CO_2(g)$	−393.5	Propane	$C_3H_8(g)$	−103.85
Carbon monoxide	$CO(g)$	−110.5	Silver chloride	$AgCl(s)$	−127.0
Diamond	$C(s)$	1.88	Sodium bicarbonate	$NaHCO_3(s)$	−947.7
Ethane	$C_2H_6(g)$	−84.68	Sodium carbonate	$Na_2CO_3(s)$	−1130.8
Ethanol	$C_2H_5OH(l)$	−277.0	Sodium chloride	$NaCl(s)$	−411.1
Ethylene	$C_2H_4(g)$	52.4	Sucrose	$C_{12}H_{22}O_{11}(s)$	−2221
Glucose	$C_6H_{12}O_6(s)$	−1273	Water	$H_2O(l)$	−285.8
Hydrogen bromide	$HBr(g)$	−36.29	Water vapor	$H_2O(g)$	−241.8

and not diamond because graphite is the more stable (lower-energy) form at 298 K and atmospheric pressure. Likewise, the most stable form of hydrogen under standard conditions is $H_2(g)$, so this is used as the source of hydrogen in Equation 5.25.

The stoichiometry of formation reactions always indicates that one mole of the desired substance is produced, as in Equation 5.25. As a result, standard enthalpies of formation are reported in kJ/mol of the substance being formed. Some values are given in **Table 5.3**, and a more extensive table is provided in Appendix C.

By definition, *the standard enthalpy of formation of the most stable form of any element is zero*. Thus, the values of ΔH_f° for C(*graphite*), $H_2(g)$, $O_2(g)$, and the standard states of other elements are zero by definition.

Sample Exercise 5.9

Equations Associated with Enthalpies of Formation

For which of these reactions at 25°C does the enthalpy change represent a standard enthalpy of formation? For each that does not, what changes are needed to make it an equation whose ΔH is an enthalpy of formation?

(a) $2\,Na(s) + \frac{1}{2}O_2(g) \longrightarrow Na_2O(s)$

(b) $2\,K(l) + Cl_2(g) \longrightarrow 2\,KCl(s)$

(c) $C_6H_{12}O_6(s) \longrightarrow 6\,C(\textit{diamond}) + 6\,H_2(g) + 3\,O_2(g)$

SOLUTION

Analyze The standard enthalpy of formation is represented by a reaction in which each reactant is an element in its standard state and the product is one mole of the compound.

Plan We need to examine each equation to determine (1) whether the reaction is one in which one mole of substance is formed from the elements, and (2) whether the reactant elements are in their standard states.

Solve In (**a**) 1 mol Na_2O is formed from the elements sodium and oxygen in their proper states, solid Na and O_2 gas, respectively. Therefore, the enthalpy change for reaction (**a**) corresponds to a standard enthalpy of formation.

In (**b**) potassium is given as a liquid. It must be changed to the solid form, its standard state at room temperature. Furthermore, 2 mol KCl are formed, so the enthalpy change for the reaction as written is twice the standard enthalpy of formation of KCl(*s*). The equation for the formation reaction of 1 mol of KCl(*s*) is

$$K(s) + \tfrac{1}{2}Cl_2(g) \longrightarrow KCl(s)$$

Reaction (**c**) does not form a substance from its elements. Instead, a substance decomposes to its elements, so this reaction must be reversed. Next, the element carbon is given as diamond, whereas graphite is the standard state of carbon at room temperature and 1 atm pressure. The equation that correctly represents the enthalpy of formation of glucose from its elements is

$$6\,C(\textit{graphite}) + 6\,H_2(g) + 3\,O_2(g) \longrightarrow C_6H_{12}O_6(s)$$

▶ Practice Exercise

Write the equation corresponding to the standard enthalpy of formation of liquid carbon tetrachloride (CCl_4) and look up ΔH_f° for this compound in Appendix C.

Using Enthalpies of Formation to Calculate Enthalpies of Reaction

We can use Hess's law and tabulations of ΔH_f° values, such as those in Table 5.3 and Appendix C, to calculate the standard enthalpy change for any reaction for which we know the ΔH_f° values for all reactants and products. For example, consider the combustion of propane under standard conditions:

$$C_3H_8(g) + 5\,O_2(g) \longrightarrow 3\,CO_2(g) + 4\,H_2O(l)$$

We can write this equation as the sum of three equations associated with standard enthalpies of formation:

$$\begin{array}{rll}
C_3H_8(g) \longrightarrow 3\,C(s) + 4\,H_2(g) & \Delta H_1 = -(1\text{ mol } C_3H_8)[\Delta H_f^\circ \text{ for } C_3H_8(g)] & [5.26] \\
3\,C(s) + 3\,O_2(g) \longrightarrow 3\,CO_2(g) & \Delta H_2 = (3\text{ mol } CO_2)[\Delta H_f^\circ \text{ for } CO_2(g)] & [5.27] \\
4\,H_2(g) + 2\,O_2(g) \longrightarrow 4\,H_2O(l) & \Delta H_3 = (4\text{ mol } H_2O)[\Delta H_f^\circ \text{for } H_2O(l)] & [5.28] \\
\hline
C_3H_8(g) + 5\,O_2(g) \longrightarrow 3\,CO_2(g) + 4\,H_2O(l) & \Delta H^\circ_{\text{rxn}} = \Delta H_1 + \Delta H_2 + \Delta H_3 & [5.29]
\end{array}$$

It is sometimes useful to add subscripts to the enthalpy changes, as we have done here, to keep track of the associations between reactions and their ΔH values. Also, remember that we don't need to include ΔH_f° for $O_2(g)$ in our sum because it is zero by definition.

We can now use values from Table 5.3 to calculate $\Delta H^\circ_{\text{rxn}}$:

$$\begin{aligned}
\Delta H^\circ_{\text{rxn}} &= \Delta H_1 + \Delta H_2 + \Delta H_3 \\
&= -[1\text{ mol } C_3H_8(g)](-103.85\text{ kJ/mol}) + [3\text{ mol } CO_2(g)](-393.5\text{ kJ/mol}) \\
&\quad +[4\text{ mol } H_2O(l)](-285.8\text{ kJ/mol}) \\
&= -2220\text{ kJ} \qquad [5.30]
\end{aligned}$$

The enthalpy diagram in **Figure 5.23** shows the components of this calculation. In Step ❶ the reactants are decomposed into their constituent elements in their standard states. In Steps ❷ and ❸ the products are formed from the elements. Several aspects of how we use enthalpy changes in this process depend on the guidelines we discussed in Section 5.4.

❶ **Decomposition**. Equation 5.26 is the reverse of the formation reaction for $C_3H_8(g)$, so the enthalpy change for this decomposition reaction is the negative of the ΔH_f° value for the formation of 1 mol of propane: $-\Delta H_f^\circ[C_3H_8(g)]$.

❷ **Formation of CO_2**. Equation 5.27 is the formation reaction for 3 mol of $CO_2(g)$. Because enthalpy is an extensive property, the enthalpy change for this step is $3\Delta H_f^\circ[CO_2(g)]$.

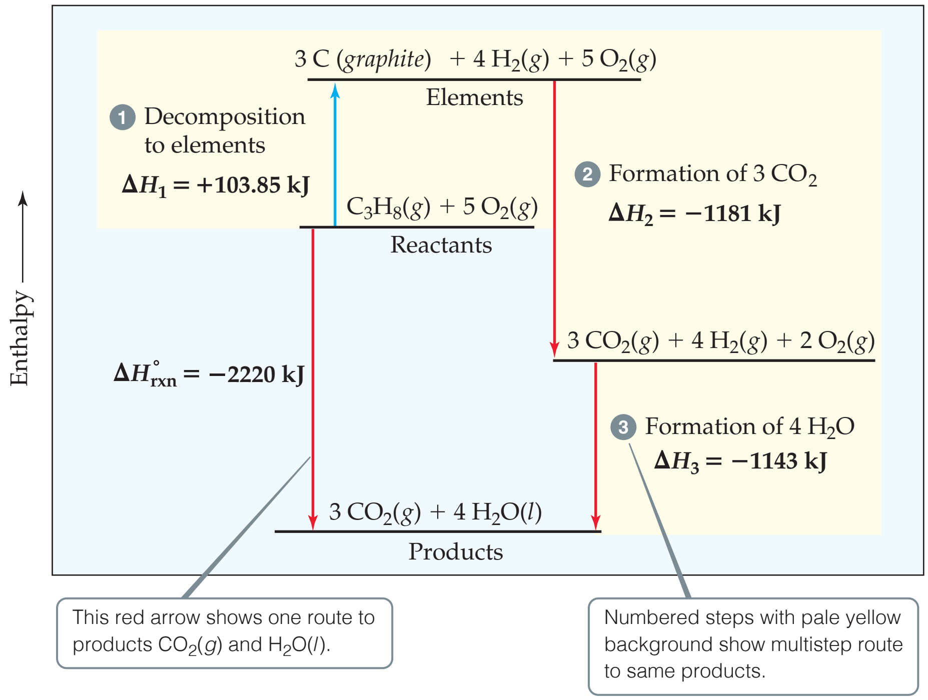
❸ **Formation of H_2O**. The enthalpy change for Equation 5.28, the formation of 4 mol of H_2O, is $4\Delta H_f^\circ[H_2O(l)]$. The reaction specifies that $H_2O(l)$ is produced, so be careful to use the value of ΔH_f° for $H_2O(l)$ and not the value for $H_2O(g)$.

Note that in this analysis *the stoichiometric coefficients in the balanced equation represent the number of moles of each substance*. For Equation 5.29, therefore, $\Delta H^\circ_{\text{rxn}} = -2220$ kJ represents the enthalpy change for the reaction of 1 mol C_3H_8 and 5 mol O_2 to form 3 mol CO_2 and 4 mol H_2O.

We can break down any reaction into formation reactions as we have done here. When we do, we obtain the general result that the standard enthalpy change of a reaction is the sum of the standard enthalpies of formation of the products minus the standard enthalpies of formation of the reactants:

$$\Delta H^\circ_{\text{rxn}} = \sum n\Delta H_f^\circ(\text{products}) - \sum m\Delta H_f^\circ(\text{reactants}) \qquad [5.31]$$

The symbol $\sum$ (sigma) means "the sum of," and n and m are the stoichiometric coefficients of the relevant chemical equation. The first term on the right in Equation 5.31 represents the formation reactions of the products, which are written in the "forward" direction in the chemical equation—that is, elements reacting to form products. This term is analogous to Equations 5.27 and 5.28. The second term on the right in Equation 5.31 represents the reverse of the formation reactions of the reactants, analogous to Equation 5.26, which is why this term is preceded by a minus sign. When applying



This red arrow shows one route to products $CO_2(g)$ and $H_2O(l)$.

Numbered steps with pale yellow background show multistep route to same products.

Figure 5.23 Enthalpy diagram for propane combustion.

Equation 5.31, remember that ΔH_f° for any element in its most stable form [such as $O_2(g)$ in Equation 5.29] is zero and can therefore be essentially ignored in the summations.

Sample Exercise 5.10

Calculating an Enthalpy of Reaction from Enthalpies of Formation

(a) Calculate the standard enthalpy change for the combustion of one mole of benzene, $C_6H_6(l)$, to $CO_2(g)$ and $H_2O(l)$.

(b) Compare the quantity of heat produced by the combustion of 1.00 g propane with that produced by 1.00 g benzene.

SOLUTION

Analyze (**a**) We are given a reaction [combustion of $C_6H_6(l)$ to form $CO_2(g)$ and $H_2O(l)$] and asked to calculate its standard enthalpy change, ΔH°. (**b**) We then need to compare the quantity of heat produced by combustion of 1.00 g C_6H_6 with that produced by 1.00 g C_3H_8, whose combustion was treated previously in the text. (See Equations 5.29 and 5.30.)

Plan (**a**) We first write the balanced equation for the combustion of C_6H_6. We then look up ΔH_f° values in Appendix C or in Table 5.3 and apply Equation 5.31 to calculate the enthalpy change for the reaction. (**b**) We use the molar mass of C_6H_6 to change the enthalpy change per mole to that per gram. We similarly use the molar mass of C_3H_8 and the enthalpy change per mole calculated in the text previously to calculate the enthalpy change per gram of that substance.

Solve

(**a**) We know that a combustion reaction involves $O_2(g)$ as a reactant. Thus, the balanced equation for the combustion reaction of 1 mol $C_6H_6(l)$ is:

$$C_6H_6(l) + \tfrac{15}{2}O_2(g) \longrightarrow 6\,CO_2(g) + 3\,H_2O(l)$$

We can calculate ΔH° for this reaction by using Equation 5.31 and data in Table 5.3. Remember to multiply the ΔH_f° value for each substance in the reaction by that substance's stoichiometric coefficient. The standard state of oxygen is $O_2(g)$, so $\Delta H_f^\circ[O_2(g)] = 0$.

$$\begin{aligned}\Delta H^\circ_{rxn} &= [6\Delta H_f^\circ(CO_2) + 3\Delta H_f^\circ(H_2O)] - [\Delta H_f^\circ(C_6H_6) + \tfrac{15}{2}\Delta H_f^\circ(O_2)]\\ &= [6(-393.5\text{ kJ}) + 3(-285.8\text{ kJ})] - [(49.0\text{ kJ}) + \tfrac{15}{2}(0\text{ kJ})]\\ &= (-2361 - 857.4 - 49.0)\text{ kJ}\\ &= -3267\text{ kJ}\end{aligned}$$

(**b**) From the example worked in the text, $\Delta H^\circ = -2220$ kJ for the combustion of one mole of propane. In part (a) of this exercise, we determined that $\Delta H^\circ = -3267$ kJ for the combustion of one mole of benzene. To determine the heat of combustion per gram of each substance, we use the molar masses to convert moles to grams:

$$C_3H_8(g){:}\quad (-2220\text{ kJ}/\cancel{\text{mol}})(1\,\cancel{\text{mol}}/44.1\text{ g}) = -50.3\text{ kJ/g}$$
$$C_6H_6(l){:}\quad (-3267\text{ kJ}/\cancel{\text{mol}})(1\,\cancel{\text{mol}}/78.1\text{ g}) = -41.8\text{ kJ/g}$$

Comment Both propane and benzene are hydrocarbons. As a rule, the energy obtained from the combustion of a gram of hydrocarbon is between 40 and 50 kJ.

Practice Exercise

Use Table 5.3 to calculate the enthalpy change for the combustion of 1 mol of ethanol:

$$C_2H_5OH(l) + 3\,O_2(g) \longrightarrow 2\,CO_2(g) + 3\,H_2O(l)$$

Sample Exercise 5.11

Calculating an Enthalpy of Formation Using an Enthalpy of Reaction

The standard enthalpy change for the reaction $CaCO_3(s) \longrightarrow CaO(s) + CO_2(g)$ is 178.1 kJ. Use Table 5.3 to calculate the standard enthalpy of formation of $CaCO_3(s)$.

SOLUTION

Analyze Our goal is to obtain $\Delta H_f^\circ[CaCO_3]$.

Plan We begin by writing the expression for the standard enthalpy change for the reaction:

$$\Delta H_{rxn}^\circ = \Delta H_f^\circ[CaO] + \Delta H_f^\circ[CO_2] - \Delta H_f^\circ[CaCO_3]$$

Solve Inserting the given ΔH_{rxn}° and the known ΔH_f° values from Table 5.3 or Appendix C, we have:

$$178.1\text{ kJ} = -635.5\text{ kJ} - 393.5\text{ kJ} - \Delta H_f^\circ[CaCO_3]$$

Solving for $\Delta H_f^\circ[CaCO_3]$ gives:

$$\Delta H_f^\circ[CaCO_3] = -1207.1\text{ kJ/mol}$$

Check We expect the enthalpy of formation of a stable solid such as calcium carbonate to be negative, as obtained.

Practice Exercise

Given the following standard enthalpy change, use the standard enthalpies of formation in Table 5.3 to calculate the standard enthalpy of formation of $CuO(s)$:

$$CuO(s) + H_2(g) \longrightarrow Cu(s) + H_2O(l) \qquad \Delta H^\circ = -129.7\text{ kJ}$$

Self-Assessment Exercises

SAE 5.18 Which of the following statements about standard enthalpies of formation is *false*? (**a**) Standard enthalpies of formation are always positive numbers or zero. (**b**) The standard enthalpy of formation for a compound is the enthalpy for the reaction in which one mole of the compound is made from its elements under standard conditions. (**c**) The standard enthalpy of formation of an element in its most stable form under standard conditions is zero. (**d**) The standard state of a pure substance is its form at atmospheric pressure and a specified temperature, which is usually 298 K. (**e**) The standard enthalpy of formation of a substance will be different for different phases of the substance.

SAE 5.19 Hypochlorous acid (HOCl) can decompose in the gas phase according to the following balanced equation:

$$2\,HOCl(g) \rightarrow 2\,HCl(g) + O_2(g) \quad \Delta H = -31.0\text{ kJ } (T = 298\text{ K}, P = 1\text{ atm})$$

Using the enthalpy of this reaction and data in Table 5.3, calculate the standard enthalpy of formation for $HOCl(g)$. (**a**) +76.8 kJ/mol (**b**) +61.3 kJ/mol (**c**) −76.8 kJ/mol (**d**) −123 kJ/mol (**e**) −154 kJ/mol

SAE 5.20 Carbon tetrachloride (CCl_4) can react with H_2 to form methane and hydrogen chloride:

$$CCl_4(g) + 4\,H_2(g) \rightarrow CH_4(g) + 4\,HCl(g)$$

ΔH_f° for $CCl_4(g)$ is −106.7 kJ/mol. Other values for ΔH_f° are given in Table 5.3. What is the standard enthalpy change for the above reaction? (**a**) −60.4 kJ (**b**) −337 kJ (**c**) −444 kJ (**d**) −551 kJ (**e**) More information is needed.

5.8 | Bond Enthalpies

Learning Objectives

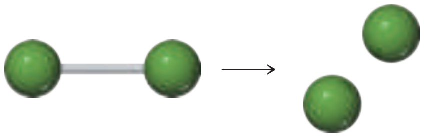
When you finish Section 5.8, you should be able to:

- Describe the concept of average bond enthalpies.
- Use average bond enthalpies to estimate the enthalpies of gas-phase reactions.

The energy changes that accompany chemical reactions are closely related to the changes associated with forming and breaking chemical bonds—breaking bonds requires energy and forming bonds releases energy. In this section we show how enthalpy values can be assigned to individual bonds, which then can be used to estimate enthalpies of reaction.

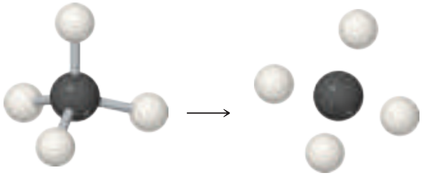
By measuring the enthalpy of a reaction and keeping track of the bonds that are broken and formed, we can assign an enthalpy value to specific bonds. The **bond enthalpy** is the enthalpy change, ΔH, for the breaking of a particular bond in one mole of a gaseous substance. It is easiest to determine bond enthalpies from simple reactions where only one bond is broken, such as the dissociation of $Cl_2(g)$. A Cl_2 molecule is held together by a single covalent bond, which is represented as Cl—Cl. The dissociation of $Cl_2(g)$ into chlorine atoms results when the Cl—Cl bond is broken, as illustrated by the drawing in the margin:

$$Cl_2(g) \rightarrow 2\,Cl(g) \qquad \Delta H = 242\text{ kJ}$$



Because the stoichiometric coefficients represent moles, in this reaction 1 mol of $Cl_2(g)$ produces 2 mol of $Cl(g)$. In the course of the reaction, we are breaking 1 mol of Cl—Cl bonds. Hence, we state that the bond enthalpy for the Cl—Cl bond is 242 kJ/mol. The units kJ/mol for a bond enthalpy refer to the enthalpy *per mole of bonds broken*. The bond enthalpy is a positive number because energy must be supplied from the surroundings to break a bond. We use the letter D followed by the bond in question to represent bond enthalpies. For example, $D(\text{Cl—Cl})$ is the bond enthalpy for the Cl_2 bond, whereas $D(\text{H—Br})$ is the bond enthalpy for the HBr bond.

The previous example shows that it is straightforward to assign bond enthalpies for a reaction involving the breaking of a bond in a diatomic molecule. However, many important bonds, such as the C—H bond, exist only in polyatomic molecules. For these bonds, we usually use average bond enthalpies. For example, the enthalpy change for the process in which a methane molecule is decomposed into its five constituent atoms, as shown in the margin, can be used to define an average bond enthalpy for the C—H bond:

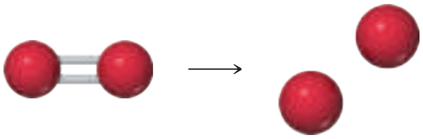


$$\text{CH}_4(g) \longrightarrow \text{C}(g) + 4\text{H}(g) \qquad \Delta H = 1660\text{ kJ}$$

Because there are four equivalent C—H bonds in methane, the enthalpy of this reaction is four times the enthalpy needed to break a single C—H bond. Therefore, the average C—H bond enthalpy in CH_4 is $D(\text{C—H}) = (1660/4)\text{ kJ/mol} = 415\text{ kJ/mol}$.

The exact bond enthalpy for a given pair of atoms, say C—H, depends on the rest of the molecule containing the atom pair. However, the variation from one molecule to another is generally small. If we consider C—H bond enthalpies in many different compounds, we find that the average bond enthalpy is 413 kJ/mol, close to the 415 kJ/mol value we just calculated from for the dissociation of CH_4.

As we explain in later chapters, atom pairs are sometimes held together by two bonds (a *double* bond) or three bonds (a *triple* bond). We can determine the bond enthalpies of multiple bonds in the same way we have just done for single bonds. For example, the oxygen atoms in $O_2(g)$ are held together by a double bond, O═O, rather than a single bond, O—O. If we break a molecule of $O_2(g)$ into two O(g) atoms, we are breaking one O═O double bond, as illustrated in the margin:



$$\text{O═O}(g) \rightarrow 2\,\text{O}(g) \qquad \Delta H = 495\text{ kJ}$$

Because we are breaking 1 mol of O═O double bonds in this process, the bond enthalpy for the O═O bond is 495 kJ/mol.

Table 5.4 lists average bond enthalpies for a number of atom pairs. Note that the bond enthalpy is always a positive quantity because *energy is required to break chemical bonds*. Conversely, *energy is released when a bond forms* between two atoms.

The magnitudes of the bond enthalpies give us important information about the relative strengths of chemical bonds: The greater the bond enthalpy, the stronger the bond. Thus, H—F bonds (567 kJ/mol) are much stronger than F—F bonds (155 kJ/mol). Notice also that double bonds between two atoms are stronger than single bonds between the same atoms, although they are not exactly twice as strong. We consider the variations in bond enthalpy for double and triple bonds in more detail in Chapter 8.

TABLE 5.4 **Average Bond Enthalpies (kJ/mol)**

Bond Enthalpies and the Enthalpies of Reactions

Because enthalpy is a state function, we can use average bond enthalpies to estimate the enthalpies of reactions in which bonds are broken and new bonds are formed. This procedure allows us to estimate quickly whether a given reaction will be endothermic ($\Delta H > 0$) or exothermic ($\Delta H < 0$), even if we do not know ΔH_f° for all of the species involved.

Our strategy for estimating reaction enthalpies is a straightforward application of Hess's law. We use the fact that breaking bonds is always endothermic and that forming bonds is always exothermic. We therefore imagine that the reaction occurs in two steps:

1. We supply enough energy to break those bonds in the reactants that are not present in the products. The enthalpy of the system is increased by the sum of the bond enthalpies of the bonds that are broken.
2. We form the bonds in the products that were not present in the reactants. This step releases energy and therefore lowers the enthalpy of the system by the sum of the bond enthalpies of the bonds that are formed.

The enthalpy of the reaction, ΔH_{rxn}, is thus estimated as the sum of the bond enthalpies of the bonds broken minus the sum of the bond enthalpies of the bonds formed:

$$\Delta H_{\text{rxn}} = \sum \begin{pmatrix}\text{bond enthalpies} \\ \text{of bonds broken}\end{pmatrix} - \sum \begin{pmatrix}\text{bond enthalpies} \\ \text{of bonds formed}\end{pmatrix} \qquad [5.32]$$

If the sum of the bond enthalpies of the bonds broken is greater than the sum of the bond enthalpies of the bonds formed, the reaction is endothermic ($\Delta H_{\text{rxn}} > 0$). Conversely, if the sum of the bond enthalpies of the bonds broken is less than the sum of the bond enthalpies of the bonds formed, the reaction is exothermic ($\Delta H_{\text{rxn}} < 0$).

Consider, for example, the gas-phase reaction between methane, CH_4, and chlorine to produce methyl chloride, CH_3Cl, and hydrogen chloride, HCl:

$$\text{H—CH}_3(g) + \text{Cl—Cl}(g) \longrightarrow \text{Cl—CH}_3(g) + \text{H—Cl}(g) \qquad \Delta H_{\text{rxn}} = \,? \qquad [5.33]$$

Our two-step procedure is outlined in **Figure 5.24**. The following bonds are broken and formed:

Bonds broken: 1 mol C—H, 1 mol Cl—Cl

Bonds formed: 1 mol C—Cl, 1 mol H—Cl

We first supply enough energy to break the C—H and Cl—Cl bonds, which raises the enthalpy of the system (indicated as $\Delta H_1 > 0$ in Figure 5.24). We then form the C—Cl and H—Cl bonds, which release energy and lower the enthalpy of the system ($\Delta H_2 < 0$ in Figure 5.24). Next, we use Equation 5.32 to estimate the enthalpy of the reaction:

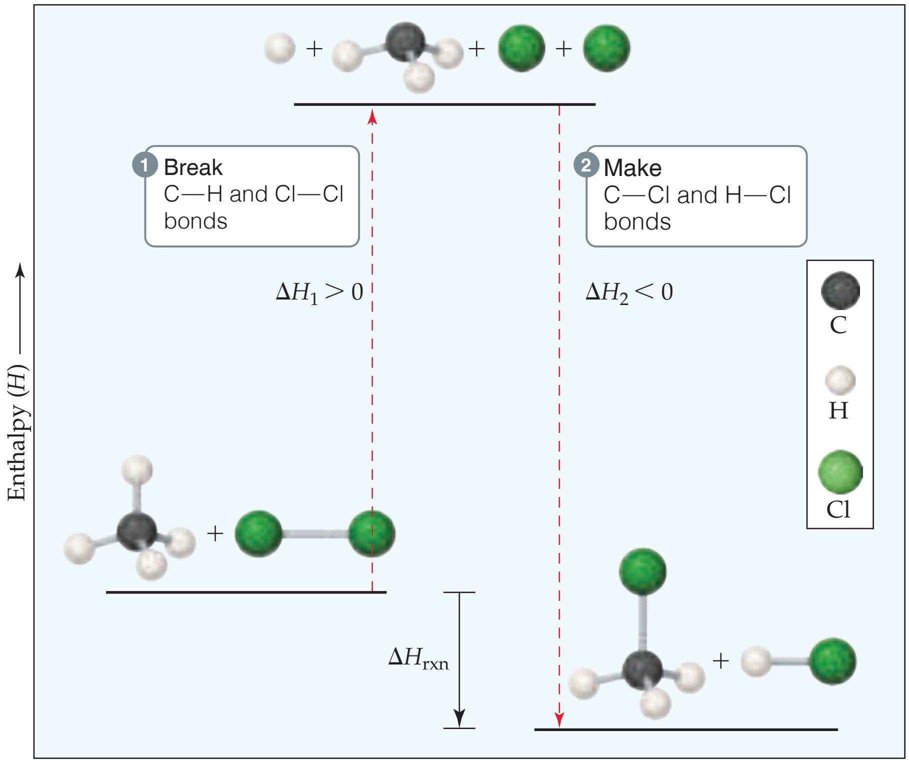
$$\Delta H_{\text{rxn}} = [D(\text{C—H}) + D(\text{Cl—Cl})] - [D(\text{C—Cl}) + D(\text{H—Cl})]$$
$$\Delta H_{\text{rxn}} = (413\text{ kJ} + 242\text{ kJ}) - (328\text{ kJ} + 431\text{ kJ}) = -104\text{ kJ}$$

The reaction is exothermic because the bonds in the products are stronger than the bond in the reactants.

Typically, bond enthalpies are used to estimate ΔH_{rxn} only if the needed ΔH_f° values are not readily available. For the preceding reaction, we cannot calculate ΔH_{rxn} from ΔH_f° values and Hess's law because ΔH_f° for $CH_3Cl(g)$ is not given in Appendix C. If we obtain the value of ΔH_f° for $CH_3Cl(g)$ from another source and use Equation 5.31, we find that $\Delta H_{\text{rxn}} = -99.8$ kJ for the reaction in Equation 5.33. The two values are slightly different because bond enthalpies are averaged over many compounds, but the use of average bond enthalpies provides a reasonably accurate estimate of the actual reaction enthalpy change.

It is important to remember that bond enthalpies are derived for *gaseous* molecules and that they are often *averaged* values. We will always get more precise enthalpies of reaction by using the ΔH_f° values if they are available. Nevertheless, average bond enthalpies are useful for obtaining quick estimates of reaction enthalpies for gas-phase reactions. In solids, liquids, and solutions, intermolecular forces between different molecules must also be taken into account, as we discuss in Chapter 11. For now it is sufficient to remember that bond enthalpies should not generally be used to estimate the enthalpies of reactions involving solids, liquids, or solutions.

Go Figure Is this reaction exothermic or endothermic?

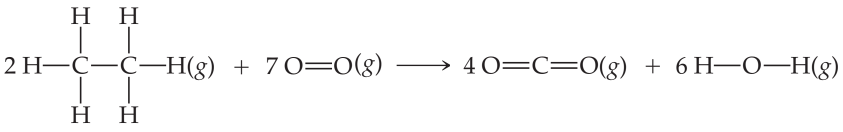


▲ **Figure 5.24 Using bond enthalpies to estimate ΔH_{rxn}.** Average bond enthalpies are used to estimate ΔH_{rxn} for the reaction of methane with chlorine to make methyl chloride and hydrogen chloride.

Sample Exercise 5.12

Estimating Reaction Enthalpies from Bond Enthalpies

Use Table 5.4 to estimate ΔH for the following combustion reaction.



$$2\,\text{H—}\underset{\text{H}}{\overset{\text{H}}{\text{C}}}\text{—}\underset{\text{H}}{\overset{\text{H}}{\text{C}}}\text{—H}(g) + 7\,\text{O=O}(g) \longrightarrow 4\,\text{O=C=O}(g) + 6\,\text{H—O—H}(g)$$

SOLUTION

Analyze We are asked to use average bond enthalpies to estimate the enthalpy change for a chemical reaction.

Plan Energy is required to break twelve C—H bonds and two C—C bonds in the two molecules of C_2H_6, and seven O=O bonds in the seven O_2 molecules. Energy is released by forming eight C=O bonds (two for each of the four molecules of CO_2), and twelve O—H bonds (two per H_2O molecule).

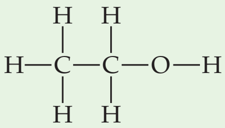
Solve Using Equation 5.32 and data from Table 5.4, we have

$$\begin{aligned}\Delta H &= [12D(\text{C—H}) + 2D(\text{C—C}) + 7D(\text{O=O})] \\ &\quad - [8D(\text{C=O}) + 12D(\text{O—H})] \\ &= [12(413\text{ kJ}) + 2(348\text{ kJ}) + 7(495\text{ kJ})] \\ &\quad - [8(799\text{ kJ}) + 12(463\text{ kJ})] \\ &= 9117\text{ kJ} - 11948\text{ kJ} \\ &= -2831\text{ kJ}\end{aligned}$$

Check This estimate can be compared with the value of −2856 kJ calculated from more accurate thermochemical data; the agreement is good.

▶ **Practice Exercise**

Use the average bond enthalpies in Table 5.4 to estimate ΔH for the combustion of ethanol.



$$\text{H—}\underset{\text{H}}{\overset{\text{H}}{\text{C}}}\text{—}\underset{\text{H}}{\overset{\text{H}}{\text{C}}}\text{—O—H}$$

Self-Assessment Exercises

SAE 5.21 Molecules of gaseous hypobromous acid, HOBr(*g*), have one H—O bond and one O—Br bond:

$$\mathrm{H{-}O{-}Br}$$

HOBr can react with H_2 in the gas phase to form H_2O and HBr:

$$\mathrm{HOBr}(g) + \mathrm{H_2}(g) \rightarrow \mathrm{H_2O}(g) + \mathrm{HBr}(g) \quad \Delta H = -216\ \mathrm{kJ}$$

Using this equation and the data in Table 5.4, determine a value for the bond enthalpy of the O—Br bond in HOBr. (**a**) 177 kJ/mol (**b**) 393 kJ/mol (**c**) 613 kJ/mol (**d**) 640 kJ/mol

SAE 5.22 Consider the hypothetical reaction between two diatomic molecules in the gas phase:

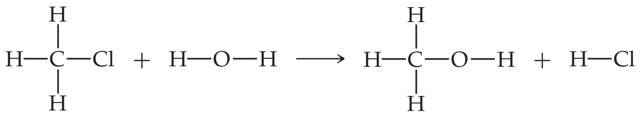
$$\mathrm{X{-}X}\ (g) + \mathrm{Y{-}Y}\ (g) \longrightarrow 2\ \mathrm{X{-}Y}\ (g)$$

Based on the bond enthalpies in Table 5.4, how many of the following combinations of X and Y are predicted to lead to exothermic reactions?

(**i**) X = H, Y = F
(**ii**) X = H, Y = Br
(**iii**) X = F, Y = Cl
(**iv**) X = Cl, Y = I

(**a**) 0 combinations will lead to an exothermic reaction. (**b**) 1 (**c**) 2 (**d**) 3 (**e**) 4

SAE 5.23 Consider the reaction between chloromethane (CH_3Cl) and water in the gas phase to form methanol (CH_3OH) and hydrogen chloride:



$$\mathrm{H{-}\overset{H}{\underset{H}{C}}{-}Cl + H{-}O{-}H \longrightarrow H{-}\overset{H}{\underset{H}{C}}{-}O{-}H + H{-}Cl}$$

Using the bond enthalpy data in Table 5.4, estimate the enthalpy change for this reaction. (**a**) −461 kJ (**b**) −439 kJ (**c**) +2 kJ (**d**) +465 kJ

5.9 | Foods and Fuels

Learning Objectives

When you finish Section 5.9, you should be able to:

- Estimate the amount of energy released when a particular food is metabolized.
- Estimate the amount of energy released by the combustion of particular fuels.

We finish this chapter with a brief discussion of two practical ways chemical energy affects our daily lives: the energy we obtain from the food we eat, and the energy derived from the fuels used to generate electricity, heat, and transportation. We will see that most of the chemical reactions used for the production of energy are controlled or uncontrolled combustion reactions.

The energy released when one gram of any substance is combusted is the **fuel value** of the substance. The fuel value of any food or fuel can be measured by calorimetry. (Section 5.5)

Foods

Most of the energy our bodies need comes from carbohydrates and fats. The carbohydrates known as starches are decomposed in the intestines into glucose, $C_6H_{12}O_6$. Glucose is soluble in blood, and in the human body it is known as blood sugar. It is transported by the blood to cells where it reacts with O_2 in a series of steps, eventually producing $CO_2(g)$, $H_2O(l)$, and energy:

$$\mathrm{C_6H_{12}O_6}(s) + 6\,\mathrm{O_2}(g) \longrightarrow 6\,\mathrm{CO_2}(g) + 6\,\mathrm{H_2O}(l) \qquad \Delta H^\circ = -2803\ \mathrm{kJ}$$

Notice that the products of this reaction (and others we see for foods) are associated with combustion reactions. (Section 3.2) Living organisms obtain energy by controlling these combustion reactions, via their metabolism, to release energy in small steps, which is more efficient and controllable.

When we discuss the fuel value of foods, we often use not only the unit of kJ but also kcal and the common unit of Calories (1 Cal = 1000 cal = 1 kcal). (Section 1.5) In the discussion that follows, we give fuel values in both kJ and kcal.

Because carbohydrates break down rapidly, their energy is quickly supplied to the body. However, the body stores only a very small amount of carbohydrates. The average fuel value of carbohydrates is 17 kJ/g (4 kcal/g). Although fuel values represent the heat released in a combustion reaction, by convention fuel values are reported as positive numbers.

Like carbohydrates, fats react with O_2 to produce CO_2 and H_2O when metabolized. The reaction of tristearin, $C_{57}H_{110}O_6$, a typical fat, is

$$2\,C_{57}H_{110}O_6(s) + 163\,O_2(g) \longrightarrow 114\,CO_2(g) + 110\,H_2O(l) \qquad \Delta H^\circ = -71{,}609\ \text{kJ}$$

The body uses the chemical energy from foods to maintain body temperature (see the "Chemistry and Life" box in Section 5.5), to contract muscles, and to construct and repair tissues. Any excess energy is stored as fats. Fats are well suited to serve as the body's energy reserve for at least two reasons: (1) They are insoluble in water, which facilitates storage in the body, and (2) they produce more energy per gram than either proteins or carbohydrates, which makes them efficient energy sources on a mass basis. The average fuel value of fats is 38 kJ/g (9 kcal/g).

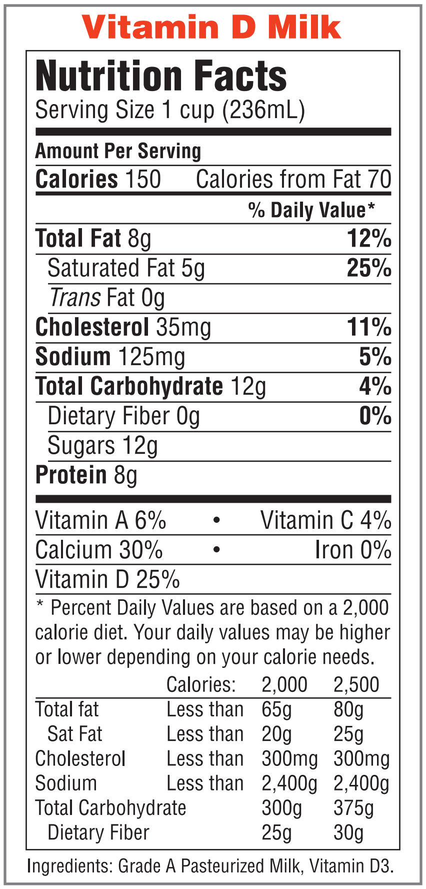
The combustion of carbohydrates and fats in a bomb calorimeter gives the same products as when they are metabolized in the body. The metabolism of proteins produces less energy than combustion in a calorimeter because the products are different. Proteins contain nitrogen, which is released in the bomb calorimeter as N_2. In the body this nitrogen ends up mainly as urea, $(NH_2)_2CO$. The body uses proteins mainly as building materials for organ walls, skin, hair, muscle, and so forth. On average, the metabolism of proteins produces 17 kJ/g (4 kcal/g), the same as for carbohydrates.

Fuel values for some common foods are listed in **Table 5.5**. Labels on packaged foods show the amounts of carbohydrate, fat, and protein contained in an average serving, as well as the amount of energy supplied by a serving (**Figure 5.25**).

The amount of energy our bodies require varies considerably, depending on such factors as weight, age, and muscular activity. About 100 kJ per kilogram of body mass per day is required to keep the body functioning at a minimal level. An average 70-kg (154-lb) person expends about 800 kJ/h when doing light work, and strenuous activity often requires 2000 kJ/h or more. When the fuel value, or caloric content, of the food we ingest exceeds the energy we expend, our body stores the surplus as fat.

Go Figure

Which value would change most if this label were for skim milk instead of whole milk: grams of fat, grams of total carbohydrate, or grams of protein?



Vitamin D Milk

[a] Beer typically contains 3.5% ethanol, which has fuel value.

Sample Exercise 5.13

Estimating the Fuel Value of a Food from Its Composition

(**a**) A 28-g (1-oz) serving of a popular breakfast cereal served with 120 mL of skim milk provides 8 g protein, 26 g carbohydrates, and 2 g fat. Using the average fuel values of these substances, estimate the fuel value (caloric content) of this serving.
(**b**) A person of average weight uses about 100 Cal/mi when running or jogging. How many servings of this cereal provide the fuel value requirements to run 3 mi?

SOLUTION

Analyze (**a**) The fuel value of the serving will be the sum of the fuel values of the protein, carbohydrates, and fat. (**b**) Here we are faced with the reverse problem, calculating the quantity of food that provides a specific fuel value.

Plan (**a**) We are given the masses of the protein, carbohydrates, and fat contained in a serving. We can use the data in Table 5.4 to convert these masses to their fuel values, which we can sum to get the total fuel value. (**b**) The problem statement provides a conversion factor between Calories and miles. The answer to part (**a**) provides us with a conversion factor between servings and Calories.

Solve

(**a**)

$$(8\ \cancel{\text{g protein}})\left(\frac{17\ \text{kJ}}{1\ \cancel{\text{g protein}}}\right) + (26\ \cancel{\text{g carbohydrate}})\left(\frac{17\ \text{kJ}}{1\ \cancel{\text{g carbohydrate}}}\right)$$

$$+ (2\ \cancel{\text{g fat}})\left(\frac{38\ \text{kJ}}{1\ \cancel{\text{g fat}}}\right) = 650\ \text{kJ (two significant figures)}$$

This corresponds to 160 kcal:

$$(650\ \cancel{\text{kJ}})\left(\frac{1\ \text{kcal}}{4.18\ \cancel{\text{kJ}}}\right) = 160\ \text{kcal}$$

The dietary Calorie is equivalent to 1 kcal, so the serving provides 160 Cal.

(**b**) We can use these factors in a straightforward dimensional analysis to determine the number of servings needed, rounded to the nearest whole number:

$$\text{Servings} = (3\ \cancel{\text{mi}})\left(\frac{100\ \cancel{\text{Cal}}}{1\ \cancel{\text{mi}}}\right)\left(\frac{1\ \text{serving}}{160\ \cancel{\text{Cal}}}\right) = 2\ \text{servings}$$

Practice Exercise

(**a**) Dry red beans contain 62% carbohydrate, 22% protein, and 1.5% fat. Estimate the fuel value of these beans. (**b**) During a very light activity, such as reading or watching television, the average adult expends about 7 kJ/min. How many minutes of such activity can be sustained by the energy provided by a serving of chicken noodle soup containing 13 g protein, 15 g carbohydrate, and 5 g fat?

Fuels

During the complete combustion of fuels, carbon is converted to CO_2 and hydrogen is converted to H_2O, both of which have large negative enthalpies of formation. Consequently, the greater the percentage of carbon and hydrogen in a fuel, the higher its fuel value. Using **Table 5.6**, for example, compare the compositions and fuel values of bituminous coal and wood. The coal has a higher fuel value because of its greater carbon content.

In 2019 the United States consumed 1.06×10^{17} kJ of energy. This value corresponds to an average daily energy consumption per person of 8.8×10^5 kJ, roughly 100 times greater than the per capita food-energy needs. **Figure 5.26** illustrates the sources of this energy.

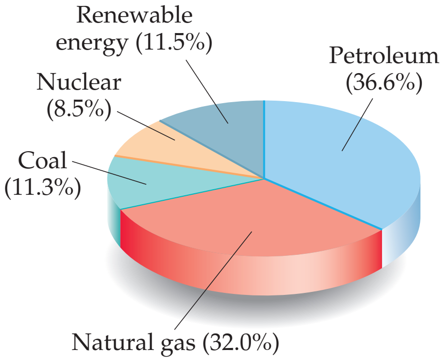
Coal, petroleum, and natural gas, which are the world's major sources of energy, are known as **fossil fuels**. All have formed over millions of years from the decomposition of plants and animals and are being depleted far more rapidly than they are being formed.

Natural gas consists of gaseous hydrocarbons, which are compounds of hydrogen and carbon. It contains primarily methane (CH_4), with small amounts of ethane (C_2H_6), propane (C_3H_8), and butane (C_4H_{10}). We determined the fuel value of propane in Sample Exercise 5.10. Natural gas burns with far fewer by-products and produces less CO_2 than either petroleum or coal. **Petroleum** is a liquid composed of hundreds of compounds, most of which are hydrocarbons, with the remainder being chiefly organic compounds containing sulfur, nitrogen, or oxygen. **Coal**, which is solid, contains hydrocarbons of high molecular weight as well as compounds containing sulfur, oxygen, or nitrogen. Coal is the most abundant fossil fuel; current reserves are projected to last for well over 100 years at current consumption rates. However, the use of coal presents a number of problems.

Coal is a complex mixture of substances, and some of its components cause air pollution. When coal is combusted, the sulfur it contains is converted mainly to sulfur dioxide,

TABLE 5.6 Fuel Values and Compositions of Some Common Fuels

	Approximate Elemental Composition (Mass %)			
	C	H	O	Fuel Value (kJ/g)
Wood (pine)	50	6	44	18
Anthracite coal (Pennsylvania)	82	1	2	31
Bituminous coal (Pennsylvania)	77	5	7	32
Charcoal	100	0	0	34
Crude oil (Texas)	85	12	0	45
Gasoline	85	15	0	48
Natural gas	70	23	0	49
Hydrogen	0	100	0	142



▲ **Figure 5.26 Energy consumption in the United States.*** In 2019 the United States consumed a total of 1.06×10^{17} kJ of energy.

SO_2, a troublesome air pollutant. Because coal is a solid, recovery from its underground deposits is expensive and often dangerous. Furthermore, coal deposits are not always close to locations of high-energy use, so there are often substantial shipping costs. U.S. dependence on coal as a primary energy source declined by roughly 5% from 2015 to 2019.

Fossil fuels release energy in combustion reactions, which ideally produce only CO_2 and H_2O. The production of CO_2 has become a major issue for science and public policy because of concerns that increasing concentrations of atmospheric CO_2 are causing global climate changes. We discuss the environmental aspects of atmospheric CO_2 in Chapter 18.

Other Energy Sources

Nuclear energy is the energy released in either the fission (splitting) or the fusion (combining) of atomic nuclei. Nuclear power based on nuclear fission currently produces about 19% of electric power in the United States and makes up about 8.5% of total U.S. energy production (Figure 5.26). On the one hand, nuclear energy is, in principle, free of the polluting emissions that are a major problem with fossil fuels. On the other hand, nuclear power plants produce radioactive waste products, and their use has therefore been controversial. We discuss issues related to the production of nuclear energy in Chapter 21.

Fossil fuels and nuclear energy are *nonrenewable* sources of energy: They are limited resources that we are consuming at a much greater rate than they can be regenerated. Eventually, these fuels will be expended, although estimates vary greatly as to when this will occur. Because nonrenewable energy sources will eventually be used up, a great deal of research is being conducted on **renewable energy sources**, that is, sources that are essentially inexhaustible. Renewable energy sources include *solar energy* from the Sun, *wind energy* harnessed by windmills, *geothermal energy* from the heat stored inside Earth, *hydroelectric energy* from flowing rivers, and *biomass energy* from crops and biological waste matter. Currently, renewable sources account for about 11.5% of the U.S. annual energy consumption. Electricity is typically generated by using a moving gas or liquid to turn a turbine that is connected to a generator, although there are some exceptions like solar cells. Of the 3.9×10^{16} kJ of electricity consumed in 2019 in the United States, approximately 62% came from burning fossil fuels. Other sources of electricity include nuclear energy (19%), hydroelectric power (6.8%), wind (7.1%), biomass (1.4%) and solar energy (2.6%).

Fulfilling our future energy needs will depend on developing the technology to harness solar energy with greater efficiency. Solar energy is the world's largest energy source. On a clear day, about 1 kJ of solar energy reaches each square meter of Earth's surface every second. The average solar energy falling on only 0.1% of U.S. land area is equivalent to all the energy this nation currently uses. Harnessing this energy is difficult because it is dilute (that is, distributed over a wide area) and varies with time of day and weather conditions. The effective use of solar energy will depend on the development of some means of storing and distributing it. One practical way to do this is to use the Sun's energy to drive an endothermic chemical process that can be later reversed to release heat. One such reaction is

---

*"U.S. energy facts explained," U.S Energy Information Administration, U.S. Department of Energy, EIA.gov.

$$CH_4(g) + H_2O(g) + \text{heat} \longrightarrow CO(g) + 3\,H_2(g)$$

This reaction proceeds in the forward direction at high temperatures, which can be obtained in a solar furnace. The CO and H_2 formed in the reaction could then be stored and allowed to react later, with the heat released being put to useful work.

CHEMISTRY AND SUSTAINABILITY The Scientific and Political Challenges of Biofuels

One of the biggest challenges facing us in the twenty-first century is production of abundant sources of energy, both food and fuels. At the end of 2019, the global population was estimated to be 7.7 billion and growing at a rate of about 840 million per decade. A growing world population puts greater demands on the global food supply, especially in Asia and Africa, which together make up more than 76% of the world population.

A growing population also increases demands on the production of fuels for transportation, industry, electricity, heating, and cooling. As populous countries such as China and India have modernized, their per capita consumption of energy has increased significantly. In China, for instance, per capita energy consumption roughly doubled between 1990 and 2010, and in 2010 China passed the United States as the world's largest user of energy (although China's per capita consumption is still less than 35% of the U.S. figure).

Global energy consumption in 2019 was more than 4×10^{18} kJ, a staggeringly large number. More than 86% of current energy requirements comes from combustion of nonrenewable fossil fuels (petroleum, coal, and natural gas). The exploration of new fossil fuel sources often involves environmentally sensitive regions, making the search for new supplies of fossil fuels a major political and economic issue.

Petroleum has global importance largely because it provides liquid fuels, such as gasoline, that are critical to supplying transportation needs. One of the most promising—but controversial—alternatives to petroleum-based fuels is *biofuels*, liquid fuels derived from biological matter. The most common approach to producing biofuels is to transform plant sugars and other carbohydrates into combustible liquids.

The most commonly produced biofuel is *bioethanol*, which is ethanol (C_2H_5OH) made from fermentation of plant carbohydrates. The fuel value of ethanol is about two-thirds that of gasoline and is therefore comparable to that of coal (Table 5.6). The United States and Brazil dominate bioethanol production, together supplying 85% of the world's total.

In the United States, nearly all the bioethanol currently produced is made from yellow feed corn. Yeasts or other microorganisms are used to convert glucose ($C_6H_{12}O_6$) in the corn to ethanol and CO_2:

$$C_6H_{12}O_6(s) \longrightarrow 2\,C_2H_5OH(l) + 2\,CO_2(g) \qquad \Delta H = 15.8\text{ kJ}$$

This reaction is *anaerobic*—it does not involve $O_2(g)$—and the enthalpy change is positive and much smaller in magnitude than that for most combustion reactions. Other carbohydrates can be converted to ethanol in similar fashion. Because the carbon in growing plants comes from CO_2 in the air via photosynthesis, bioethanol contributes considerably less net CO_2 to the atmosphere and is therefore a more sustainable source of energy than are fossil fuels.

Producing bioethanol from corn is controversial for two main reasons. First, growing and transporting corn are both energy-intensive processes, and growing it requires the use of fertilizers. It is estimated that the *energy return* on corn-based bioethanol is only 34%—that is, for each 1.00 J of energy expended to produce the corn, 1.34 J of energy is produced in the form of bioethanol. Second, the use of corn as a starting material for making bioethanol competes with its use as an important component of the food chain (the so-called *food versus fuel* debate).

▲ **Figure 5.27** **Sugarcane can be converted to a sustainable bioethanol product.**

Much current research focuses on the formation of bioethanol from *cellulosic* plants, plants that contain the complex carbohydrate cellulose. Cellulose is not readily metabolized and so does not compete with the food supply. However, the chemistry for converting cellulose to ethanol is much more complex than that for converting corn. Cellulosic bioethanol could be produced from very fast-growing nonfood plants, such as prairie grasses and switchgrass, which readily renew themselves without the use of fertilizers.

The Brazilian bioethanol industry uses sugarcane as its feedstock (**Figure 5.27**). Sugarcane grows much faster than corn and needs neither fertilizers nor tending. Because of these differences, the energy return for sugarcane is much higher than that for corn. It is estimated that for each 1.0 J of energy expended in growing and processing sugarcane, 8.0 J of energy is produced as bioethanol. In 2019, Brazil produced more than 8600 million U.S. gallons of bioethanol.

While bioethanol is a sustainable fuel source, Brazil's expansion of the sugarcane industry has threatened environmentally sensitive regions, including the Amazon rainforest, via deforestation. These rainforests are among the most important ways in which the Earth reabsorbs the CO_2 that contributes to climate change. Thus, even as we develop ways to make certain aspects of our lives more sustainable, we must consider unintended consequences that adversely impact other areas of sustainability.

Other biofuels that are becoming a major part of the world economy include *biodiesel*, a substitute for petroleum-derived diesel fuel. Biodiesel is typically produced from crops that have a high oil content, such as soybeans and canola. It can also be produced from animal fats and waste vegetable oil from the food and restaurant industry.

Related Exercises: 5.99, 5.100, 5.120

Plants utilize solar energy in *photosynthesis*, the reaction in which the energy of sunlight is used to convert CO_2 and H_2O into carbohydrates and O_2:

$$6\,CO_2(g) + 6\,H_2O(l) + \text{sunlight} \longrightarrow C_6H_{12}O_6(s) + 6\,O_2(g) \qquad [5.34]$$

Photosynthesis is an important part of Earth's ecosystem because it replenishes atmospheric O_2, produces an energy-rich molecule that can be used as fuel, and consumes some atmospheric CO_2.

Perhaps the most direct way to use the Sun's energy is to convert it directly into electricity in photovoltaic devices, or *solar cells*, which we mentioned at the beginning of this chapter. The efficiencies of such devices have increased dramatically during the past few years. Technological advances have led to solar panels that last longer and produce electricity with greater efficiency at steadily decreasing unit cost. Indeed, the future of solar energy is, like the Sun itself, very bright.

Self-Assessment Exercises

Here are a few problems designed to test your understanding of the material.

SAE 5.24 A tablespoon of granulated table sugar contains 12.5 g of sucrose ($C_{12}H_{22}O_{11}$). The balanced reaction for the combustion of sucrose to $CO_2(g)$ and $H_2O(l)$ is:

$$C_{12}H_{22}O_{11}(s) + 12\,O_2(g) \rightarrow 12\,CO_2(g) + 11\,H_2O(l) \quad \Delta H = -5640\text{ kJ}$$

If we assume that the metabolism of sucrose leads to the same amount of heat as in the preceding equation, how many Calories are provided by complete metabolism of a tablespoon of sucrose? (**a**) 3.94 Cal (**b**) 49.3 Cal (**c**) 206 Cal (**d**) 1350 Cal

SAE 5.25 One component of biodiesel is a substance derived from fatty acids, called *ethyl stearate*. The formula of ethyl stearate is $C_{20}H_{40}O_2$, and ΔH for the combustion of 1.50 mol of the substance is $-18{,}900$ kJ. What is the fuel value in kJ/g of ethyl stearate? (**a**) 40.3 (**b**) 60.5 (**c**) 90.7 (**d**) 12,600

Putting Concepts Together

Trinitroglycerin, $C_3H_5N_3O_9$ (usually referred to simply as nitroglycerin), has been widely used as an explosive. Alfred Nobel used it to make dynamite in 1866. Rather surprisingly, it also is used as a medication, to relieve angina (chest pains resulting from partially blocked arteries to the heart) by dilating the blood vessels. At 1 atm pressure and 25°C, the enthalpy of decomposition of trinitroglycerin to form nitrogen gas, carbon dioxide gas, liquid water, and oxygen gas is -1541.4 kJ/mol.

(a) Write a balanced chemical equation for the decomposition of trinitroglycerin.

(b) Calculate the standard heat of formation of trinitroglycerin.

(c) A standard dose of trinitroglycerin for relief of angina is 0.60 mg. If the sample is eventually oxidized in the body (not explosively, though!) to nitrogen gas, carbon dioxide gas, and liquid water, what number of calories is released?

(d) One common form of trinitroglycerin melts at about 3°C. From this information and the formula for the substance, would you expect it to be a molecular or an ionic compound? Explain.

(e) Describe the various conversions of forms of energy when trinitroglycerin is used as an explosive to break rockfaces in highway construction.

SOLUTION

(**a**) The general form of the equation we must balance is

$$C_3H_5N_3O_9(l) \longrightarrow N_2(g) + CO_2(g) + H_2O(l) + O_2(g)$$

We go about balancing in the usual way. To obtain an even number of nitrogen atoms on the left, we multiply the formula for $C_3H_5N_3O_9$ by 2, which gives us 3 mol of N_2, 6 mol of CO_2 and 5 mol of H_2O. Everything is then balanced except for oxygen. We have an odd number of oxygen atoms on the right. We can balance the oxygen by using the coefficient $\frac{1}{2}$ for O_2 on the right:

$$2\,C_3H_5N_3O_9(l) \longrightarrow 3\,N_2(g) + 6\,CO_2(g) + 5\,H_2O(l) + \tfrac{1}{2}O_2(g)$$

We multiply through by 2 to convert all coefficients to whole numbers:

$$4\,C_3H_5N_3O_9(l) \longrightarrow 6\,N_2(g) + 12\,CO_2(g) + 10\,H_2O(l) + O_2(g)$$

(At the temperature of the explosion, water is a gas rather than a liquid, as shown in the preceding equation. The rapid expansion of the gaseous products creates the force of an explosion.)

Continued

(**b**) We can obtain the standard enthalpy of formation of nitroglycerin by using the heat of decomposition of trinitroglycerin, together with the standard enthalpies of formation of the other substances in the decomposition equation:

$$4\,C_3H_5N_3O_9(l) \longrightarrow 6\,N_2(g) + 12\,CO_2(g) + 10\,H_2O(l) + O_2(g)$$

The enthalpy change for this decomposition is $4(-1541.4\text{ kJ}) = -6165.6\text{ kJ}$. [We need to multiply by 4 because there are 4 mol of $C_3H_5N_3O_9(l)$ in the balanced equation.]

This enthalpy change equals the sum of the heats of formation of the products minus the heats of formation of the reactants, each multiplied by its coefficient in the balanced equation:

$$\begin{aligned}-6165.6\text{ kJ} = {}& 6\Delta H_f^\circ[N_2(g)] + 12\,\Delta H_f^\circ[CO_2(g)] + 10\Delta H_f^\circ[H_2O(l)] \\ & + \Delta H_f^\circ[O_2(g)] - 4\Delta H_f^\circ[C_3H_5N_3O_9(l)]\end{aligned}$$

The ΔH_f° values for $N_2(g)$ and $O_2(g)$ are zero, by definition. Using the values for $H_2O(l)$ and $CO_2(g)$ from Table 5.3 or Appendix C, we have

$$-6165.6\text{ kJ} = 12(-393.5\text{ kJ}) + 10(-285.8\text{ kJ}) - 4\Delta H_f^\circ[C_3H_5N_3O_9(l)]$$

$$\Delta H_f^\circ[C_3H_5N_3O_9(l)] = -353.6\text{ kJ/mol}$$

(**c**) Converting 0.60 mg $C_3H_5N_3O_9(l)$ to moles and using the fact that the decomposition of 1 mol of $C_3H_5N_3O_9(l)$ yields 1541.4 kJ, we have:

$$(0.60 \times 10^{-3}\text{ g } C_3H_5N_3O_9)\left(\frac{\cancel{1\text{ mol } C_3H_5N_3O_9}}{227\text{ g } C_3H_5N_3O_9}\right)\left(\frac{1541.4\text{ kJ}}{\cancel{1\text{ mol } C_3H_5N_3O_9}}\right)$$

$$= 4.1 \times 10^{-3}\text{ kJ} = 4.1\text{ J}$$

(**d**) Because trinitroglycerin melts below room temperature, we expect that it is a molecular compound. With few exceptions, ionic substances are generally hard, crystalline materials that melt at high temperatures. (Sections 2.6 and 2.7) Also, the molecular formula suggests that it is a molecular substance because all of its constituent elements are nonmetals.

(**e**) The energy stored in trinitroglycerin is chemical potential energy. When the substance reacts explosively, it forms carbon dioxide, water, and nitrogen gas, which are of lower potential energy. In the course of the chemical transformation, energy is released in the form of heat; the gaseous reaction products are very hot. This high heat energy is transferred to the surroundings. Work is done as the gases expand against the surroundings, moving the solid materials and imparting kinetic energy to them. For example, a chunk of rock might be impelled upward. It has been given kinetic energy by transfer of energy from the hot, expanding gases. As the rock rises, its kinetic energy is transformed into potential energy. Eventually, it again acquires kinetic energy as it falls to Earth. When it strikes Earth, its kinetic energy is converted largely to thermal energy, though some work may be done on the surroundings as well.

Chapter Summary and Key Terms

CHEMICAL ENERGY (INTRODUCTION AND SECTION 5.1)

Thermodynamics is the study of energy and its transformations. In this chapter we have focused on **thermochemistry**, the transformation of energy—especially heat—during chemical reactions.

An object can possess energy in two forms: (1) **kinetic energy**, which is the energy due to the motion of the object, and (2) **potential energy**, which is the energy that an object possesses by virtue of its position relative to other objects. An electron in motion near a proton has kinetic energy because of its motion and potential energy owing to its electrostatic attraction to the proton.

Chemical energy originates largely from electrostatic interactions at the atomic level. Energy must be supplied to break chemical bonds leading to an increase in potential energy. Conversely, energy is released when chemical bonds form as the potential energy decreases.

THE FIRST LAW OF THERMODYNAMICS (SECTION 5.2) When we study thermodynamic properties, we define a specific amount of matter as the **system**. Everything outside the system is the **surroundings**. When we study a chemical reaction, the system is generally the reactants and products. A closed system can exchange energy, but not matter, with the surroundings. The **internal energy** of a system is the sum of all the kinetic and potential energies of its component parts. The internal energy of a system can change because of energy transferred between the system and the surroundings.

According to the **first law of thermodynamics**, the change in the internal energy of a system, ΔE, is the sum of the heat, q, transferred into or out of the system and the work, w, done on or by the system: $\Delta E = q + w$. Both q and w have a sign that indicates the direction of energy transfer. When heat is transferred from the surroundings to the system, $q > 0$. Likewise, when the surroundings do work on the system, $w > 0$. In an **endothermic** process, the system absorbs heat from the surroundings; in an **exothermic** process, the system releases heat to the surroundings.

The internal energy, E, is a **state function**. The value of any state function depends only on the state or condition of the system and not on the details of how it came to be in that state. Heat, q, and work, w, are not state functions; their values depend on the particular way by which a system changes its state.

ENTHALPY (SECTIONS 5.3 AND 5.4) When a gas is produced or consumed in a chemical reaction occurring at constant pressure, the system may perform **pressure–volume (*P–V*) work** against the prevailing pressure of the surroundings. For this reason, we define a new state function called **enthalpy**, H, which is related to energy: $H = E + PV$. In systems where only pressure–volume work is involved, the change in the enthalpy of a system, ΔH, equals the heat gained or lost by the system at constant pressure: $\Delta H = q_p$ (the subscript P denotes constant pressure). For an endothermic process, $\Delta H > 0$; for an exothermic process, $\Delta H < 0$.

In a chemical process, the **enthalpy of reaction** is the enthalpy of the products minus the enthalpy of the reactants: $\Delta H_{\text{rxn}} = H(\text{products}) - H(\text{reactants})$. Enthalpies of reaction follow some simple rules: (1) The enthalpy of reaction is proportional to the amount of reactant that reacts. (2) Reversing a reaction changes the sign of ΔH. (3) The enthalpy of reaction depends on the physical states of the reactants and products.

CALORIMETRY (SECTION 5.5) The amount of heat transferred between the system and the surroundings is measured experimentally by **calorimetry**. A **calorimeter** measures the temperature change accompanying a process. The temperature change of a calorimeter depends on its **heat capacity**, the amount of heat required to raise its temperature by 1 K. The heat capacity for one mole of a pure substance is called its **molar heat capacity**; for one gram of the substance, we use the term **specific heat**. Water has a very high specific heat, 4.18 J/g-K. The amount of heat, q, absorbed by a substance is the product of its specific heat (C_s), its mass, and its temperature change: $q = C_s \times m \times \Delta T$.

If a calorimetry experiment is carried out under a constant pressure, the heat transferred provides a direct measure of the enthalpy change of the reaction. Constant-volume calorimetry is carried out in a vessel of fixed volume called a **bomb calorimeter**. The heat transferred under constant-volume conditions is equal to ΔE. Corrections can be applied to ΔE values to yield ΔH.

HESS'S LAW (SECTION 5.6) Because enthalpy is a state function, ΔH depends only on the initial and final states of the system. Thus, the enthalpy change of a process is the same whether the process is carried out in one step or in a series of steps. **Hess's law** states that if a reaction is carried out in a series of steps, ΔH for the reaction will be equal to the sum of the enthalpy changes for the steps. We can therefore calculate ΔH for any process, as long as we can write the process as a series of steps for which ΔH is known.

ENTHALPIES OF FORMATION (SECTION 5.7) The **enthalpy of formation**, ΔH_f, of a substance is the enthalpy change for the reaction in which the substance is formed from its constituent elements. Usually, enthalpies are tabulated for reactions where reactants and products are in their *standard states*. The standard state of a substance is its pure, most stable form at 1 atm and the temperature of interest (usually 298 K). Thus, the **standard enthalpy change** of a reaction, ΔH°, is the enthalpy change when all reactants and products are in their standard states. The **standard enthalpy of formation**, ΔH_f°, of a substance is the change in enthalpy for the reaction that forms one mole of the substance from its elements in their standard states. For any element in its standard state, $\Delta H_f^\circ = 0$.

The standard enthalpy change for any reaction can be readily calculated from the standard enthalpies of formation of the reactants and products in the reaction:

$$\Delta H^\circ_{\text{rxn}} = \sum n\Delta H_f^\circ(\text{products}) - \sum m\Delta H_f^\circ(\text{reactants})$$

BOND ENTHALPIES (SECTION 5.8) The strength of a covalent bond is measured by its bond enthalpy, which is the molar enthalpy change required to break a particular bond. Average bond enthalpies can be determined for a wide variety of covalent bonds. We can estimate the enthalpy changes during chemical reactions involving gaseous substances by adding the average bond enthalpies of the bonds that are broken and subtracting the average bond enthalpies of the bonds that are formed. When the energy needed to break bonds is larger than the energy released by forming bonds, the reaction enthalpy is positive; when the opposite situation holds, the reaction enthalpy is negative.

FOODS AND FUELS (SECTION 5.9) The **fuel value** of a substance is the heat released when one gram of the substance is combusted. Different types of foods have different fuel values and differing abilities to be stored in the body. The most common fuels are hydrocarbons found as **fossil fuels**, such as **natural gas**, **petroleum**, and **coal**. **Renewable energy sources** include solar energy, wind energy, biomass, and hydroelectric energy. Nuclear power does not utilize fossil fuels but does create controversial waste-disposal problems.

Key Equations

• $w = F \times d$	[5.1]	Relation of work to force and distance
• $E_{\text{el}} = \kappa Q_1Q_2/d$	[5.2]	Electrostatic potential energy
• $\Delta E = E_{\text{final}} - E_{\text{initial}}$	[5.3]	The change in internal energy
• $\Delta E = q + w$	[5.4]	Relation of the change in internal energy to heat and work (the first law of thermodynamics)
• $H = E + PV$	[5.5]	Enthalpy defined
• $w = -P\Delta V$	[5.7]	The work done by an expanding gas at constant pressure
• $\Delta H = \Delta E + P\Delta V = q_P$	[5.9]	Enthalpy change at constant pressure
• $q = C_s \times m \times \Delta T$	[5.21]	Heat gained or lost based on specific heat, mass, and temperature change
• $q_{\text{rxn}} = -C_{\text{cal}} \times \Delta T$	[5.23]	Heat exchanged between a reaction and calorimeter
• $\Delta H^\circ_{\text{rxn}} = \Sigma n\Delta H_f^\circ(\text{products}) - \Sigma m\Delta H_f^\circ(\text{reactants})$	[5.31]	Standard enthalpy change of a reaction
• $\Delta H_{\text{rxn}} = \Sigma\,(\text{bond enthalpies of bonds broken}) - \Sigma\,(\text{bond enthalpies of bonds formed})$	[5.32]	The reaction enthalpy as a function of average bond enthalpies for reactions involving gas-phase molecules.

Exam Prep

EP 5.1 KBr consists of positively charged potassium ions and negatively charged bromide ions. Which one of the following statements is *false*? (**a**) The potassium and bromide ions are attracted to one another. (**b**) Energy must be added to separate the ions from one another. (**c**) The electrostatic potential energy between potassium and bromide ions is positive. (**d**) The strength of the interaction between the potassium and bromide ions depends on the distance between the ions.

EP 5.2 A mixture of gases A_2 and B_2 are introduced to a slender metal cylinder that has one end closed and the other fitted with a piston that makes a gas-tight seal so that the gases are a closed system. The cylinder is submerged in a large beaker of water whose temperature is 25°C, and a spark is used to trigger a reaction in the cylinder. At the completion of the reaction, the piston has moved downward, and the temperature of the water bath has increased to 28°C. If we define the system as the gases inside the cylinder, which of the following best describes the signs of q, w, and ΔE for this reaction? (**a**) $q < 0$, $w < 0$, $\Delta E < 0$ (**b**) $q < 0$, $w > 0$, $\Delta E < 0$ (**c**) $q < 0$, $w > 0$, the sign of ΔE cannot be determined from the information given (**d**) $q > 0$, $w > 0$, $\Delta E > 0$ (**e**) $q > 0$, $w < 0$, the sign of ΔE cannot be determined from the information given

EP 5.3 A system can change from State A to State B using two different paths, Path 1 and Path 2. Which of the following statements is or are *true*?

(**i**) The value of q might be different for the two different paths.

(**ii**) The value of ΔE might be different for the two different paths.

(**iii**) The value of $q + w$ must be the same for the two different paths.

(**a**) Only one of the statements is true. (**b**) i and ii are true. (**c**) i and iii are true. (**d**) ii and iii are true. (**e**) All three statements are true.

EP 5.4 Which of the following statements about enthalpy is *false*? (**a**) Enthalpy is denoted H. (**b**) ΔH equals the heat gained or lost in a process that occurs at constant pressure. (**c**) Because E, P, and V are all state functions, H is also a state function. (**d**) Because ΔH relates to heat, the value of ΔH depends on the path taken between two states. (**e**) Under constant pressure, $\Delta H = \Delta E + P\Delta V$.

EP 5.5 If a balloon is expanded from 0.055 to 1.403 L against an external pressure of 1.02 atm, how many L-atm of work is done? (**a**) −0.056 L-atm (**b**) −1.37 L-atm (**c**) 1.43 L-atm (**d**) 1.49 L-atm (**e**) 139 L-atm

EP 5.6 A chemical reaction that gives off heat to its surroundings is said to be ________ and has a ________ value of ΔH. (**a**) endothermic, positive (**b**) endothermic, negative (**c**) exothermic, positive (**d**) exothermic, negative

EP 5.7 The figure shows an enthalpy diagram for the following hypothetical reaction run under constant pressure:

$$\text{A}(g) + \text{B}(g) \rightarrow \text{C}(g) + \text{D}(g)$$

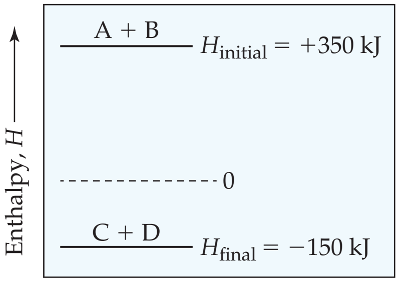
Which of the following statements is or are *true*?

(**i**) The reaction is exothermic.

(**ii**) ΔH for the reaction is −200 kJ.

(**iii**) The reaction is most likely a spontaneous process.

(**a**) Only one of the statements is true. (**b**) i and ii are true. (**c**) i and iii are true. (**d**) ii and iii are true. (**e**) All three statements are true.



EP 5.8 The complete combustion of ethanol, C_2H_5OH (molar mass = 46.0 g/mol), proceeds as follows:

$$C_2H_5OH(l) + 3\,O_2(g) \rightarrow 2\,CO_2(g) + 3\,H_2O(l) \quad \Delta H = -555 \text{ kJ}$$

What is the enthalpy change for combustion of 15.0 g of ethanol? (**a**) −12.1 kJ (**b**) −181 kJ (**c**) −422 kJ (**d**) −555 kJ (**e**) −1700 kJ

EP 5.9 The coinage metals (Group 1B) copper, silver, and gold have specific heats of 0.385, 0.233, and 0.129 J/g-K, respectively. Among this group, the specific heat ________ and the molar heat capacity ________ as the atomic weight increases. (**a**) increases, increases (**b**) increases, decreases (**c**) decreases, increases (**d**) decreases, decreases

EP 5.10 When 0.243 g of Mg metal is combined with enough HCl to make 100 mL of solution in a constant-pressure calorimeter, the following reaction occurs:

$$\text{Mg}(s) + 2\,\text{HCl}(aq) \longrightarrow \text{MgCl}_2(aq) + \text{H}_2(g)$$

If the temperature of the solution increases from 23.0 to 34.1°C as a result of this reaction, calculate ΔH in kJ/mol Mg. Assume that the solution has a specific heat of 4.18 J/g-°C and a density of 1.00 g/mL. (**a**) −19.1 kJ/mol (**b**) −111 kJ/mol (**c**) −191 kJ/mol (**d**) −464 kJ/mol (**e**) −961 kJ/mol

EP 5.11 The combustion of exactly 1.000 g of benzoic acid in a bomb calorimeter releases 26.38 kJ of heat. If the combustion of 0.550 g of benzoic acid causes the temperature of the calorimeter to increase from 22.01 to 24.27 °C, calculate the heat capacity of the calorimeter. (**a**) 0.660 kJ/°C (**b**) 6.42 kJ/°C (**c**) 14.5 kJ/°C (**d**) 21.2 kJ/°C (**e**) 32.7 kJ/°C

EP 5.12 Calculate ΔH for $2\,\text{NO}(g) + \text{O}_2(g) \longrightarrow \text{N}_2\text{O}_4(g)$, using the following information:

$$\text{N}_2\text{O}_4(g) \longrightarrow 2\,\text{NO}_2(g) \quad \Delta H = +57.9 \text{ kJ}$$

$$2\,\text{NO}(g) + \text{O}_2(g) \longrightarrow 2\,\text{NO}_2(g) \quad \Delta H = -113.1 \text{ kJ}$$

(**a**) 2.7 kJ (**b**) −55.2 kJ (**c**) −85.5 kJ (**d**) −171.0 kJ (**e**) +55.2 kJ

EP 5.13 Calculate ΔH for the reaction

$$\text{C}(s) + \text{H}_2\text{O}(g) \longrightarrow \text{CO}(g) + \text{H}_2(g)$$

given the following thermochemical equations:

$$\text{C}(s) + \text{O}_2(g) \longrightarrow \text{CO}_2(g) \quad \Delta H_1 = -393.5 \text{ kJ}$$

$$2\,\text{CO}(g) + \text{O}_2(g) \longrightarrow 2\,\text{CO}_2(g) \quad \Delta H_2 = -566.0 \text{ kJ}$$

$$2\,\text{H}_2(g) + \text{O}_2(g) \longrightarrow 2\,\text{H}_2\text{O}(g) \quad \Delta H_3 = -483.6 \text{ kJ}$$

(**a**) 1443.1 kJ (**b**) 918.3 kJ (**c**) 131.3 kJ (**d**) 262.6 kJ (**e**) 656.1 kJ

EP 5.14 If the heat of formation of $H_2O(l)$ is −286 kJ/mol, which of the following thermochemical equations is correct?

(**a**) $2\,\text{H}(g) + \text{O}(g) \longrightarrow \text{H}_2\text{O}(l) \quad \Delta H = -286 \text{ kJ}$

(**b**) $2\,\text{H}_2(g) + \text{O}_2(g) \longrightarrow 2\,\text{H}_2\text{O}(l) \quad \Delta H = -286 \text{ kJ}$

(**c**) $\text{H}_2(g) + \frac{1}{2}\text{O}_2(g) \longrightarrow \text{H}_2\text{O}(l) \quad \Delta H = -286 \text{ kJ}$

(**d**) $\text{H}_2(g) + \text{O}(g) \longrightarrow \text{H}_2\text{O}(g) \quad \Delta H = -286 \text{ kJ}$

(**e**) $\text{H}_2\text{O}(l) \longrightarrow \text{H}_2(g) + \frac{1}{2}\text{O}_2(g) \quad \Delta H = -286 \text{ kJ}$

EP 5.15 Calculate the enthalpy change for the reaction

$$2\,\text{H}_2\text{O}_2(l) \longrightarrow 2\,\text{H}_2\text{O}(l) + \text{O}_2(g)$$

using the following enthalpies of formation:

$$\Delta H_f^\circ[\text{H}_2\text{O}_2(l)] = -187.8 \text{ kJ/mol} \quad \Delta H_f^\circ[\text{H}_2\text{O}(l)] = -285.8 \text{ kJ/mol}$$

(**a**) −98.0 kJ (**b**) −196.0 kJ (**c**) +98.0 kJ (**d**) +196.0 kJ (**e**) more information needed.

EP 5.16 If $\Delta H_{\text{rxn}}^\circ$ is the enthalpy change for the reaction $2\,\text{SO}_2(g) + \text{O}_2(g) \longrightarrow 2\,\text{SO}_3(g)$, which of the following equations is correct?

(**a**) $\Delta H_f^\circ[\text{SO}_3] = \Delta H_{\text{rxn}}^\circ - \Delta H_f^\circ[\text{SO}_2]$

(**b**) $\Delta H_f^\circ[\text{SO}_3] = \Delta H_{\text{rxn}}^\circ + \Delta H_f^\circ[\text{SO}_2]$

(**c**) $2\Delta H_f^\circ[\text{SO}_3] = \Delta H_{\text{rxn}}^\circ + 2\Delta H_f^\circ[\text{SO}_2]$

(**d**) $2\,\Delta H_f^\circ[\text{SO}_3] = \Delta H_{\text{rxn}}^\circ - 2\,\Delta H_f^\circ[\text{SO}_2]$

(**e**) $2\Delta H_f^\circ[\text{SO}_3] = 2\Delta H_f^\circ[\text{SO}_2] - \Delta H_{\text{rxn}}^\circ$

EP 5.17 Which of the following statements about bond enthalpies is or are *true*?

(**i**) Bond enthalpies are always positive numbers.

(**ii**) The bond enthalpy for a double bond between two atoms is larger than that for a single bond between the same two atoms.

(**iii**) The larger the bond enthalpy, the stronger the bond.

(**a**) Only one of these statements is true. (**b**) i and ii are true. (**c**) i and iii are true. (**d**) ii and iii are true. (**e**) All three statements are true.

EP 5.18 Use the average bond enthalpies in Table 5.4 to estimate ΔH for the "water splitting reaction": $H_2O(g) \longrightarrow H_2(g) + \frac{1}{2}O_2(g)$. (**a**) 242 kJ (**b**) 417 kJ (**c**) 5 kJ (**d**) −5 kJ (**e**) −468 kJ

EP 5.19 A stalk of celery has a caloric content (fuel value) of 9.0 kcal. If 1.0 kcal is provided by fat and there is very little protein, estimate the number of grams of carbohydrate and fat in the celery. (**a**) 2 g carbohydrate and 0.1 g fat (**b**) 2 g carbohydrate and 1 g fat (**c**) 1 g carbohydrate and 2 g fat (**d**) 32 g carbohydrate and 10 g fat

EP 5.20 Liquid methanol $[CH_3OH(l)]$, liquid ethanol $[C_2H_5OH(l)]$, and gaseous dimethyl ether $[CH_3OCH_3(g)]$ are all fuels that contain only carbon, hydrogen, and oxygen atoms. The standard molar enthalpies for combustion of these three fuels to $CO_2(g)$ and $H_2O(g)$ are as follows:

Label	Compound	$\Delta H°_{\text{combustion}}$ (kJ/mol)
A	$CH_3OH(l)$	−638.5
B	$C_2H_5OH(l)$	−1235
C	$CH_3OCH_3(g)$	−1328

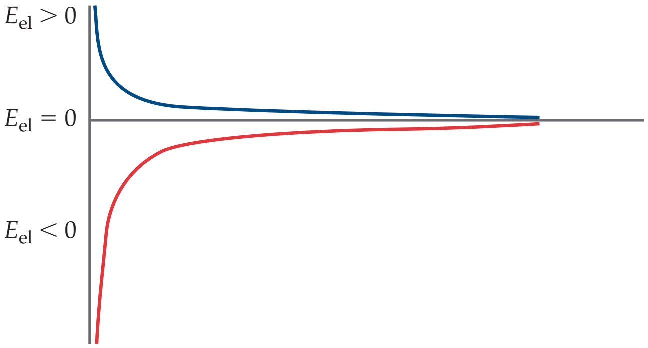
What is the correct order of the three compounds from lowest to highest fuel value in kJ/g? (**a**) A < B < C (**b**) C < B < A (**c**) B < C < A (**d**) A < B = C (**e**) A < C < B

Exercises

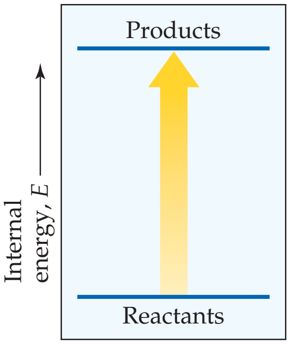
Visualizing Concepts

5.1 The accompanying photo shows a pipevine swallowtail caterpillar climbing up a twig. (**a**) As the caterpillar climbs, its potential energy is increasing. What source of energy has been used to effect this change in potential energy? (**b**) If the caterpillar is the system, can you predict the sign of q as the caterpillar climbs? (**c**) Does the caterpillar do work in climbing the twig? Explain. (**d**) Does the amount of work done in climbing a 12-inch section of the twig depend on the speed of the caterpillar's climb? (**e**) Does the change in potential energy depend on the caterpillar's speed of climb? [Section 5.1]

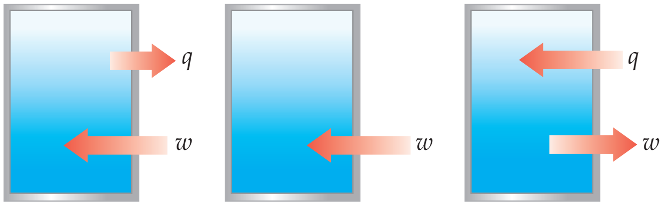
5.2 The blue curve in the plot here shows the potential energy of an ion A interacting with an ion B as a function of their separation distance. The red curve shows the interaction of ion A with a different ion (ion C) as a function of separation. (**a**) Do the charges on ions A and B have the same or different signs? (**b**) Do the charges on ions A and C have the same or different signs? (**c**) Is the magnitude of the charge on ion B greater than, equal to, or less than the magnitude of the charge on ion C? [Section 5.1]



5.3 (**a**) Does the accompanying energy diagram represent an increase or decrease in the internal energy of the system? (**b**) What sign is given for this process? (**c**) If there is no work associated with the process, is it exothermic or endothermic? [Section 5.2]

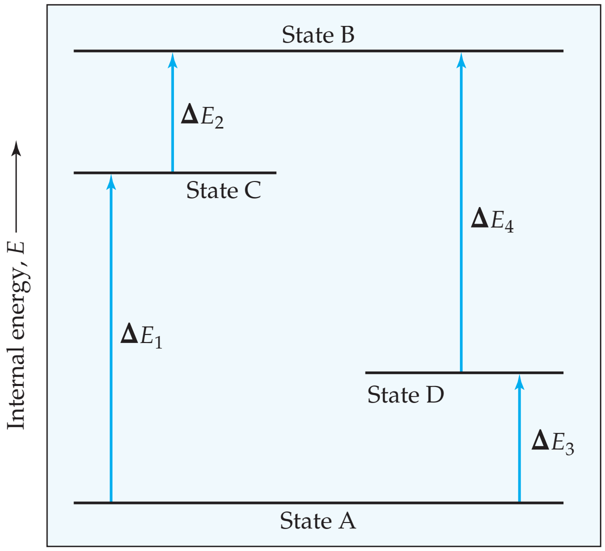


5.4 The contents of the closed box in each of the following illustrations represent a system, and the arrows show the changes to the system during some process. The lengths of the arrows represent the relative magnitudes of q and w. (**a**) Which of these processes is endothermic? (**b**) For which of these processes, if any, is $\Delta E < 0$? (**c**) For which process, if any, does the system experience a net gain in internal energy? [Section 5.2]



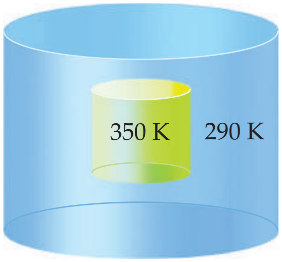
(i) (ii) (iii)

5.5 The diagram shows four states of a system, each with different internal energy, E. (**a**) Which of the states of the system has the greatest internal energy? (**b**) In terms of the ΔE values, write two expressions for the difference in internal energy between State A and State B. (**c**) Write an expression for the difference in energy between State C and State D. (**d**) Suppose there is another state of the system, State E, and its energy relative to State A is $\Delta E = \Delta E_1 + \Delta E_4$. Where would State E be on the diagram? [Section 5.2]

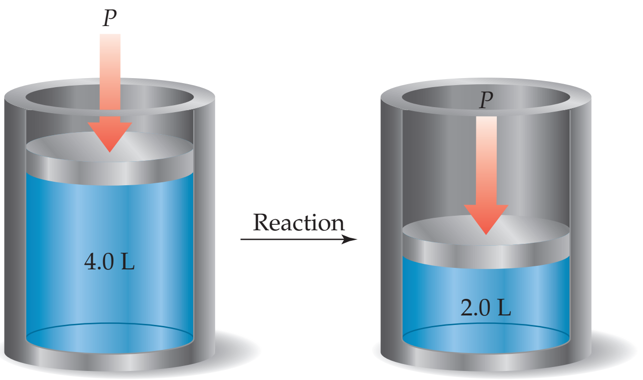


5.6 When you compress the air in a bicycle pump, the body of the pump gets warmer. (**a**) Assuming the pump and the air in it compose the system, what is the sign of w when you compress the air? (**b**) What is the sign of q for this process? (**c**) Based on your answers to parts (**a**) and (**b**), can you determine the sign of ΔE for compressing the air in the pump? If not, what would you expect for the sign of ΔE? What is your reasoning? [Section 5.2]

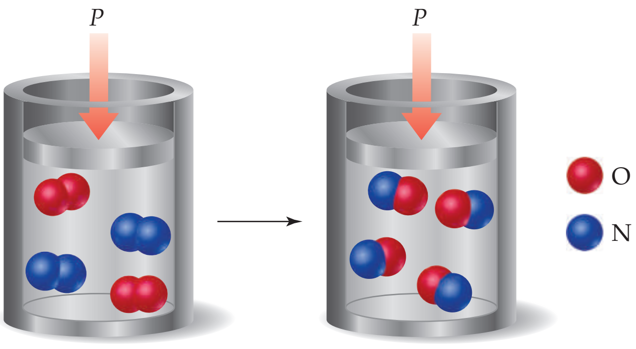
5.7 Imagine a container placed in a tub of water, as depicted in the accompanying diagram. (**a**) If the contents of the container are the system and heat is able to flow through the container walls, what qualitative changes will occur in the temperatures of the system and in its surroundings? From the system's perspective, is the process exothermic or endothermic? (**b**) If neither the volume nor the pressure of the system changes during the process, how is the change in internal energy related to the change in enthalpy? [Sections 5.2 and 5.3]



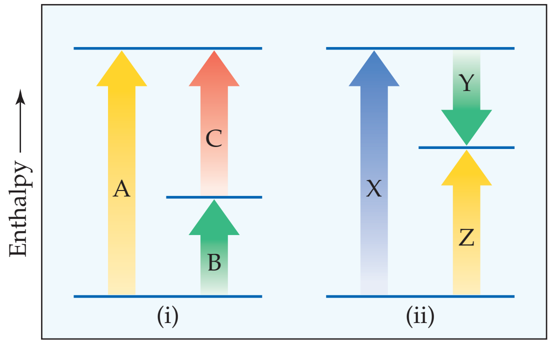
5.8 In the accompanying cylinder diagram, a chemical process occurs at constant temperature and pressure. (**a**) Is the sign of w indicated by this change positive or negative? (**b**) If the process is endothermic, does the internal energy of the system within the cylinder increase or decrease during the change, and is ΔE positive or negative? [Sections 5.2 and 5.3]



5.9 The gas-phase reaction shown, between N_2 and O_2, was run in an apparatus designed to maintain a constant pressure. (**a**) Write a balanced chemical equation for the reaction depicted and predict whether w is positive, negative, or zero. (**b**) Using data from Appendix C, determine ΔH for the formation of one mole of the product. [Sections 5.3 and 5.7]



5.10 Consider the two diagrams that follow. (**a**) Based on (i), write an equation showing how ΔH_A is related to ΔH_B and ΔH_C. (**b**) Based on (ii), write an equation relating ΔH_Z to the other enthalpy changes in the diagram. (**c**) The equations you obtained in parts (**a**) and (**b**) are based on what law? (**d**) Would similar relationships hold for the work involved in each process? [Section 5.6]



5.11 Consider the conversion of compound A into compound B: A $\longrightarrow$ B. For both compounds A and B, $\Delta H_f^\circ > 0$. (**a**) Sketch an enthalpy diagram for the reaction that is analogous to Figure 5.23. (**b**) Suppose the overall reaction is exothermic. What can you conclude? [Section 5.7]

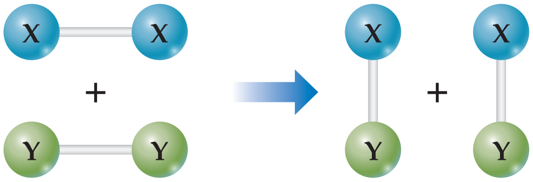
5.12 Consider the reaction pictured below in which a molecule of X_2 reacts with a molecule of Y_2 to form two molecules of XY. The reaction is exothermic. Which of the following statements involving the bond enthalpies of X_2, Y_2, and XY is or are *true*?

(**i**) $D(X–X)$, $D(Y—Y)$, and $D(X—Y)$ all have positive values.

(**ii**) $2D(X—Y) < D(X—X) + D(Y—Y)$.

(**iii**) $\Delta H = D(X—X) + D(Y—Y) - 2D(X—Y)$.

[Section 5.8]



The Nature of Chemical Energy (Section 5.1)

5.13 (**a**) What is the electrostatic potential energy (in joules) between an electron and a proton that are separated by 53 pm? (**b**) What is the change in potential energy if the distance separating the electron and proton is increased to 1.0 nm? (**c**) Does the potential energy of the two particles increase or decrease when the distance is increased to 1.0 nm?

5.14 (**a**) What is the electrostatic potential energy (in joules) between two protons that are separated by 62 pm? (**b**) What is the change in potential energy if the distance separating the two is increased to 1.0 nm? (**c**) Does the potential energy of the two particles increase or decrease when the distance is increased to 1.0 nm?

5.15 (**a**) The electrostatic force (not energy) of attraction between two oppositely charged objects is given by the equation $F = \kappa(Q_1Q_2/d^2)$ where $\kappa = 8.99 \times 10^9\ \text{N-m}^2/\text{C}^2$, Q_1 and Q_2 are the charges of the two objects in coulombs, and d is the distance separating the two objects in meters. What is the electrostatic force of attraction (in newtons) between an electron and a proton that are separated by 1.00×10^2 pm? (**b**) The force of gravity acting between two objects is given by the equation $F = G(m_1m_2/d^2)$, where $G = 6.674 \times 10^{-11}\ \text{N-m}^2/\text{kg}^2$ is the gravitational constant, m_1 and m_2 are the masses of the two objects, and d is the distance separating them. What is the gravitational force of attraction (in newtons) between the electron and proton? (**c**) How many times larger is the electrostatic force of attraction?

5.16 Use the equations given in Problem 5.15 to calculate: (**a**) The electrostatic force of repulsion for two protons separated by 75 pm. (**b**) The gravitational force of attraction for two protons separated by 75 pm. (**c**) If allowed to move, will the protons be repelled or attracted to one another?

5.17 A sodium ion, Na^+, with a charge of 1.6×10^{-19} C and a chloride ion, Cl^-, with a charge of -1.6×10^{-19} C, are separated by a distance of 0.50 nm. How much work would be required to increase the separation of the two ions to an infinite distance?

5.18 A magnesium ion, Mg^{2+}, with a charge of 3.2×10^{-19} C and an oxide ion, O^{2-}, with a charge of -3.2×10^{-19} C, are separated by a distance of 0.35 nm. How much work would be required to increase the separation of the two ions to an infinite distance?

The First Law of Thermodynamics (Section 5.2)

5.19 (**a**) Which of the following cannot leave or enter a closed system: heat, work, or matter? (**b**) Which cannot leave or enter an isolated system? (**c**) What do we call the part of the universe that is not part of the system?

5.20 Classify each of the following as an open, closed, or isolated system: (**a**) The air in a balloon. (**b**) The water in a puddle that is evaporating outdoors. (**c**) A cold beverage in an insulated jug. (**d**) A chemical reaction in a stoppered flask that produces heat.

5.21 (**a**) According to the first law of thermodynamics, what quantity is conserved? (**b**) What is meant by the *internal energy* of a system? (**c**) By what means can the internal energy of a closed system increase?

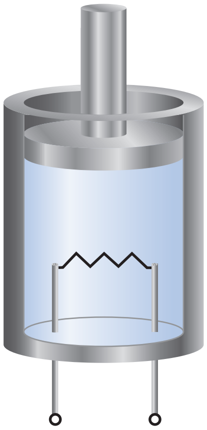
5.22 (**a**) Write an equation that expresses the first law of thermodynamics in terms of heat and work. (**b**) Under what conditions will the quantities q and w be negative numbers?

5.23 Calculate ΔE and determine whether the process is endothermic or exothermic for the following cases: (**a**) $q = 0.763$ kJ and $w = -840$ J. (**b**) A system releases 66.1 kJ of heat to its surroundings while the surroundings do 44.0 kJ of work on the system.

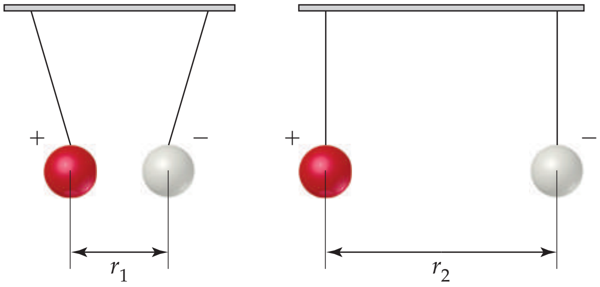
5.24 For the following processes, calculate the change in internal energy of the system and determine whether the process is endothermic or exothermic: (**a**) A balloon is cooled by removing 0.655 kJ of heat. It shrinks on cooling, and the atmosphere does 382 J of work on the balloon. (**b**) A 100.0-g bar of gold is heated from 25°C to 50°C during which it absorbs 322 J of heat. Assume the volume of the gold bar remains constant.

5.25 A gas is confined to a cylinder fitted with a piston and an electrical heater, as shown here:

Suppose that current is supplied to the heater so that 100 J of energy is added. Consider two different situations. In case (1) the piston is allowed to move as the energy is added. In case (2) the piston is fixed so that it cannot move. (**a**) In which case does the gas have the higher temperature after addition of the electrical energy? (**b**) Identify the sign (positive, negative, or zero) of q and w in each case? (**c**) In which case is ΔE for the system (the gas in the cylinder) larger?



5.26 Consider a system consisting of two oppositely charged spheres hanging by strings and separated by a distance r_1, as shown in the accompanying illustration. Suppose they are separated to a larger distance r_2, by moving them apart. (**a**) What change, if any, has occurred in the potential energy of the system? (**b**) What effect, if any, does this process have on the value of ΔE? (**c**) What can you say about q and w for this process?



5.27 Imagine that you are climbing a mountain. Which of the following are state functions? (**a**) The distance you walk during your climb to the top (**b**) The change in elevation during the climb (**c**) The change in your gravitational potential energy during the climb (**d**) The number of calories you expend during the climb.

5.28 Indicate which of the following is independent of the path by which a change occurs. (**a**) the change in potential energy when a book is transferred from table to shelf (**b**) the heat evolved when a cube of sugar is oxidized to $CO_2(g)$ and $H_2O(g)$ (**c**) the work accomplished in burning a gallon of gasoline.

5.29 A system goes from one state to another by two different paths. For Path 1, the system does 140 J of work on the surroundings, and its internal energy increases by 330 J. For Path 2, the system absorbs 220 J of heat from the surroundings. (**a**) What is the value of q for Path 1? (**b**) What is the value of w for Path 2?

5.30 A system goes from State A to State B by two different paths: Path 1, for which $q_1 = 38$ kJ and $w_1 = -97$ kJ,and Path 2, for which $q_2 = -28$ kJ. (**a**) What is the value of ΔE for Path 1? (**b**) What is the value of w for Path 2?

Enthalpy (Sections 5.3 and 5.4)

5.31 During a normal breath, our lungs expand about 0.50 L against an external pressure of 1.0 atm. How much work is involved in this process (in J)?

5.32 How much work (in J) is involved in a chemical reaction if the volume decreases from 5.00 to 1.26 L against a constant pressure of 0.857 atm?

5.33 Which of the following statements about enthalpy is or are *true*?

(**i**) Because E, P, and V are state functions, H is a state function.

(**ii**) If a system changes its state under a constant external pressure, then $\Delta H = q$.

(**iii**) Under constant-pressure conditions, if $\Delta H = 0$, then ΔE must also equal zero.

5.34 (**a**) Under what condition will the enthalpy change of a process equal the amount of heat transferred into or out of the system? (**b**) During a constant-pressure process, the system releases heat to the surroundings. Does the enthalpy of the system increase or decrease during the process? (**c**) In a constant-pressure process, $\Delta H = 0$. What can you conclude about ΔE, q, and w?

5.35 Assume that the following reaction occurs at constant pressure:

$$2\,Al(s) + 3\,Cl_2(g) \longrightarrow 2\,AlCl_3(s)$$

(**a**) If you are given ΔH for the reaction, what additional information do you need to determine ΔE for the process? (**b**) Which quantity is larger for this reaction? (**c**) Explain your answer to part (**b**).

5.36 Suppose that the gas-phase reaction $2\,NO(g) + O_2(g) \longrightarrow 2\,NO_2(g)$ were carried out in a constant-volume container at constant temperature. (**a**) Would the measured heat change represent ΔH or ΔE? (**b**) If there is a difference, which quantity is larger for this reaction? (**c**) Explain your answer to part (**b**).

5.37 A gas is confined to a cylinder under constant atmospheric pressure, as illustrated in Figure 5.4. When the gas undergoes a particular chemical reaction, it absorbs 824 J of heat from its surroundings and has 0.65 kJ of P–V work done on it by its surroundings. What are the values of ΔH and ΔE for this process?

5.38 A gas is confined to a cylinder under constant atmospheric pressure, as illustrated in Figure 5.4. When 0.49 kJ of heat is added to the gas, it expands and does 214 J of work on the surroundings. What are the values of ΔH and ΔE for this process?

5.39 The complete combustion of ethanol, $C_2H_5OH(l)$, to form $H_2O(g)$ and $CO_2(g)$ at constant pressure releases 1235 kJ of heat per mole of C_2H_5OH. (**a**) Write a balanced thermochemical equation for this reaction. (**b**) Draw an enthalpy diagram for the reaction.

5.40 The decomposition of $Ca(OH)_2(s)$ into $CaO(s)$ and $H_2O(g)$ at constant pressure requires the addition of 109 kJ of heat per mole of $Ca(OH)_2$. (**a**) Write a balanced thermochemical equation for the reaction. (**b**) Draw an enthalpy diagram for the reaction.

5.41 Ozone, $O_3(g)$, is a form of elemental oxygen that plays an important role in the absorption of ultraviolet radiation in the stratosphere. It decomposes to $O_2(g)$ at room temperature and pressure according to the following reaction:

$$2\,O_3(g) \longrightarrow 3\,O_2(g) \quad \Delta H = -284.6\text{ kJ}$$

(**a**) What is the enthalpy change for this reaction per mole of $O_3(g)$? (**b**) Which has the higher enthalpy under these conditions, $2\,O_3(g)$ or $3\,O_2(g)$?

5.42 Without referring to tables, predict which of the following has the higher enthalpy in each case: (**a**) 1 mol $CO_2(s)$ or 1 mol $CO_2(g)$ at the same temperature (**b**) 2 mol of hydrogen atoms or 1 mol of H_2 (**c**) 1 mol $H_2(g)$ and 0.5 mol $O_2(g)$ at 25 °C or 1 mol $H_2O(g)$ at 25 °C (**d**) 1 mol $N_2(g)$ at 100 °C or 1 mol $N_2(g)$ at 300 °C

5.43 Consider the following reaction:

$$2\,Mg(s) + O_2(g) \longrightarrow 2\,MgO(s) \quad \Delta H = -1204\text{ kJ}$$

(**a**) Is this reaction exothermic or endothermic? (**b**) Calculate the amount of heat transferred when 3.55 g of $Mg(s)$ reacts at constant pressure. (**c**) How many grams of MgO are produced during an enthalpy change of −234 kJ? (**d**) How many kilojoules of heat are absorbed when 40.3 g of $MgO(s)$ is decomposed into $Mg(s)$ and $O_2(g)$ at constant pressure?

5.44 Consider the following reaction:

$$2\,CH_3OH(g) \longrightarrow 2\,CH_4(g) + O_2(g) \quad \Delta H = +252.8\text{ kJ}$$

(**a**) Is this reaction exothermic or endothermic? (**b**) Calculate the amount of heat transferred when 24.0 g of $CH_3OH(g)$ is decomposed by this reaction at constant pressure. (**c**) For a given sample of CH_3OH, the enthalpy change during the reaction is 82.1 kJ. How many grams of methane gas are produced? (**d**) How many kilojoules of heat are released when 38.5 g of $CH_4(g)$ react completely with $O_2(g)$ to form $CH_3OH(g)$ at constant pressure?

5.45 When solutions containing silver ions and chloride ions are mixed, silver chloride precipitates:

$$Ag^+(aq) + Cl^-(aq) \longrightarrow AgCl(s) \quad \Delta H = -65.5\text{ kJ}$$

(**a**) Calculate ΔH for the production of 0.450 mol of AgCl by this reaction. (**b**) Calculate ΔH for the production of 9.00 g of AgCl. (**c**) Calculate ΔH when 9.25×10^{-4} mol of AgCl dissolves in water.

5.46 At one time, a common means of forming small quantities of oxygen gas in the laboratory was to heat $KClO_3$:

$$2\,KClO_3(s) \longrightarrow 2\,KCl(s) + 3\,O_2(g) \quad \Delta H = -89.4\text{ kJ}$$

For this reaction, calculate ΔH for the formation of (**a**) 1.36 mol of O_2 and (**b**) 10.4 g of KCl. (**c**) Now consider the reverse reaction, in which $KClO_3$ is formed from KCl and O_2. What is ΔH for the formation of 19.1 g $KClO_3$ from KCl and O_2. (**d**) Would you expect the reaction in part (c) to occur spontaneously?

5.47 Consider the combustion of *isopropanol*, $C_3H_7OH(l)$, which is the primary component of rubbing alcohol:

$$C_3H_7OH(l) + 9/2\,O_2(g) \rightarrow 3\,CO_2(g) + 4\,H_2O(l) \quad \Delta H = -2248\text{ kJ}$$

(**a**) What is the enthalpy change for the reverse reaction? (**b**) Balance the forward reaction with whole-number coefficients. What is ΔH for the reaction represented by this equation? (**c**) Which is more likely to be thermodynamically favored, the forward reaction or the reverse reaction? (**d**) If the reaction were written to produce $H_2O(g)$ instead of $H_2O(l)$, would you expect the magnitude of ΔH to increase, decrease, or stay the same?

5.48 Consider the decomposition of liquid benzene, $C_6H_6(l)$, to gaseous acetylene, $C_2H_2(g)$:

$$C_6H_6(l) \longrightarrow 3\,C_2H_2(g) \quad \Delta H = +630\text{ kJ}$$

(**a**) What is the enthalpy change for the reverse reaction? (**b**) What is ΔH for the formation of 1 mol of acetylene? (**c**) Which is more likely to be thermodynamically favored, the forward reaction or the reverse reaction? (**d**) If $C_6H_6(g)$ were consumed instead of $C_6H_6(l)$, would you expect the magnitude of ΔH to increase, decrease, or stay the same?

Calorimetry (Section 5.5)

5.49 (**a**) What are the units of molar heat capacity? (**b**) What are the units of specific heat? (**c**) If you know the specific heat of copper, what additional information do you need to calculate the heat capacity of a particular piece of copper pipe?

5.50 Two solid objects, A and B, are placed in boiling water and allowed to come to the temperature of the water. Each is then lifted out and placed in separate beakers containing 1000 g water at 10.0°C. Object A increases the water temperature by 3.50°C; B increases the water temperature by 2.60 °C. (**a**) Which object has the larger heat capacity? (**b**) What can you say about the specific heats of A and B?

5.51 (**a**) What is the specific heat of liquid water? (**b**) What is the molar heat capacity of liquid water? (**c**) What is the heat capacity of 185 g of liquid water? (**d**) How many kJ of heat are needed to raise the temperature of 10.00 kg of liquid water from 24.6 to 46.2°C?

5.52 (**a**) Which substance in Table 5.2 requires the smallest amount of energy to increase the temperature of 50.0 g of that substance by 10 K? (**b**) Calculate the energy needed for this temperature change.

5.53 The specific heat of ethanol, $C_2H_5OH(l)$, is 2.44 J/g-K. (**a**) How many J of heat are needed to raise the temperature of 80.0 g of ethanol from 10.0 to 25.0°C? (**b**) Which will require more heat, increasing the temperature of 1 mol of $C_2H_5OH(l)$ by a certain amount or increasing the temperature of 1 mol of $H_2O(l)$ by the same amount?

5.54 Consider the data about gold metal in Exercise 5.24(b). (**a**) Based on the data, calculate the specific heat of $Au(s)$. (**b**) Suppose that the same amount of heat is added to two 10.0-g blocks of metal, both initially at the same temperature. One block is gold metal, and the other is iron metal. Which block will have the greater rise in temperature after addition of the heat? (**c**) What is the molar heat capacity of $Au(s)$?

5.55 When a 5.10-g sample of solid sodium hydroxide dissolves in 100.0 g of water in a coffee-cup calorimeter (Figure 5.18), the temperature rises from 20.5 to 33.2 °C. (**a**) Calculate the quantity of heat (in kJ) released in the reaction. (**b**) Using your result from part (**a**), calculate ΔH (in kJ/mol NaOH) for the solution process. Assume that the specific heat of the solution is the same as that of pure water.

5.56 (**a**) When a 6.50-g sample of solid ammonium nitrate dissolves in 60.0 g of water in a coffee-cup calorimeter (Figure 5.18), the temperature drops from 21.8 to 14.0 °C. Calculate ΔH (in kJ/mol NH_4NO_3)) for the solution process:

$$NH_4NO_3(s) \longrightarrow NH_4^+(aq) + NO_3^-(aq)$$

Assume that the specific heat of the solution is the same as that of pure water. (**b**) Is this process endothermic or exothermic?

5.57 A 2.200-g sample of quinone ($C_6H_4O_2$) is burned in a bomb calorimeter whose total heat capacity is 7.854 kJ/°C. The temperature of the calorimeter increases from 23.44 to 30.57 °C. (**a**) What is the heat of combustion per gram of quinone? (**b**) What is the heat of combustion per mole of quinone?

5.58 A 1.800-g sample of phenol (C_6H_5OH) was burned in a bomb calorimeter whose total heat capacity is 11.66 kJ/°C. The temperature of the calorimeter plus contents increased from 21.36 to 26.37°C. (**a**) Write a balanced chemical equation for the bomb calorimeter reaction. (**b**) What is the heat of combustion per gram of phenol? (**c**) What is the heat of combustion per mole of phenol?

5.59 Under constant-volume conditions, the heat of combustion of benzoic acid (C_6H_5COOH) is 26.38 kJ/g. A 2.760-g sample of benzoic acid is burned in a bomb calorimeter. The temperature of the calorimeter increases from 21.60 to 29.93°C. (**a**) What is the total heat capacity of the calorimeter? (**b**) A 1.440-g sample of a new organic substance is combusted in the same calorimeter. The temperature of the calorimeter increases from 22.14 to 27.09°C. What is the heat of combustion per gram of the new substance? (**c**) Suppose that in changing samples, a portion of the water in the calorimeter was lost. In what way, if any, would this change the heat capacity of the calorimeter?

5.60 *Glycerol* (also called *glycerine*), $C_3H_8O_3(l)$, is a viscous, sweet-tasting liquid used in a variety of food and personal care products. Under constant-volume conditions, the combustion of 1.000 mol of glycerol releases 1653 kJ of heat to the surroundings. A 2.850-g sample of glycerol is burned in a bomb calorimeter. The temperature of the calorimeter increases from 22.11 to 27.42 °C. (**a**) Write a balanced equation for the combustion reaction, assuming the products are $CO_2(g)$ and $H_2O(l)$. (**b**) What is the total heat capacity of the calorimeter? (**c**) If the size of the glucose sample had been 4.000 g, what would the temperature change of the calorimeter have been? (**d**) Which of the following values about the combustion of glycerol under constant volume is or are correct: (i) $\Delta H = -1653$ kJ/mol; (ii) $\Delta E = -1653$ kJ/mol; (iii) $q_V = -1653$ kJ/mol?

Hess's Law (Section 5.6)

5.61 Consider the following hypothetical reactions:

$$\begin{aligned} A &\longrightarrow B \quad \Delta H = +30\ \text{kJ} \\ B &\longrightarrow C \quad \Delta H = +60\ \text{kJ} \end{aligned}$$

(**a**) Use Hess's law to calculate the enthalpy change for the reaction $A \longrightarrow C$. (**b**) Construct an enthalpy diagram for substances A, B, and C, and show how Hess's law applies.

5.62 You are given the following hypothetical reactions:

$$\begin{aligned} 2\,A &\longrightarrow B + C \quad &\Delta H = +50\ \text{kJ} \\ A &\longrightarrow D &\Delta H = -80\ \text{kJ} \end{aligned}$$

Use Hess's law to calculate ΔH for the reaction $B + C \longrightarrow 2\,D$. (**b**) What is ΔH for the reaction $D \longrightarrow \tfrac{1}{2}\,B + \tfrac{1}{2}\,C$?

5.63 Calculate the enthalpy change for the reaction

$$P_4O_6(s) + 2\,O_2(g) \longrightarrow P_4O_{10}(s)$$

given the following enthalpies of reaction:

$$\begin{aligned} P_4(s) + 3\,O_2(g) &\longrightarrow P_4O_6(s) \quad &\Delta H = -1640.1\ \text{kJ} \\ P_4(s) + 5\,O_2(g) &\longrightarrow P_4O_{10}(s) &\Delta H = -2940.1\ \text{kJ} \end{aligned}$$

5.64 From the enthalpies of reaction

$$\begin{aligned} 2\,C(s) + O_2(g) &\longrightarrow 2\,CO(g) \quad &\Delta H = -221.0\ \text{kJ} \\ 2\,C(s) + O_2(g) + 4\,H_2(g) &\longrightarrow 2\,CH_3OH(g) &\Delta H = -402.4\ \text{kJ} \end{aligned}$$

calculate ΔH for the reaction

$$CO(g) + 2\,H_2(g) \longrightarrow CH_3OH(g)$$

5.65 From the enthalpies of reaction

$$\begin{aligned} H_2(g) + F_2(g) &\longrightarrow 2\,HF(g) \quad &\Delta H = -537\ \text{kJ} \\ C(s) + 2\,F_2(g) &\longrightarrow CF_4(g) &\Delta H = -680\ \text{kJ} \\ 2\,C(s) + 2\,H_2(g) &\longrightarrow C_2H_4(g) &\Delta H = +52.3\ \text{kJ} \end{aligned}$$

calculate ΔH for the reaction of ethylene with F_2:

$$C_2H_4(g) + 6\,F_2(g) \longrightarrow 2\,CF_4(g) + 4\,HF(g)$$

5.66 Given the data

$$\begin{aligned} N_2(g) + O_2(g) &\longrightarrow 2\,NO(g) \quad &\Delta H = +180.7\ \text{kJ} \\ 2\,NO(g) + O_2(g) &\longrightarrow 2\,NO_2(g) &\Delta H = -113.1\ \text{kJ} \\ 2\,N_2O(g) &\longrightarrow 2\,N_2(g) + O_2(g) &\Delta H = -163.2\ \text{kJ} \end{aligned}$$

use Hess's law to calculate ΔH for the reaction

$$N_2O(g) + NO_2(g) \longrightarrow 3\,NO(g)$$

5.67 We can use Hess's law to calculate enthalpy changes that cannot be measured. One such reaction is the conversion of methane to ethylene:

$$2\,CH_4(g) \longrightarrow C_2H_4(g) + 2\,H_2(g)$$

Calculate $\Delta H°$ for this reaction using the following thermochemical data:

$$\begin{aligned} CH_4(g) + 2\,O_2(g) &\longrightarrow CO_2(g) + 2\,H_2O(l) \quad &\Delta H° = -890.3\ \text{kJ} \\ C_2H_4(g) + H_2(g) &\longrightarrow C_2H_6(g) &\Delta H° = -136.3\ \text{kJ} \\ 2\,H_2(g) + O_2(g) &\longrightarrow 2\,H_2O(l) &\Delta H° = -571.6\ \text{kJ} \\ 2\,C_2H_6(g) + 7\,O_2(g) &\longrightarrow 4\,CO_2(g) + 6\,H_2O(l) &\Delta H° = -3120.8\ \text{kJ} \end{aligned}$$

5.68 Dimethyl ether, $CH_3OCH_3(g)$, is an industrially useful organic compound that is a gas at room temperature. Consider the following balanced thermochemical equations:

$$\begin{aligned} CH_3OCH_3(g) + 3\,O_2(g) &\longrightarrow 2\,CO_2(g) + 3\,H_2O(g) \quad &\Delta H° = -1328\ \text{kJ} \\ CH_4(g) + 2\,O_2(g) &\longrightarrow CO_2(g) + 2\,H_2O(g) &\Delta H° = -802\ \text{kJ} \\ 2\,C_2H_6(g) + 7\,O_2(g) &\longrightarrow 4\,CO_2(g) + 6\,H_2O(g) &\Delta H° = -2855\ \text{kJ} \end{aligned}$$

(**a**) All three of the above reactions produce $H_2O(g)$. If they were written to produce $H_2O(l)$ instead, would the values of $\Delta H°$ become more negative, become less negative, or stay the same? (**b**) By using Hess's law and the reactions provided, calculate $\Delta H°$ for the following balanced reaction between dimethyl ether and methane to produce ethane and water:

$$CH_3OCH_3(g) + 2\,CH_4(g) \longrightarrow 2\,C_2H_6(g) + H_2O(g)$$

Enthalpies of Formation (Section 5.7)

5.69 (**a**) What is meant by the term *standard conditions* with reference to enthalpy changes? (**b**) What is meant by the term *enthalpy of formation*? (**c**) What is meant by the term *standard enthalpy of formation*?

5.70 (**a**) What is the value of the standard enthalpy of formation of an element in its most stable form? (**b**) Write the chemical equation for the reaction whose enthalpy change is the standard enthalpy of formation of sucrose (table sugar), $C_{12}H_{22}O_{11}(s)$, $\Delta H_f^\circ[C_{12}H_{22}O_{11}(s)]$.

5.71 For each of the following compounds, write a balanced thermochemical equation depicting the formation of one mole of the compound from its elements in their standard states and then look up ΔH_f° for each substance in Appendix C. **(a)** $N_2O(g)$ **(b)** $FeCl_3(s)$ **(c)** $P_4O_{10}(s)$ **(d)** $Ca(OH)_2(s)$

5.72 Write balanced equations that describe the formation of the following compounds from elements in their standard states, and then look up the standard enthalpy of formation for each substance in Appendix C. **(a)** $NH_4NO_3(s)$ **(b)** $K_2CO_3(s)$ **(c)** $SOCl_2(l)$ **(d)** $NaHCO_3(s)$

5.73 The following is known as the thermite reaction:

$$2\,Al(s) + Fe_2O_3(s) \longrightarrow Al_2O_3(s) + 2\,Fe(s)$$

This highly exothermic reaction is used for welding massive units, such as propellers for large ships. Using standard enthalpies of formation in Appendix C, calculate ΔH° for this reaction.

5.74 Many portable gas heaters and grills use propane, $C_3H_8(g)$, as a fuel. Using standard enthalpies of formation, calculate the quantity of heat produced when 10.0 g of propane is completely combusted in air under standard conditions.

5.75 Using values from Appendix C, calculate the standard enthalpy change for each of the following reactions:

(a) $2\,PCl_3(g) + O_2(g) \longrightarrow 2\,POCl_3(g)$

(b) $PbCO_3(s) \longrightarrow PbO(s) + CO_2(g)$

(c) $2\,FeCl_3(s) + 3\,H_2(g) \longrightarrow 2\,Fe(s) + 6\,HCl(g)$

(d) $2\,H_2O_2(l) \longrightarrow 2\,H_2O(l) + O_2(g)$

5.76 Using values from Appendix C, calculate the value of ΔH° for each of the following reactions:

(a) $NiO(s) + 2\,HCl(g) \longrightarrow NiCl_2(s) + H_2O(g)$

(b) $2\,NO_2(g) \longrightarrow N_2O_4(g)$

(c) $2\,HBr(g) + F_2(g) \longrightarrow 2\,HF(g) + Br_2(g)$

(d) $TiCl_4(l) + 2\,H_2O(l) \longrightarrow TiO_2(s) + 4\,HCl(aq)$

5.77 Complete combustion of 1 mol of acetone (C_3H_6O) liberates 1790 kJ:

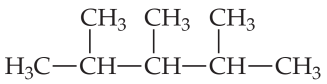
$$C_3H_6O(l) + 4\,O_2(g) \longrightarrow 3\,CO_2(g) + 3\,H_2O(l) \qquad \Delta H^\circ = -1790\ \text{kJ}$$

Using this information together with the standard enthalpies of formation of $O_2(g)$, $CO_2(g)$, and $H_2O(l)$ from Appendix C, calculate the standard enthalpy of formation of acetone.

5.78 Calcium carbide (CaC_2) reacts with water to form acetylene (C_2H_2) and $Ca(OH)_2$. From the following enthalpy of reaction data and data in Appendix C, calculate ΔH_f° for $CaC_2(s)$:

$$CaC_2(s) + 2\,H_2O(l) \longrightarrow Ca(OH)_2(s) + C_2H_2(g) \qquad \Delta H^\circ = -127.2\ \text{kJ}$$

5.79 Gasoline is composed primarily of hydrocarbons, including many with eight carbon atoms, called *octanes*. One of the cleanest-burning octanes is a compound called 2,3,4-trimethylpentane, which has the following structural formula:



$$H_3C-\overset{\overset{CH_3}{|}}{CH}-\overset{\overset{CH_3}{|}}{CH}-\overset{\overset{CH_3}{|}}{CH}-CH_3$$

The complete combustion of one mole of this compound to $CO_2(g)$ and $H_2O(g)$ leads to $\Delta H^\circ = -5064.9$ kJ. **(a)** Write a balanced equation for the combustion of 1 mol of $C_8H_{18}(l)$. **(b)** By using the information in this problem and data in Table 5.3, calculate ΔH_f° for 2,3,4-trimethylpentane.

5.80 Diethyl ether, $C_4H_{10}O(l)$, a flammable compound that was once used as a surgical anesthetic, has the structure:

$$H_3C-CH_2-O-CH_2-CH_3$$

The complete combustion of 1 mol of $C_4H_{10}O(l)$ to $CO_2(g)$ and $H_2O(l)$ yields $\Delta H^\circ = -2723.7$ kJ. **(a)** Write a balanced equation for the combustion of 1 mol of $C_4H_{10}O(l)$. **(b)** By using the information in this problem and the data in Table 5.3, calculate ΔH_f° for diethyl ether.

5.81 Ethanol (C_2H_5OH) is blended with gasoline as an automobile fuel. **(a)** Write a balanced equation for the combustion of liquid ethanol in air. **(b)** Calculate the standard enthalpy change for the reaction, assuming $H_2O(g)$ as a product. **(c)** Calculate the heat produced per liter of ethanol by combustion of ethanol under constant pressure. Ethanol has a density of 0.789 g/mL. **(d)** Calculate the mass of CO_2 produced per kJ of heat emitted.

5.82 Methanol (CH_3OH) is used as a fuel in race cars. **(a)** Write a balanced equation for the combustion of liquid methanol in air. **(b)** Calculate the standard enthalpy change for the reaction, assuming $H_2O(g)$ as a product. **(c)** Calculate the heat produced by combustion per liter of methanol. Methanol has a density of 0.791 g/mL. **(d)** Calculate the mass of CO_2 produced per kJ of heat emitted.

Bond Enthalpies (Section 5.8)

5.83 Which of the following statements about average bond enthalpies is or are *true*?

(i) It always requires energy to break a bond.

(ii) It requires more energy to break a single bond than to break a double bond.

(iii) Bond enthalpies can be used to estimate the reaction enthalpies of gas-phase reactions.

5.84 Which of the following statements about average bond enthalpies is or are *true*?

(i) Bond enthalpies are always positive values.

(ii) When a bond is made, energy is released that is equal in magnitude to the bond enthalpy.

(iii) The bond enthalpy of any element in its most stable state is zero.

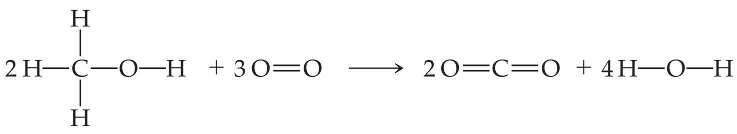
5.85 **(a)** Use enthalpies of formation given in Appendix C to calculate ΔH for the reaction $CCl_4(g) \rightarrow C(g) + 4\,Cl(g)$, and use this value to estimate the bond enthalpy $D(C{-}Cl)$. **(b)** How large is the difference between the value calculated in part **(a)** and the value given in Table 5.4?

5.86 Ethane, C_2H_6, is an alkane with one C—C bond and six C—H bonds (Section 2.9). **(a)** Use enthalpies of formation given in Appendix C to calculate ΔH for the reaction $C_2H_6(g) \rightarrow 2\,C(g) + 6\,H(g)$. **(b)** Use the result from part (a) and the value of $D(C{-}H)$ from Table 5.4 to estimate the bond enthalpy $D(C{-}C)$. **(c)** How large is the difference between the value calculated for $D(C{-}C)$ in part (b) and the value given in Table 5.4?

5.87 Use bond enthalpies in Table 5.4 to estimate ΔH for each of the following reactions:

(a) $H{-}H(g) + Br{-}Br(g) \longrightarrow 2\,H{-}Br(g)$

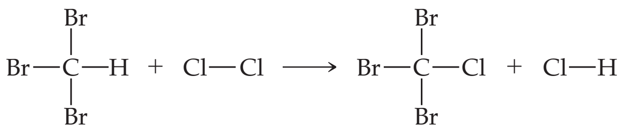
(**b**)



$$2\,\mathrm{H{-}\underset{\displaystyle H}{\overset{\displaystyle H}{C}}{-}O{-}H} + 3\,\mathrm{O{=}O} \longrightarrow 2\,\mathrm{O{=}C{=}O} + 4\,\mathrm{H{-}O{-}H}$$

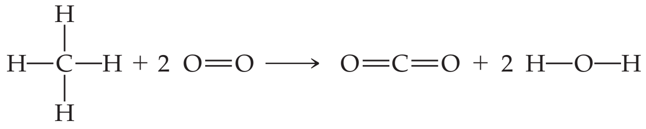
5.88 Use bond enthalpies in Table 5.4 to estimate ΔH for each of the following reactions:

(**a**)



$$\mathrm{Br{-}\underset{\displaystyle Br}{\overset{\displaystyle Br}{C}}{-}H} + \mathrm{Cl{-}Cl} \longrightarrow \mathrm{Br{-}\underset{\displaystyle Br}{\overset{\displaystyle Br}{C}}{-}Cl} + \mathrm{Cl{-}H}$$

(**b**)



$$\mathrm{H{-}\underset{\displaystyle H}{\overset{\displaystyle H}{C}}{-}H} + 2\ \mathrm{O{=}O} \longrightarrow \mathrm{O{=}C{=}O} + 2\ \mathrm{H{-}O{-}H}$$

5.89 Consider the reaction $2\,H_2(g) + O_2(g) \rightarrow 2\,H_2O(l)$. (**a**) Use the bond enthalpies in Table 5.4 to estimate ΔH for this reaction, ignoring the fact that water is in the liquid state. (**b**) Without doing a calculation, predict whether your estimate in part (**a**) is more negative or less negative than the true reaction enthalpy. (**c**) Use the enthalpies of formation in Appendix C to determine the true reaction enthalpy.

5.90 Consider the reaction $H_2(g) + I_2(s) \rightarrow 2HI(g)$. (**a**) Use the bond enthalpies in Table 5.4 to estimate ΔH for this reaction, ignoring the fact that iodine is in the solid state. (**b**) Without doing a calculation, predict whether your estimate in part (**a**) is more negative or less negative than the true reaction enthalpy. (**c**) Use the enthalpies of formation in Appendix C to determine the true reaction enthalpy.

Foods and Fuels (Section 5.9)

5.91 (**a**) What is meant by the term *fuel value*? (**b**) Which is a greater source of energy as food, 5 g of fat or 9 g of carbohydrate? (**c**) The metabolism of glucose produces $CO_2(g)$ and $H_2O(l)$. How does the human body expel these reaction products?

5.92 (**a**) Which releases the most energy when metabolized, 1 g of carbohydrates or 1 g of fat? (**b**) A particular chip snack food is composed of 12% protein, 14% fat, and the rest carbohydrate. What percentage of the calorie content of this food is fat? (**c**) How many grams of protein provide the same fuel value as 25 g of fat?

5.93 (**a**) A serving of a particular ready-to-serve chicken noodle soup contains 2.5 g fat, 14 g carbohydrate, and 7 g protein. Estimate the number of Calories in a serving. (**b**) According to its nutrition label, the same soup also contains 690 mg of sodium. Do you think the sodium contributes to the caloric content of the soup?

5.94 A pound of plain M&M® candies contains 96 g fat, 320 g carbohydrate, and 21 g protein. What is the fuel value in kJ in a 42-g (about 1.5 oz) serving? How many Calories does it provide?

5.95 The heat of combustion of fructose, $C_6H_{12}O_6$, is -2812 kJ/mol. If a fresh golden delicious apple weighing 4.23 oz (120 g) contains 16.0 g of fructose, what caloric content does the fructose contribute to the apple?

5.96 The heat of combustion of ethanol, $C_2H_5OH(l)$, is -1367 kJ/mol. A batch of Sauvignon Blanc wine contains 10.6% ethanol by mass. Assuming the density of the wine to be 1.0 g/mL, what is the caloric content due to the alcohol (ethanol) in a 6-oz glass of wine (177 mL)?

5.97 The standard enthalpies of formation of gaseous propyne (C_3H_4), propylene (C_3H_6), and propane (C_3H_8) are +185.4, +20.4, and −103.8 kJ/mol, respectively. (**a**) Calculate the heat evolved per mole on combustion of each substance to yield $CO_2(g)$ and $H_2O(g)$. (**b**) Calculate the heat evolved on combustion of 1 kg of each substance. (**c**) Which is the most efficient fuel in terms of heat evolved per unit mass?

5.98 Methane, $CH_4(g)$, is the principal component of natural gas. Natural gas vehicles (NGVs) have become increasingly popular, in part because methane is a cleaner fuel than gasoline with regard to the production of atmospheric CO_2 as well as other pollutants. The principal component of gasoline is octane, $C_8H_{18}(l)$. The thermochemical equations for the combustion of methane and octane are:

$$CH_4(g) + 2\,O_2(g) \longrightarrow CO_2(g) + 2\,H_2O(l) \quad \Delta H = -890.4\text{ kJ}$$

$$C_8H_{18}(l) + 25/2\,O_2(g) \longrightarrow 8\,CO_2(g) + 9\,H_2O(l) \quad \Delta H = -5471\text{ kJ}$$

(**a**) What are the fuel values of methane and octane, in kJ/g? (**b**) For combustion of methane, what is the heat released per mol CO_2 generated? (**c**) For combustion of octane, what is the heat released per mol CO_2 generated? (**d**) A typical metropolitan bus requires about 23,200 kJ of energy from combustion per mile traveled. If an octane-powered bus travels 50.0 mi during a day, what mass of CO_2 in kg is produced? (**e**) If the bus in part (d) were powered by methane instead of octane, what mass of CO_2 in kg is produced?

5.99 At the end of 2020, global population was about 7.8 billion. What mass of glucose in kg would be needed to provide 1500 Cal/person/day of nourishment to the global population for one year? Assume that glucose is metabolized entirely to $CO_2(g)$ and $H_2O(l)$ according to the following thermochemical equation:

$$C_6H_{12}O_6(s) + 6\,O_2(g) \longrightarrow 6\,CO_2(g) + 6\,H_2O(l) \qquad \Delta H^\circ = -2803\text{ kJ}$$

5.100 The automobile fuel called E85 consists of 85% ethanol and 15% gasoline. E85 can be used in the so-called flex-fuel vehicles (FFVs), which can use gasoline, ethanol, or a mix as fuel. Assume that gasoline consists of a mixture of octanes (different isomers of C_8H_{18}), that the average heat of combustion of $C_8H_{18}(l)$ is 5400 kJ/mol, and that gasoline has an average density of 0.70 g/mL. The density of ethanol is 0.79 g/mL. (**a**) By using the information given as well as data in Appendix C, compare the energy produced by combustion of 1.0 L of gasoline and of 1.0 L of ethanol. (**b**) Assume that the density and heat of combustion of E85 can be obtained by using 85% of the values for ethanol and 15% of the values for gasoline. How much energy could be released by the combustion of 1.0 L of E85? (**c**) How many gallons of E85 would be needed to provide the same energy as 10 gal of gasoline? (**d**) If gasoline costs $3.88 per gallon in the United States, what is the break-even price per gallon of E85 if the same amount of energy is to be delivered?

Additional Exercises

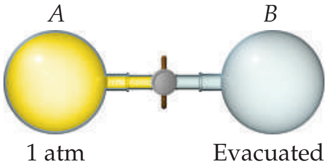
5.101 Two positively charged spheres, each with a charge of 2.0×10^{-5} C, a mass of 1.0 kg, and separated by a distance of 1.0 cm, are held in place on a frictionless track. (**a**) What is the electrostatic potential energy of this system? (**b**) If the spheres are released, will they move toward or away from each other? (**c**) What speed will each sphere attain as the distance between the spheres approaches infinity? [Section 5.1]

5.102 Identify whether work is being performed for each of the following. (**a**) a rock is thrown into the sky (**b**) two strong magnets are held at a fixed distance from one another (**c**) a bicyclist starts a ride by pushing on the pedals (**d**) a spring is compressed to half its original length (**e**) a gas expands into a vacuum

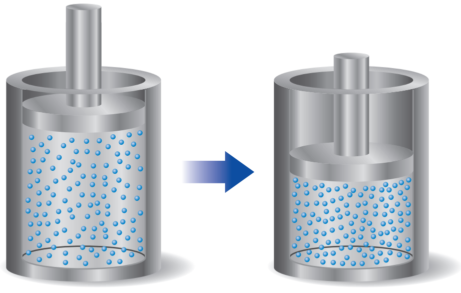
5.103 The air bags that provide protection in automobiles in the event of an accident expand because of a rapid chemical reaction. From the viewpoint of the chemical reactants as the system, what do you expect for the signs of q and w in this process?

5.104 An aluminum can of a soft drink is placed in a freezer. Later, you find that the can is split open and its contents have frozen. Work was done on the can in splitting it open. Where did the energy for this work come from?

5.105 Consider a system consisting of the following apparatus, in which gas is confined in one flask and there is a vacuum in the other flask. The flasks are separated by a valve. Assume that the flasks are perfectly insulated and will not allow the flow of heat into or out of the flasks to the surroundings. When the valve is opened, gas flows from the filled flask to the evacuated one. (**a**) Is work performed during the expansion of the gas? (**b**) Why or why not? (**c**) Can you determine the value of ΔE for the process?



5.106 A system consists of a sample of gas contained in a cylinder-and-piston arrangement. It undergoes the change in state shown in the drawing under two different situations: In Case 1, the cylinder and piston are perfect thermal insulators that do not allow heat to be transferred. In Case 2, the cylinder and piston are made up of a thermal conductor such as a metal, and during the state change, the cylinder gets warmer to the touch. Let q_1, w_1, and ΔE_1 be the values of q, w, and ΔE for Case 1, and let q_2, w_2, and ΔE_2 be the values for Case 2. (**a**) What is the value of q_1? (**b**) What is the sign of w_1? (**c**) What is the sign of ΔE_1? (**d**) What is the sign of q_2? (**e**) Is the value of ΔE_2 greater than, equal to, or less than the value of ΔE_1? (**f**) Is the final state of the gas the same for both cases?



5.107 Limestone stalactites and stalagmites are formed in caves by the following reaction:

$$Ca^{2+}(aq) + 2\,HCO_3^-(aq) \longrightarrow CaCO_3(s) + CO_2(g) + H_2O(l)$$

If 1 mol of $CaCO_3$ forms at 298 K under 1 atm pressure, the reaction performs 2.47 kJ of P–V work, pushing back the atmosphere as the gaseous CO_2 forms. At the same time, 38.95 kJ of heat is absorbed from the environment. What are the values of ΔH and of ΔE for this reaction?

5.108 A house is designed to have passive solar energy features. Brickwork incorporated into the interior of the house acts as a heat absorber. Each brick weighs approximately 1.8 kg. The specific heat of the brick is 0.85 J/g-K. How many bricks must be incorporated into the interior of the house to provide the same total heat capacity as 1.7×10^3 gal of water?

5.109 A coffee-cup calorimeter of the type shown in Figure 5.18 contains 150.0 g of water at 25.1°C. A 121.0-g block of copper metal is heated to 100.4°C by putting it in a beaker of boiling water. The specific heat of Cu(s) is 0.385 J/g-K. The Cu is added to the calorimeter, and after a time the contents of the cup reach a constant temperature of 30.1°C. (**a**) Determine the amount of heat, in J, lost by the copper block. (**b**) Determine the amount of heat gained by the water. The specific heat of water is 4.18 J/g-K. (**c**) The difference between your answers for (**a**) and (**b**) is due to heat loss through the Styrofoam® cups and the heat necessary to raise the temperature of the inner wall of the apparatus. The heat capacity of the calorimeter is the amount of heat necessary to raise the temperature of the apparatus (the cups and the stopper) by 1 K. Calculate the heat capacity of the calorimeter in J/K. (**d**) What would be the final temperature of the system if all the heat lost by the copper block were absorbed by the water in the calorimeter?

5.110 Propylene glycol, $C_3H_8O_2$, is a viscous liquid used in the production of polyester resins. A 1.500-g sample of propylene glycol is combusted to $CO_2(g)$ and $H_2O(l)$ in a bomb calorimeter for which the total heat capacity is 6.355 kJ/°C. The temperature of the calorimeter increases from 22.45 to 28.10°C. (**a**) Write a balanced equation for the combustion of propylene glycol to $CO_2(g)$ and $H_2O(l)$. (**b**) How much heat is evolved during the combustion of the 1.500-g sample of propylene glycol? (**c**) Calculate the enthalpy change for the combustion of one mole of propylene glycol to $CO_2(g)$ and $H_2O(l)$. (**d**) What is the value of ΔH_f° for propylene glycol?

5.111 (**a**) When a 0.235-g sample of benzoic acid is combusted in a bomb calorimeter (Figure 5.19), the temperature rises 1.642°C. When a 0.265-g sample of caffeine, $C_8H_{10}N_4O_2$, is burned, the temperature rises 1.525°C. Using the value 26.38 kJ/g for the heat of combustion of benzoic acid, calculate the heat of combustion per mole of caffeine at constant volume. (**b**) Assuming that there is an uncertainty of 0.002°C in each temperature reading and that the masses of samples are measured to 0.001 g, what is the estimated uncertainty in the value calculated for the heat of combustion per mole of caffeine?

5.112 Meals-ready-to-eat (MREs) are military meals that can be heated on a flameless heater. The heat is produced by the following reaction:

$$Mg(s) + 2\,H_2O(l) \longrightarrow Mg(OH)_2(s) + 2\,H_2(g)$$

(**a**) Calculate the standard enthalpy change for this reaction. (**b**) Calculate the number of grams of Mg needed for this reaction to release enough energy to increase the temperature of 75 mL of water from 21 to 79°C.

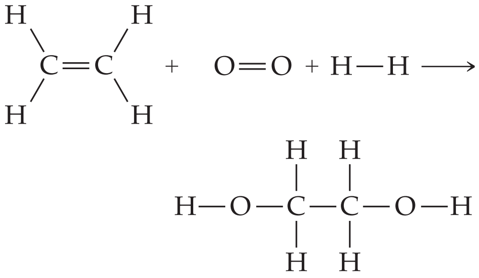
5.113 Burning methane in oxygen can produce three different carbon-containing products: soot (very fine particles of graphite), CO(g), and $CO_2(g)$. (**a**) Write three balanced equations for the reaction of methane gas with oxygen to produce these three products. In each case, assume that $H_2O(l)$ is the only other product. (**b**) Determine the standard enthalpies for the reactions in part (a). (**c**) For which of the three potential products is the magnitude of ΔH the largest?

5.114 Gaseous iodine pentafluoride, IF_5, can be prepared by the reaction of gaseous iodine and gaseous fluorine according to the following balanced equation:

$$I_2(g) + 5\,F_2(g) \rightarrow 2\,IF_5(g)$$

(**a**) The value of ΔH_f° for $IF_5(g)$ is -843 kJ/mol. Using this value and data in Appendix C, calculate ΔH° for the preceding reaction. (**b**) The IF_5 molecule has five I—F single bonds. Use your answer to part (a) and data in Table 5.4 to estimate the bond enthalpy D(I—F).

5.115 Use average bond enthalpies from Table 5.4 to estimate ΔH for the following gas-phase reaction of ethylene, (C_2H_4), oxygen, and hydrogen to form ethylene glycol ($C_2H_6O_2$), which is the principal component of automotive antifreeze:



5.116 Depending on their specific usage, fuels are judged in part on energy released per unit volume and energy released per unit mass. Three prospective fuels are listed in the following table, along with their densities and molar enthalpies of combustion. (**a**) Rank the three fuels according to their enthalpy produced per gram. (**b**) Rank them according to their enthalpy produced per cm^3:

Fuel	Density at 20°C (g/cm^3)	Molar Enthalpy of Combustion (kJ/mol)
Nitroethane, $C_2H_5NO_2(l)$	1.052	−1368
Ethanol, $C_2H_5OH(l)$	0.789	−1367
Methylhydrazine, $CH_6N_2(l)$	0.874	−1307

5.117 The hydrocarbons acetylene (C_2H_2) and benzene (C_6H_6) have the same empirical formula. Benzene is an "aromatic" hydrocarbon that is unusually stable because of its structure. (**a**) By using data in Appendix C, determine the standard enthalpy change for the reaction $3\,C_2H_2(g) \longrightarrow C_6H_6(l)$. (**b**) Which has greater enthalpy, 3 mol of acetylene gas or 1 mol of liquid benzene? (**c**) Determine the fuel value, in kJ/g, for acetylene and benzene.

5.118 (**a**) Ammonia (NH_3) boils at −33°C; at this temperature it has a density of 0.81 g/cm^3. The enthalpy of formation of $NH_3(g)$ is −46.2 kJ/mol, and the enthalpy of vaporization of $NH_3(l)$ is 23.2 kJ/mol. What is the enthalpy change when 1 L of liquid NH_3 is burned in air to give $N_2(g)$ and $H_2O(g)$? (**b**) Methanol, CH_3OH, is a liquid at room temperature, its density at 25 °C is 0.792 g/cm^3, and its $\Delta H_f^\circ = -239$ kJ/mol. What is the value of ΔH for the complete combustion of 1 L of liquid methanol to $CO_2(g)$ and $H_2O(g)$? (**c**) Based on the results of parts (a) and (b), which substance produces more heat per liter upon burning?

5.119 Three common hydrocarbons that contain four carbons are listed here, along with their standard enthalpies of formation:

Hydrocarbon	Formula	ΔH_f° (kJ/mol)
1,3-Butadiene	$C_4H_6(g)$	111.9
1-Butene	$C_4H_8(g)$	1.2
n-Butane	$C_4H_{10}(g)$	−124.7

(**a**) For each of these substances, calculate the molar enthalpy of combustion to $CO_2(g)$ and $H_2O(l)$. (**b**) Calculate the fuel value, in kJ/g, for each of these compounds. (**c**) For each hydrocarbon, determine the percentage of hydrogen by mass. (**d**) Based on your results, does the fuel value increase, stay the same, or decrease as the hydrogen content increases for these hydrocarbons?

5.120 The Sun supplies about 1.0 kilowatt of energy for each square meter of surface area (1.0 kW/m^2, where a watt = 1 J/s). Plants produce the equivalent of about 0.20 g of sucrose ($C_{12}H_{22}O_{11}$) per hour per square meter. Assuming that the sucrose is produced as follows, calculate the percentage of sunlight used to produce sucrose.

$$12\,CO_2(g) + 11\,H_2O(l) \longrightarrow C_{12}H_{22}O_{11} + 12\,O_2(g) \qquad \Delta H = 5645\text{ kJ}$$

5.121 At 20°C (approximately room temperature), the average velocity of N_2 molecules in air is 1050 mph. (**a**) What is the average speed in m/s? (**b**) What is the kinetic energy (in J) of an N_2 molecule moving at this speed? (**c**) What is the total kinetic energy of 1 mol of N_2 molecules moving at this speed?

5.122 Consider two solutions: 50.0 mL of 1.00 M $CuSO_4$ and 50.0 mL of 2.00 M KOH. When the two solutions are mixed in a constant-pressure calorimeter, a precipitate forms and the temperature of the mixture rises from 21.5 to 27.7°C. (**a**) Before mixing, how many grams of Cu are present in the solution of $CuSO_4$? (**b**) Predict the identity of the precipitate in the reaction. (**c**) Write complete and net ionic equations for the reaction that occurs when the two solutions are mixed. (**d**) From the calorimetric data, calculate ΔH for the reaction that occurs on mixing. Assume that the calorimeter absorbs only a negligible quantity of heat, that the total volume of the solution is 100.0 mL, and that the specific heat and density of the solution after mixing are the same as those of pure water.

Design an Experiment

One of the important ideas of thermodynamics is that energy can be transferred in the form of heat or work. Imagine that you lived 180 years ago when the relationships between heat and work were not well understood. You have formulated a hypothesis that work can be converted to heat, with the same amount of work always generating the same amount of heat. To test this idea, you have designed an experiment using a device in which a falling weight is connected through pulleys to a shaft with an attached paddle wheel that is immersed in water. This is actually a classic experiment performed by James Joule in the 1840s. You can see various images of Joule's apparatus by searching the internet for "Joule experiment images."

(**a**) Using this device, what measurements would you need to make to test your hypothesis? (**b**) What equations would you use in analyzing your experiment? (**c**) Do you think you could obtain a reasonable result from a single experiment? Why or why not? (**d**) In what way could the precision of your instruments affect the conclusions that you make? (**e**) List ways that you could modify the equipment to improve the data you obtain if you were performing this experiment today instead of 180 years ago. (**f**) Give an example of how you could demonstrate the relationship between heat and a form of energy other than mechanical work.

6

ELECTRONIC STRUCTURE OF ATOMS

▲ **THE AURORA BOREALIS OR NORTHERN LIGHTS** offer a brilliant display of color in the night sky. They result when ionized particles in the solar wind, mostly electrons and protons, excite atoms and molecules in the atmosphere. Light is produced when electrons in these excited atoms lose energy and fall back to their ground-state orbitals.

In this chapter, we explore *quantum theory*, which explains many aspects of the behavior of electrons in atoms, molecules, and all other forms of matter. We begin by looking at the nature of light and how our description of light was changed by quantum theory. We explore some of the tools used in *quantum mechanics*, a field developed in the first half of the twentieth century to describe the **electronic structure** of atoms—a term that refers to the number of electrons in the atom as well as their distribution around the nucleus and their energies. We will show that the quantum description of the electronic structure of atoms not only helps us to understand the arrangement of the elements in the periodic table, but also helps us understand why, for example, helium and neon are unreactive gases, whereas sodium and potassium are soft, reactive metals.

WHAT'S AHEAD

6.1 ▶ The Wave Nature of Light Learn that light (radiant energy, or *electromagnetic radiation*) has wave-like properties and is characterized by *wavelength*, *frequency*, and *speed*.

6.2 ▶ Quantized Energy and Photons Recognize that electromagnetic radiation also has particle-like properties and can be described as "particles" of light called *photons*.

6.3 ▶ Line Spectra and the Bohr Model Examine the light emitted by electrically excited atoms (*line spectra*), observations that led to the Bohr model of the atom.

6.4 ▶ The Wave Behavior of Matter Recognize that matter also has wave-like properties. As a result, it is impossible to determine simultaneously the exact position and the exact momentum of an electron in an atom (*Heisenberg's uncertainty principle*).

6.5 ▶ Quantum Mechanics and Atomic Orbitals Describe the behavior of the electron in a hydrogen atom by treating it as a wave. The *wave functions* that mathematically describe the electron's position and energy in an atom define *atomic orbitals*.

6.6 ▶ Representations of Orbitals Examine the sizes and shapes of orbitals and how they can be represented by graphs of electron density.

6.7 ▶ Many-Electron Atoms Learn that the energy levels of an atom having more than one electron are different from those of the hydrogen atom, and that each electron has an additional quantum-mechanical property called *spin*.

6.8 ▶ Electron Configurations Learn how the orbitals of the hydrogen atom can be used to describe the arrangements of electrons in many-electron atoms.

6.9 ▶ Electron Configurations and the Periodic Table Recognize that the electron configuration of an atom is related to the location of the element in the periodic table.

6.1 | The Wave Nature of Light

Learning Objectives

When you finish Section 6.1, you should be able to:

- Identify the different types of electromagnetic radiation and arrange them in order of their relative wavelength or frequency.
- Calculate the frequency of electromagnetic radiation from its wavelength and vice versa.

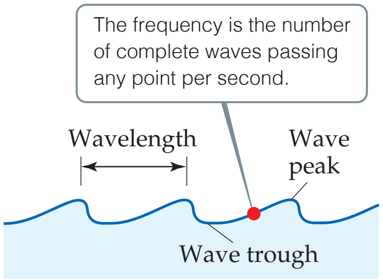
Much of our present understanding of the electronic structure of atoms and molecules has come from analysis of the light either emitted or absorbed by substances. To understand the way electrons behave in various substances, therefore, we must first learn more about light. In this section we learn about the wave-like properties of light.

A wave is a propagating disturbance that travels through a medium, transporting energy as it moves through the medium. When you drop a stone into a still pond, the energy of the collision is dispersed by vertical displacements of water molecules that lead to the familiar pattern of waves that emanate outward from the point of entry (**Figure 6.1**). Though less obvious, light can also be thought of as a wave of propagating energy. A light wave is made up of oscillating electric and magnetic fields, and thus it is referred to as **electromagnetic radiation**. Because electromagnetic radiation carries energy through space, it is also known as *radiant energy*.

▲ **Figure 6.1 Water waves** are generated when an object is dropped into a pool of still water. The regular variation of peaks and troughs enables us to sense the motion of the waves as energy is dispersed from the point where the object impacted the water.

There are many types of electromagnetic radiation in addition to visible light. These different types—radio waves, infrared radiation (heat), ultraviolet radiation, X rays—may seem very different from one another, but they all share certain fundamental characteristics.

All types of electromagnetic radiation move through a vacuum at 2.998×10^8 m/s, the *speed of light*. All have wave-like characteristics similar to those of waves that move through water. A cross section of a water wave (**Figure 6.2**) shows that it is *periodic*, which means that the pattern of peaks and troughs repeats itself at regular intervals. The distance between two adjacent peaks (or between two adjacent troughs) is called the **wavelength**. The number of complete wavelengths, or *cycles*, that pass a given point each second is the **frequency** of the wave.



The frequency is the number of complete waves passing any point per second.
Wavelength
Wave peak
Wave trough

▲ **Figure 6.2 Water waves.** The *wavelength* is the distance between two adjacent peaks or two adjacent troughs.

Just as with water waves, we can assign a frequency and wavelength to electromagnetic waves, as illustrated in **Figure 6.3**. These and all other wave characteristics of electromagnetic radiation are due to the periodic oscillations in the intensities of the electric and magnetic fields associated with the radiation.

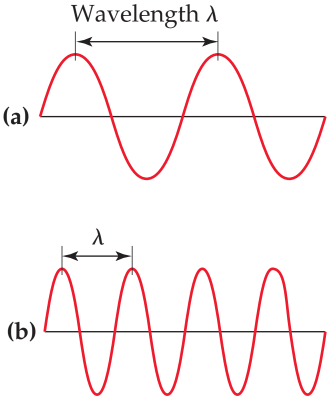
The speed of water waves can vary depending on how they are created. For example, the waves produced by a speed boat travel faster than those produced by a rowboat. In contrast, *all electromagnetic radiation moves at the same speed—namely, the speed of light*. As a result, the wavelength and frequency of electromagnetic radiation are always related in a straightforward way. If the wavelength is long, fewer cycles of the wave pass a given point per second, and so the frequency is low. Conversely, for a wave to have a high frequency, it must have a short wavelength. This inverse relationship between the frequency and wavelength of electromagnetic radiation is expressed by the equation

$$\lambda\nu = c \qquad [6.1]$$

where λ (lambda) is wavelength, ν (nu) is frequency, and c is the speed of light.

Go Figure

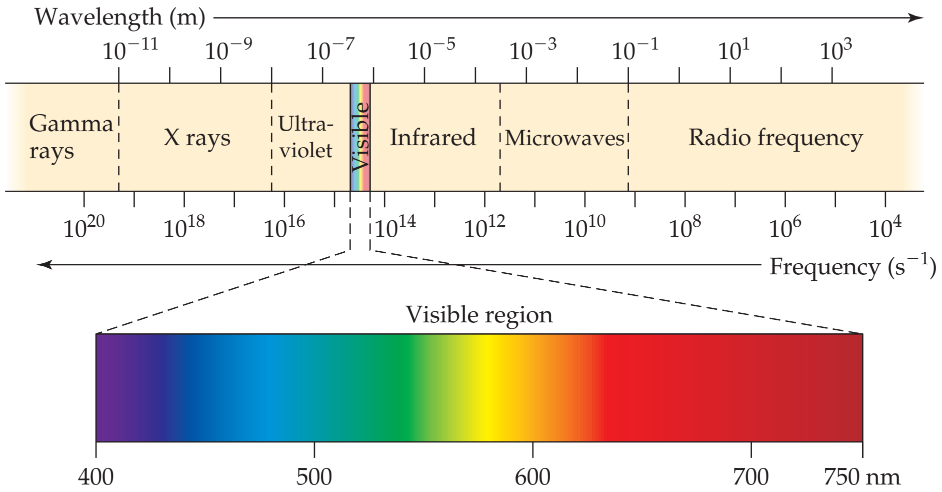
If wave (a) has a wavelength of 2.0 m and a frequency of 1.5×10^8 cycles/s, what are the wavelength and frequency of wave (b)?



▲ **Figure 6.3 Electromagnetic waves.** Like water waves, electromagnetic radiation can be characterized by a wavelength. As the wavelength, λ, decreases, the frequency, ν, increases. The wavelength in (**b**) is *half* as long as that in (**a**), so the frequency of the wave in (**b**) is *twice* as great as that in (**a**).

Go Figure

Is the wavelength of a microwave longer or shorter than the wavelength of visible light? By how many orders of magnitude do the two waves differ in wavelength?



▲ **Figure 6.4 The electromagnetic spectrum.** Wavelengths in the spectrum range from very short gamma rays to very long radio waves.

Figure 6.4 shows the various types of electromagnetic radiation arranged in order of increasing wavelength, a display called the *electromagnetic spectrum*. The wavelengths span an enormous range. The wavelengths of gamma rays are comparable to the diameters of atomic nuclei, whereas the wavelengths of radio waves can be longer than a football field. Visible light (the light we can see with our eyes), which corresponds to wavelengths of about 400 to 750 nm (4.00×10^{-7} to 7.50×10^{-7} m), is an extremely small portion of the electromagnetic spectrum. The unit of length chosen to express wavelength depends on the type of radiation, as shown in **Table 6.1**.

Frequency is expressed in cycles per second, a unit also called a *hertz* (Hz). Because it is understood that cycles are involved, the units of frequency are normally given simply as "per second," which is denoted by s^{-1} or /s. For example, a frequency of 698 megahertz (MHz), a typical frequency for a cellular telephone, could be written as 698 MHz, 698,000,000 Hz, 698,000,000 s^{-1} or 698,000,000/s.

TABLE 6.1 Common Wavelength Units for Electromagnetic Radiation

Unit	Symbol	Length (m)	Type of Radiation
Angstrom	Å	10^{-10}	X ray
Nanometer	nm	10^{-9}	Ultraviolet, visible
Micrometer	μm	10^{-6}	Infrared
Millimeter	mm	10^{-3}	Microwave
Centimeter	cm	10^{-2}	Microwave
Meter	m	1	Television, radio
Kilometer	km	10^{3}	Radio

Sample Exercise 6.1

Calculating Frequency from Wavelength

The yellow light given off by a sodium vapor lamp used for public lighting has a wavelength of 589 nm. What is the frequency of this radiation?

SOLUTION

Analyze We are given the wavelength, λ, of the radiation and asked to calculate its frequency, ν.

Plan The relationship between the wavelength and the frequency is given by Equation 6.1. We can solve for ν and use the values of λ and c to obtain a numerical answer. (The speed of light, c, is 3.00×10^8 m/s to three significant figures.)

Solve Solving Equation 6.1 for frequency gives $\nu = c/\lambda$. When we insert the values for c and λ, we note that the units of length in these

Continued

two quantities are different. We use a conversion factor to convert the wavelength from nanometers to meters, so the units cancel:

$$\nu = \frac{c}{\lambda} = \left(\frac{3.00 \times 10^{8}\ \cancel{\text{m}}/\text{s}}{589\ \cancel{\text{nm}}}\right)\left(\frac{1\ \cancel{\text{nm}}}{10^{-9}\ \cancel{\text{m}}}\right)$$
$$= 5.09 \times 10^{14}\ \text{s}^{-1}$$

Check The high frequency is reasonable because of the short wavelength. The units are proper because frequency has units of “per second,” or s^{-1}.

▶ Practice Exercise

(**a**) A laser used in orthopedic spine surgery produces radiation with a wavelength of 2.10 μm. Calculate the frequency of this radiation. (**b**) An FM radio station broadcasts electromagnetic radiation at a frequency of 103.4 MHz (megahertz; 1 MHz $= 10^{6}\ s^{-1}$). Calculate the wavelength of this radiation. The speed of light is 2.998×10^{8} m/s to four significant figures.

Self-Assessment Exercises

SAE 6.1 If an electromagnetic wave has a frequency of $1.5 \times 10^{10}\ s^{-1}$, it falls in the ________ region of the electromagnetic spectrum, and its wavelength is ________. (**a**) radio frequency, 50 m (**b**) radio frequency, 2.0 cm (**c**) microwave, 50 m (**d**) microwave, 2.0 cm (**e**) gamma ray, 6.7×10^{-11} m

SAE 6.2 Which of the following statements is or are true?

(**i**) Microwaves have a higher frequency than X rays.
(**ii**) Microwaves have a longer wavelength than X rays.
(**iii**) Microwaves travel through a vacuum faster than X rays.

(**a**) only i (**b**) only ii (**c**) both i and iii (**d**) both ii and iii (**e**) All three statements are true.

6.2 | Quantized Energy and Photons

Learning Objectives

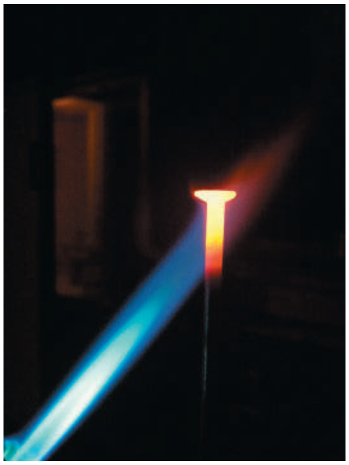
When you finish Section 6.2, you should be able to:

- ▶ Explain how blackbody radiation and the photoelectric effect provide evidence that electromagnetic radiation is quantized.
- ▶ Describe electromagnetic radiation as particles called photons and calculate the energy of a photon from either its frequency or its wavelength.

Although the wave model of light explains many aspects of the behavior of light, several observations cannot be resolved by this model. Three of these observations are particularly pertinent to our understanding of how electromagnetic radiation and atoms interact: (1) the emission of light from hot objects (referred to as *blackbody radiation* because the objects studied appear black before heating), (2) the emission of electrons from metal surfaces on which light shines (the *photoelectric effect*), and (3) the emission of light from electronically excited gas atoms (*emission spectra*). These deviations from wave-like behavior led to the development of quantum theory in the early part of the twentieth century. This was a revolutionary advance that changed the way scientists understood both light and matter. In this section we examine the first two phenomena; emission spectra are examined in Section 6.3.

Go Figure

Which is at a higher temperature: the part of the nail glowing yellow or the part glowing red?



▲ **Figure 6.5 Color and temperature.** The color and intensity of the light emitted by a hot object, such as this nail, depend on the temperature of the object.

Hot Objects and the Quantization of Energy

When solids are heated, they emit radiation, as seen in the red glow of an electric stove burner or the bright white light of a tungsten light bulb. The wavelength distribution of the radiation depends on temperature; a red-hot object, for instance, is cooler than a yellowish or white-hot one (**Figure 6.5**). During the late 1800s, a number of physicists studied this phenomenon, trying to understand the relationship between the temperature and the intensity and wavelength of the emitted radiation. The prevailing laws of physics could not account for the observations.

In 1900, the German physicist Max Planck (1858–1947) solved the problem by making a daring assumption: He proposed that energy can be either released or absorbed by atoms only in discrete “chunks” of some minimum size. Planck gave the name **quantum** (meaning “fixed amount”) to the smallest quantity of energy that can be emitted or absorbed as electromagnetic radiation. He proposed that the energy, E, of a single quantum is equal to a constant times the frequency of the radiation:

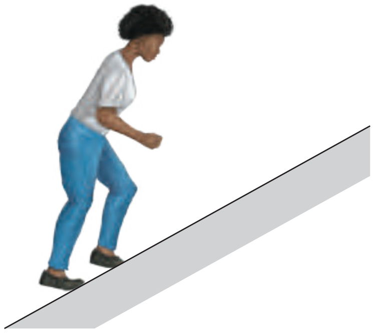
$$E = h\nu \qquad [6.2]$$

The proportionality constant h is called the **Planck constant** and has a value of 6.626×10^{-34} joule-second (J-s).

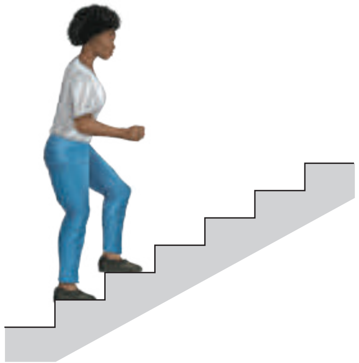
According to Planck's theory, matter can emit and absorb energy only in whole-number multiples of $h\nu$. If the quantity of energy emitted by an atom is $3h\nu$, for example, then we say that three quanta of energy have been emitted (*quanta* being the plural of *quantum*). Because the energy can be released only in specific amounts, we say that the allowed energies are *quantized*—their values are restricted to certain quantities. Planck's revolutionary proposal that energy is quantized proved to be correct, and he was awarded the 1918 Nobel Prize in Physics for his work on quantum theory.

If the notion of quantized energies seems strange, consider the difference between a ramp and a staircase (**Figure 6.6**). As you walk up a ramp, your potential energy increases in a uniform, continuous manner. When you climb a staircase, you can step only *on* individual stairs, not *between* them, so the increase in your potential energy is restricted to certain values and is therefore quantized.

If Planck's quantum theory is correct, why are its effects not obvious in our daily lives? Why do energy changes seem continuous rather than quantized, or "jagged"? The Planck constant is an extremely small number, so a quantum of energy, $h\nu$, is an extremely small quantity. Planck's rules regarding the gain or loss of energy are always the same, whether we are concerned with objects on the scale of our ordinary experience or with microscopic objects. With everyday objects, however, the gain or loss of a single quantum of energy is so small that it goes completely unnoticed. In contrast, when dealing with matter at the atomic level, the impact of quantized energies is far more significant.



Potential energy of person walking up ramp increases in uniform, continuous manner



Potential energy of person walking up steps increases in stepwise, quantized manner

▲ **Figure 6.6** **Quantized versus continuous change in energy.**

The Photoelectric Effect and Photons

A few years after Planck presented his quantum theory, scientists began to see its applicability to many experimental observations. In 1905, Albert Einstein (1879–1955) used Planck's theory to explain the **photoelectric effect** (**Figure 6.7**). Light shining on a clean metal surface causes electrons to be emitted from the surface. A minimum frequency of light, different for different metals, is required for the emission of electrons. For example, light with a frequency of $4.60 \times 10^{14}\ \text{s}^{-1}$ or greater causes cesium metal to emit electrons, but if the light has frequency less than that, no electrons are emitted.

To explain the photoelectric effect, Einstein assumed that the radiant energy striking the metal surface behaves like a stream of tiny energy packets. Each packet, which is like a "particle" of energy, is called a **photon**. Extending Planck's quantum theory, Einstein deduced that each photon must have an energy equal to the Planck constant times the frequency of the light:

$$\text{Energy of photon, } E = h\nu \qquad [6.3]$$

Thus, radiant energy itself is quantized.

Under the right conditions, photons striking a metal surface can transfer their energy to electrons in the metal. A certain amount of energy—called the *work function*—is required for the electrons to overcome the attractive forces holding them in the metal. If the photons striking the metal have less energy than the work function, the electrons do not acquire sufficient energy to escape from the metal. Increasing the intensity of the light source doesn't lead to emission of electrons from the metal, but increasing the frequency of the incoming light can have that effect. We can understand this behavior if we think of light as being made up of photons with quantized energies. When the intensity (brightness) of the light is increased, the number of photons striking the surface per unit time increases, but the energy of each photon remains unchanged. When the frequency is increased, the energy of each photon increases, and when that energy is greater than the work function of a particular metal, electrons are emitted and the excess energy of the photon is converted into kinetic energy of the emitted electron. Einstein won the Nobel Prize in Physics in 1921 primarily for his explanation of the photoelectric effect.

To better understand what a photon is, imagine you have a light source that produces radiation of a single wavelength. Further suppose that you could switch the light on and off faster and faster to provide ever-smaller bursts of energy. Einstein's photon theory tells us that you would eventually come to the smallest energy burst, given by $E = h\nu$. This smallest burst consists of a single photon of light.

Go Figure

If the frequency of the incoming light is increased, will the energy of the ejected electrons increase, decrease, or stay the same?

Sample Exercise 6.2

Energy of a Photon

Calculate the energy of one photon of yellow light that has a wavelength of 589 nm.

SOLUTION

Analyze Our task is to calculate the energy, E, of a photon, given its wavelength, $\lambda = 589\ \text{nm}$.

Plan We can use Equation 6.1 to convert the wavelength to frequency: $\nu = c/\lambda$. We can then use Equation 6.3 to calculate the energy of the photon: $E = h\nu$.

Solve The frequency, ν, is calculated from the given wavelength, as shown in Sample Exercise 6.1:

$$\nu = (3.00 \times 10^{8}\ \cancel{\text{m}}/\text{s})/(589 \times 10^{-9}\ \cancel{\text{m}}) = 5.09 \times 10^{14}\ \text{s}^{-1}$$

The value of the Planck constant, h, is given both in the text and in the table of physical constants on the inside back cover of the text; thus, we can calculate E:

$$E = (6.626 \times 10^{-34}\ \text{J-}\cancel{\text{s}})(5.09 \times 10^{14}\ \cancel{\text{s}^{-1}}) = 3.37 \times 10^{-19}\ \text{J}$$

Comment If one photon of radiant energy supplies $3.37 \times 10^{-19}\ \text{J}$, we calculate that one mole of these photons will supply:

$$(6.022 \times 10^{23}\ \cancel{\text{photons}}/\text{mol})(3.37 \times 10^{-19}\ \text{J}/\cancel{\text{photon}}) = 2.03 \times 10^{5}\ \text{J/mol}$$

Practice Exercise

(**a**) A laser emits light that has a frequency of $4.69 \times 10^{14}\ \text{s}^{-1}$. What is the energy of one photon of this radiation? (**b**) If the laser emits a pulse containing 5.0×10^{17} photons of this radiation, what is the total energy of that pulse? (**c**) If the laser emits $1.3 \times 10^{-2}\ \text{J}$ of energy during a pulse, how many photons are emitted?

The idea that the energy of light depends on its frequency helps us understand the diverse effects that different kinds of electromagnetic radiation have on matter. For example, because of their high frequency (short wavelength), photons of ultraviolet light possess more energy than photons of visible light (Figure 6.4). This explains why prolonged exposure to ultraviolet light causes tissue damage that can in some cases lead to skin cancer. X rays have much higher frequencies still, and the high energies of X-ray photons allow them to pass through the soft tissues of our bodies, an attribute that permits X rays to be used to image our bones and teeth. It also explains why medical and dental technicians take precautions to minimize their own and their patients' exposure to such high-energy photons.

Although Einstein's theory of light as a stream of photons rather than a wave explains the photoelectric effect and a great many other observations, it also poses a dilemma. Is light a wave, or does it consist of particles? The only way to resolve this dilemma is to adopt what might seem to be a bizarre position: We must consider that light possesses both wave-like and particle-like characteristics and, depending on the situation, will behave more like waves or more like particles. We will soon see that this dual wave-particle nature is also a characteristic trait of matter.

Self-Assessment Exercises

SAE 6.3 The work function of silver metal is $6.9 \times 10^{-19}\ \text{J}$. If a crystal of silver is exposed to a pulse of blue light with a wavelength of 450 nm, will electrons be ejected, and if so, what is the maximum kinetic energy they can have? (**a**) Electrons will not be ejected. (**b**) Electrons with a maximum kinetic energy of $4.4 \times 10^{-19}\ \text{J}$ will be ejected. (**c**) Electrons with a maximum kinetic energy of $6.9 \times 10^{-19}\ \text{J}$ will be ejected. (**d**) Electrons with a maximum kinetic energy of $2.5 \times 10^{-19}\ \text{J}$ will be ejected.

SAE 6.4 Which form of electromagnetic radiation has the lowest energy photons? (**a**) ultraviolet light (**b**) infrared light (**c**) green light (**d**) red light

SAE 6.5 A laser gives off a pulse of infrared light with a wavelength of 1054 nm and a total energy of 2.5 J. How many photons are in this pulse of electromagnetic radiation?

(**a**) 1.3×10^{19} photons

(**b**) 1.9×10^{-19} photons

(**c**) 2.4×10^{6} photons

(**d**) 5.3×10^{18} photons

6.3 | Line Spectra and the Bohr Model

The work of Planck and Einstein paved the way for understanding how electrons are arranged in atoms. In 1913, the Danish physicist Niels Bohr (**Figure 6.8**) offered a theoretical explanation of the *line spectrum* of the hydrogen atom, another phenomenon that had puzzled scientists during the nineteenth century.

Learning Objectives

When you finish Section 6.3, you should be able to:

- Explain the Bohr model of the hydrogen atom and use it to account for the line spectrum of hydrogen.
- Use the Bohr model to calculate the wavelengths (or frequencies) of light that can either be absorbed or emitted by the hydrogen atom.

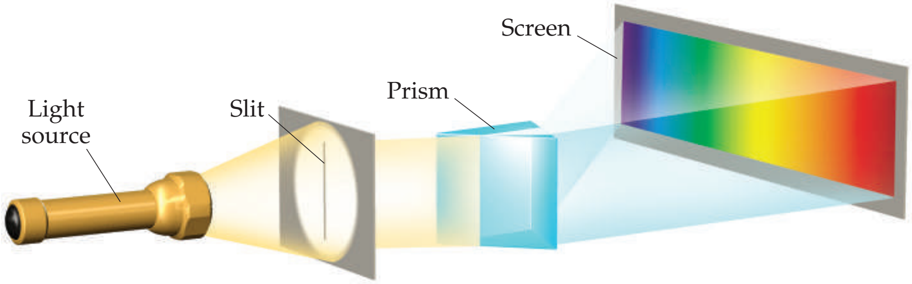
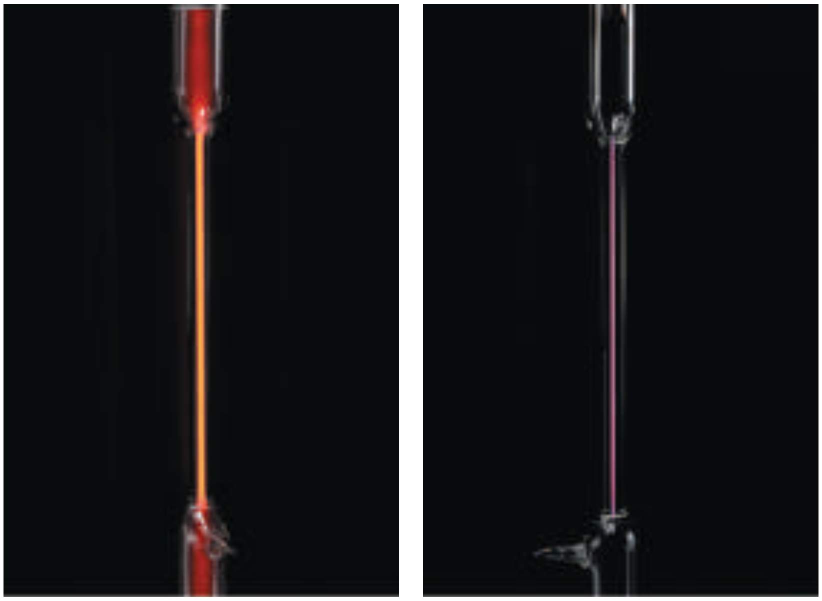
Line Spectra

A particular source of radiant energy may emit a single wavelength, as in the light from a laser. Radiation composed of a single wavelength is *monochromatic*. However, most common radiation sources, including incandescent light bulbs and stars, produce radiation containing many different wavelengths—that is, *polychromatic* radiation. A **spectrum** is produced when radiation from a polychromatic source is separated into its component wavelengths, as shown in **Figure 6.9**. The resulting spectrum consists of a continuous range of colors—violet merges into indigo, indigo into blue, and so forth, with no (or very few) blank spots. This rainbow of colors, containing light of all wavelengths, is called a **continuous spectrum**. The most familiar example of a continuous spectrum is the rainbow produced when raindrops or mist acts as a prism for sunlight.

Not all radiation sources produce a continuous spectrum. When a high voltage is applied to tubes that contain different gases under reduced pressure, the gases emit different colors of light (**Figure 6.10**). The light emitted by neon gas is the familiar red-orange glow of many "neon" lights, whereas sodium vapor emits the yellow light characteristic of some modern streetlights. When light coming from such tubes is passed through a

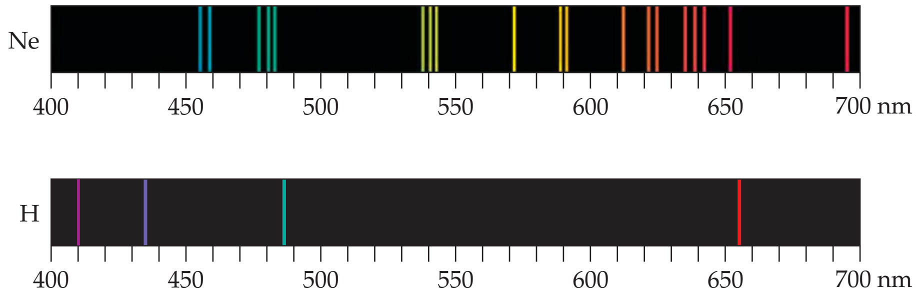


◀ **Figure 6.9 Creating a spectrum.** A continuous visible spectrum is produced when a narrow beam of white light is passed through a prism. The white light could be sunlight or light from an incandescent lamp.



Neon (Ne) Hydrogen (H)

◀ **Figure 6.10 Atomic emission of neon and hydrogen.** Different gases emit light of different characteristic colors when an electric current is passed through them.



▲ **Figure 6.11 Line spectra of neon and hydrogen.** The colored lines occur at wavelengths present in the emission. The black regions are wavelengths for which no light is produced in the emission.

prism, only a few wavelengths are present in the resultant spectra (**Figure 6.11**). Each colored line in such spectra represents light of one wavelength. A spectrum containing radiation of only specific wavelengths is called a **line spectrum.**

When scientists first detected the line spectrum of hydrogen in the mid-1800s, they were fascinated by its simplicity. At that time, only four lines at wavelengths of 410 nm (violet), 434 nm (blue), 486 nm (blue-green), and 656 nm (red) were observed (Figure 6.11). In 1885, a Swiss schoolteacher named Johann Balmer showed that the wavelengths of these four lines fit an intriguingly simple formula that relates the wavelengths to integers. Later, additional lines were found in the ultraviolet and infrared regions of hydrogen's line spectrum. Soon Balmer's equation was extended to a more general one, called the *Rydberg equation*, which allows us to calculate the wavelengths of all the spectral lines of hydrogen:

$$\frac{1}{\lambda} = (R_H)\left(\frac{1}{n_1^2} - \frac{1}{n_2^2}\right) \qquad [6.4]$$

In this formula, λ is the wavelength of a spectral line, R_H is the *Rydberg constant* ($1.096776 \times 10^7\ m^{-1}$), and n_1 and n_2 are positive integers, with n_2 being larger than n_1. How could the remarkable simplicity of this equation be explained? It took nearly 30 more years to answer this question.

Bohr's Model

Rutherford's discovery of the nuclear atom (Section 2.2) suggested that an atom might be thought of as a "microscopic solar system" in which the electrons orbit the nucleus. To explain the line spectrum of hydrogen, Bohr assumed that electrons in hydrogen atoms move in circular orbits around the nucleus, but this assumption posed a problem. According to classical physics, a charged particle (such as an electron) moving in a circular path should continuously lose energy. As an electron loses energy, therefore, it should spiral into the positively charged nucleus. This behavior, however, does not happen—hydrogen atoms are stable. So how can we explain this apparent violation of the laws of physics? Bohr approached this problem in much the same way that Planck had approached the problem of the nature of the radiation emitted by hot objects: He assumed that the prevailing laws of physics were inadequate to describe all aspects of atoms. Furthermore, he adopted Planck's idea that energies are quantized.

Bohr based his model on three postulates:

1. Only orbits of certain radii, corresponding to certain specific energies, are permitted for the electron in a hydrogen atom.
2. An electron in a permitted orbit is in an "allowed" energy state. An electron in an allowed energy state does not radiate energy and, therefore, does not spiral into the nucleus.
3. Energy is emitted or absorbed by the electron only as the electron changes from one allowed energy state to another. This energy is emitted or absorbed as a photon that has energy $E = h\nu$.

The Energy States of the Hydrogen Atom

Starting with his three postulates and using classical equations for motion and for interacting electrical charges, Bohr calculated the energies corresponding to the allowed orbits for the electron in the hydrogen atom. Ultimately, the calculated energies fit the formula

$$E = (-hcR_H)\left(\frac{1}{n^2}\right) = (-2.18 \times 10^{-18}\,\mathrm{J})\left(\frac{1}{n^2}\right) \qquad [6.5]$$

where h, c, and R_H are the Planck constant, the speed of light, and the Rydberg constant, respectively. The integer n, which can have whole-number values of 1, 2, 3, ..., ∞, is called the **principal quantum number**.

Each allowed orbit corresponds to a different value of n. The radius of the orbit gets larger as n increases. Thus, the first allowed orbit (the one closest to the nucleus) has $n = 1$, the next allowed orbit (the one second closest to the nucleus) has $n = 2$, and so forth. The electron in the hydrogen atom can be in any allowed orbit, and Equation 6.5 tells us the energy of the electron in that orbit.

The energies of the electron given by Equation 6.5 are negative for all values of n. The lower (more negative) the energy is, the more stable the atom. The energy is lowest (most negative) for $n = 1$. As n gets larger, the energy becomes less negative and therefore increases. We can liken the situation to a ladder in which the rungs are numbered from the bottom. The higher you climb (the greater the value of n), the higher the energy. The lowest-energy state ($n = 1$ analogous to the bottom rung) is called the **ground state** of the atom. When the electron is in a higher-energy state ($n = 2$ or higher), the atom is said to be in an **excited state**. Figure 6.12 shows the allowed energy levels for the hydrogen atom for several values of n.

What happens as n becomes infinitely large? The radius increases and the energy of attraction between the electron and the nucleus approaches zero, so when $n = \infty$ the electron is completely separated from the nucleus and the energy of the electron is zero:

$$E = (-2.18 \times 10^{-18}\,\mathrm{J})\left(\frac{1}{\infty^2}\right) = 0$$

The state in which the electron is completely separated from the nucleus is called the *reference*, or zero-energy, state of the hydrogen atom. Completely separating the electron from the nucleus corresponds to *ionizing* the hydrogen atom, a concept we return to in Chapter 7.

In his third postulate, Bohr assumed that the electron can "jump" from one allowed orbit to another by either absorbing or emitting photons whose radiant energy corresponds exactly to the energy difference between the two orbits. The electron must absorb energy in order to move to a higher-energy state (higher value of n). Conversely, radiant energy is emitted when the electron jumps to a lower-energy state (lower value of n).

Imagine a case in which the electron jumps from an initial state with principal quantum number n_i and energy E_i to a final state with principal quantum number n_f and energy E_f. Applying Equation 6.5, we see that the change in energy for this transition is

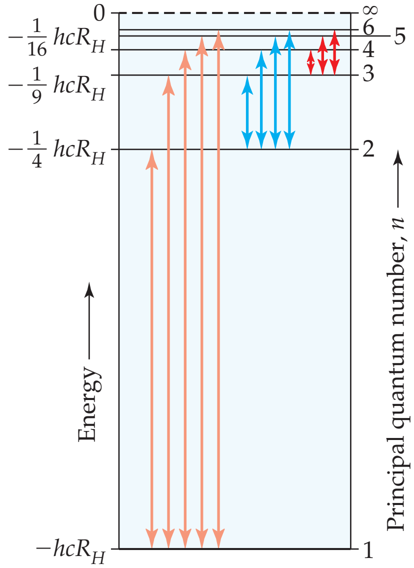
$$\Delta E = E_f - E_i = (-2.18 \times 10^{-18}\,\mathrm{J})\left(\frac{1}{n_f^2} - \frac{1}{n_i^2}\right) \qquad [6.6]$$

What is the significance of the *sign* of ΔE? Notice that ΔE is positive when n_f is greater than n_i, which happens when the electron jumps to a higher-energy orbit. Conversely, ΔE is negative when n_f is less than n_i, which happens when the electron falls in energy to a lower-energy orbit.

As noted previously, transitions from one allowed state to another will involve a photon. *The energy of the photon* (E_{photon}) *must equal the difference in energy between the two states* (ΔE). When ΔE is positive, a photon must be *absorbed* as the electron jumps to a higher energy. When ΔE is negative, a photon is *emitted* as the electron falls to a lower-energy level. In both cases, the energy of the photon must match the energy difference between the states. Because the frequency ν is always a positive number, the energy

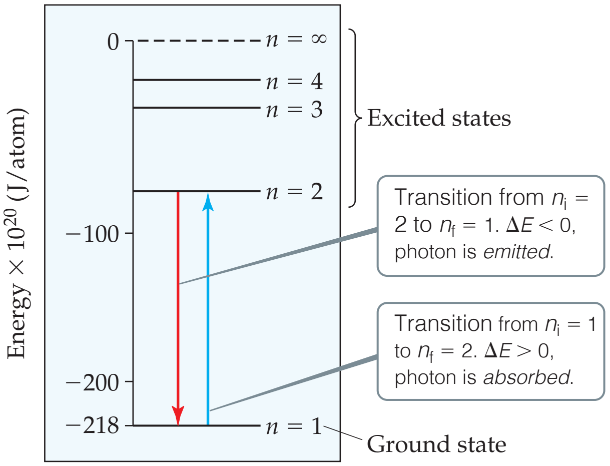
Go Figure

If the transition of an electron from the $n = 3$ state to the $n = 2$ state results in emission of visible light, is the transition from the $n = 2$ state to the $n = 1$ state more likely to result in the emission of infrared or ultraviolet radiation?



▲ **Figure 6.12 Energy levels in the hydrogen atom from the Bohr model.** The arrows refer to the transitions of the electron from one allowed energy state to another. The states shown are those for which $n = 1$ through $n = 6$ and the state for $n = \infty$ for which the energy, E, equals zero.

Go Figure Which transition will lead to the emission of light with longer wavelength, $n = 3$ to $n = 2$ or $n = 4$ to $n = 3$?



Transition from n_i = 2 to n_f = 1. $\Delta E < 0$, photon is *emitted*.

Transition from n_i = 1 to n_f = 2. $\Delta E > 0$, photon is *absorbed*.

▲ **Figure 6.13** **Change in energy states for absorption and emission of a photon in a hydrogen atom.**

of the photon ($h\nu$) must always be positive. Thus, the sign of ΔE tells us whether the photon is absorbed or emitted:

$$\Delta E > 0\ (n_f > n_i)\text{: Photon } \textit{absorbed} \text{ with } E_{\text{photon}} = h\nu = \Delta E$$

$$\Delta E < 0\ (n_f < n_i)\text{: Photon } \textit{emitted} \text{ with } E_{\text{photon}} = h\nu = -\Delta E \qquad [6.7]$$

These two situations are summarized in **Figure 6.13**. We see that Bohr's model of the hydrogen atom leads to the conclusion that only the specific frequencies of light that satisfy Equation 6.7 can be absorbed or emitted by the atom.

Let's see how to apply these concepts by considering a transition in which the electron moves from $n_i = 3$ to $n_f = 1$. From Equation 6.6 we have

$$\Delta E = (-2.18 \times 10^{-18}\,\text{J})\left(\frac{1}{1^2} - \frac{1}{3^2}\right) = (-2.18 \times 10^{-18}\,\text{J})\left(\frac{8}{9}\right) = -1.94 \times 10^{-18}\,\text{J}$$

The value of ΔE is negative, as you should expect for an electron that is falling from a higher-energy orbit ($n = 3$) to a lower-energy orbit ($n = 1$). A photon is *emitted* during this transition, and the energy of the photon is equal to $E_{\text{photon}} = h\nu = -\Delta E = +1.94 \times 10^{-18}$ J.

Knowing the energy of the emitted photon, we can calculate either its frequency or its wavelength. For the wavelength, we combine Equations 6.1 ($\lambda = c/\nu$) and 6.3 ($E_{\text{photon}} = h\nu$) to obtain

$$\lambda = \frac{c}{\nu} = \frac{hc}{E_{\text{photon}}} = \frac{hc}{-\Delta E} = \frac{(6.626 \times 10^{-34}\,\cancel{\text{J-s}})(2.998 \times 10^{8}\,\text{m}/\cancel{\text{s}})}{+1.94 \times 10^{-18}\,\cancel{\text{J}}} = 1.02 \times 10^{-7}\,\text{m}$$

Thus, a photon of wavelength 1.02×10^{-7} m (102 nm) is *emitted*.

We are now in a position to understand the remarkable simplicity of the line spectra of hydrogen, first discovered by Balmer. The line spectra are the result of emission, so $E_{\text{photon}} = h\nu = hc/\lambda = -\Delta E$ for these transitions. Combining Equations 6.5 and 6.6, we see that

$$E_{\text{photon}} = \frac{hc}{\lambda} = -\Delta E = hcR_H\left(\frac{1}{n_f^2} - \frac{1}{n_i^2}\right) \text{(for emission)}$$

which gives us

$$\frac{1}{\lambda} = \frac{hcR_H}{hc}\left(\frac{1}{n_f^2} - \frac{1}{n_i^2}\right) = R_H\left(\frac{1}{n_f^2} - \frac{1}{n_i^2}\right), \text{ where } n_f < n_i$$

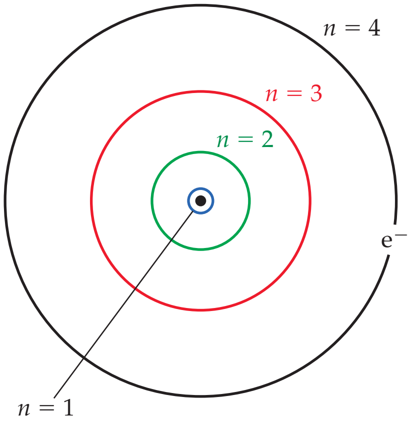
Thus, the existence of discrete spectral lines can be attributed to the quantized jumps of electrons between energy levels.

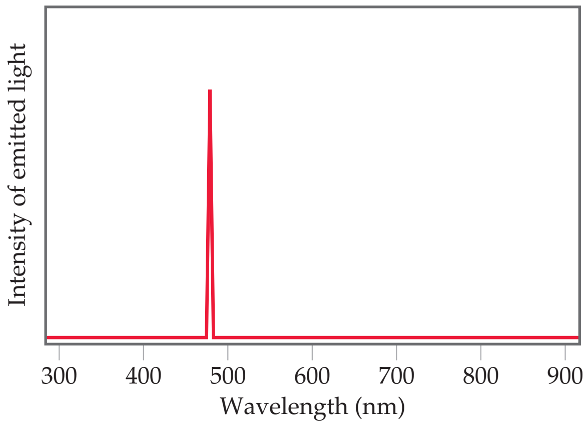
Sample Exercise 6.3

Electronic Transitions in the Hydrogen Atom

In the Bohr model of the hydrogen atom, electrons are confined to orbits with fixed radii, and those radii can be calculated. The radii of the first four orbits are 0.53, 2.12, 4.76, and 8.46 Å, respectively, as depicted below.

(**a**) If an electron makes a transition from the $n_i = 4$ level to a lower-energy level, $n_f = 3$, 2, or 1, which transition would produce a photon with the shortest wavelength? (**b**) What are the energy and wavelength of such a photon, and in which region of the electromagnetic spectrum does it lie? (**c**) The image on the right shows the output of a detector that measures the intensity of light emitted from a sample of hydrogen atoms that have been excited so that each atom begins with an electron in the $n = 4$ state. What is the final state, n_f of the transition being detected?





SOLUTION

Analyze We are asked to determine the energy and wavelength associated with various transitions involving an electron relaxing from the $n = 4$ state of the hydrogen atom to one of three lower-energy states.

Plan Given the integers representing the initial and final states of the electron, we can use Equation 6.6 to calculate the energy of the photon emitted and then use the relationships $E = h\nu$ and $c = \nu\lambda$ to convert energy to wavelength. The photon with the highest energy will have the shortest wavelength because photon energy is inversely proportional to wavelength.

Solve

(**a**) The wavelength of a photon is related to its energy through the relationship $E = h\nu = hc/\lambda$. Hence, the photon with the shortest wavelength will have the largest energy. The energy levels of the electron orbits decrease as n decreases.

The electron loses the most energy on transitioning from the $n_i = 4$ state to the $n_f = 1$ state. Consequently, the photon emitted in that transition has the highest energy and the shortest wavelength.

(**b**) We first calculate the energy of the photon using Equation 6.6 with $n_i = 4$ and $n_f = 1$:

$$\Delta E = -2.18 \times 10^{-18}\,\text{J}\left(\frac{1}{1^2} - \frac{1}{4^2}\right) = -2.04 \times 10^{-18}\,\text{J}$$

$$E_{\text{photon}} = -\Delta E = 2.04 \times 10^{-18}\,\text{J}$$

Next, we rearrange Planck's relationship to calculate the frequency of the emitted photon.

$$\nu = E/h = (2.04 \times 10^{-18}\,\cancel{\text{J}})/(6.626 \times 10^{-34}\,\cancel{\text{J}}\text{-s}) = 3.08 \times 10^{15}\,\text{s}^{-1}$$

Finally, we use the frequency to determine the wavelength.

Light with this wavelength falls in the ultraviolet region of the electromagnetic spectrum.

$$\lambda = c/\nu = (2.998 \times 10^8\,\text{m}/\cancel{\text{s}})/(3.08 \times 10^{15}\,\cancel{\text{s}^{-1}})$$
$$= 9.73 \times 10^{-8}\,\text{m} = 97.3\,\text{nm}$$

(**c**) From the graph, we estimate the wavelength of the photon to be approximately 480 nm. Starting from the wavelength, it is easiest to estimate n_f using Equation 6.4:

$$\frac{1}{\lambda} = R_H\left(\frac{1}{n_f^2} - \frac{1}{n_i^2}\right)$$

Continued

Rearranging:

$$\frac{1}{n_\mathrm{f}^2} = \frac{1}{n_\mathrm{i}^2} + \frac{1}{R_\mathrm{H}\lambda} = \frac{1}{4^2} + \frac{1}{(1.097 \times 10^7\ \cancel{\mathrm{m}^{-1}})(480 \times 10^{-9}\ \cancel{\mathrm{m}})}$$

$$\frac{1}{n_\mathrm{f}^2} = 0.25$$

So $n_\mathrm{f} = 2$, and the photons seen by the detector are those emitted when an electron transitions from the $n_\mathrm{i} = 4$ to the $n_\mathrm{f} = 2$ state.

Check Referring back to Figure 6.12, we confirm that the $n = 4$ to $n = 1$ transition should have the largest energy of the three possible transitions and thus the shortest wavelength.

▶ Practice Exercise

For each of the following transitions, give the sign of ΔE and indicate whether a photon is emitted or absorbed. (**a**) $n = 3$ to $n = 1$ (**b**) $n = 2$ to $n = 4$

Limitations of the Bohr Model

Although the Bohr model explains the line spectrum of the hydrogen atom, it cannot explain the spectra of other atoms, except in a crude way. Bohr also avoided the problem of why the negatively charged electron would not just fall into the positively charged nucleus, by simply assuming it would not happen. Furthermore, we will see that Bohr's model of an electron orbiting the nucleus at a fixed distance is not a realistic picture. As we explain in Section 6.4, the electron exhibits wave-like properties, a fact that any acceptable model of electronic structure must accommodate.

Despite its shortcomings, the Bohr model suggested an entirely different way to understand the electronic structure of atoms. Two key concepts from the Bohr model are retained in the modern picture of the hydrogen atom:

1. *Electrons exist only in certain discrete energy levels, which are described by quantum numbers.*
2. *A discrete quantity of energy is either absorbed or emitted when an electron transitions from one level to another.*

We now start to develop the successor to the Bohr model, but to do so we must first take a closer look at how the emergence of quantum theory altered our understanding of how matter behaves at the atomic and subatomic scale.

Self-Assessment Exercises

SAE 6.6 In the Bohr model of the hydrogen atom, which of the following quantities *decreases* as the value of the principal quantum number of the electron *increases*? (**a**) the distance from the electron to the nucleus (**b**) the energy of the electron (**c**) the energy required to ionize (remove an electron) the atom (**d**) the frequency of the photon emitted when the electron relaxes back to the ground state

SAE 6.7 What is the wavelength of the photon emitted when an electron in a hydrogen atom makes a transition from the $n = 3$ to the $n = 2$ state? (**a**) 821 nm (**b**) 3.03×10^{-19} m (**c**) 365 nm (**d**) 486 nm (**e**) 656 nm

6.4 | The Wave Behavior of Matter

Learning Objectives

When you finish Section 6.4, you should be able to:

- Describe the wave-like properties of matter, including the approximate scales where such effects are observable.
- Explain how the uncertainty principle limits the precision with which we can simultaneously determine the position and momentum of small particles, such as electrons.

In the early decades of the twentieth century, scientists were still mapping out the structure of the atom (Section 2.2). Once the existence of subatomic particles was accepted, scientists began to study their properties and found that they behave in surprising ways that cannot be inferred from studying larger objects. In this section we learn that, just like light, matter can behave as a particle and a wave, a key step on the path to developing a better understanding of the electronic structure of atoms.

In the years following the development of Bohr's model for the hydrogen atom, the dual nature of radiant energy became a familiar concept. Depending on the experimental circumstances, radiation appears to have either a wave-like or a particle-like (photon) character. Louis de Broglie (1892–1987), who was working on his Ph.D. thesis in physics at the Sorbonne in Paris, boldly extended this idea: If radiant energy could, under appropriate conditions, behave as though it were a stream of particles (photons), could matter, under appropriate conditions, possibly show the properties of a wave?

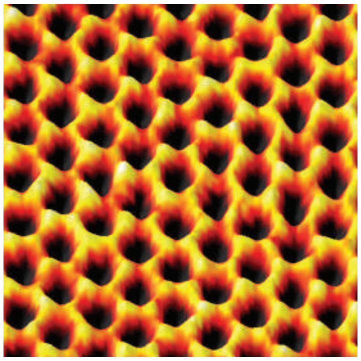
De Broglie suggested that an electron moving about the nucleus of an atom behaves like a wave and therefore has a wavelength. He proposed that the wavelength of the electron, or of any other particle, depends on its mass, m, and on its velocity, v:

$$\lambda = \frac{h}{mv} \qquad [6.8]$$

where h is the Planck constant. The quantity mv for any object is called its **momentum**. De Broglie used the term **matter waves** to describe the wave characteristics of material particles.

Because de Broglie's hypothesis is applicable to all matter, any object of mass m and velocity v would give rise to a characteristic matter wave. However, Equation 6.8 indicates that the wavelength associated with an object of ordinary size, such as a golf ball, is so tiny as to be completely unobservable. This is not so for an electron because its mass is so small, as we see in Sample Exercise 6.4.

A few years after de Broglie published his theory, the wave properties of the electron were demonstrated experimentally. When X rays pass through a crystal, an interference pattern results that is characteristic of the wave-like properties of electromagnetic radiation, a phenomenon called *X-ray diffraction*. As electrons pass through a crystal, they are similarly diffracted. Thus, a stream of moving electrons exhibits the same kinds of wave behavior as X rays and all other types of electromagnetic radiation. In the electron microscope, the wave characteristics of electrons are used to obtain images at the atomic scale. This technique has become an important tool for studying surface phenomena at very high magnifications (**Figure 6.14**). Electron microscopes can magnify objects by 3,000,000 times, far more than can be done with visible light (1000×), because the wavelength of the electrons is so much smaller than the wavelength of visible light.



▲ **Figure 6.14** **Electrons as waves.** Transmission electron micrograph of *graphene*, which has a hexagonal honeycomb arrangement of carbon atoms. Each of the bright yellow "mountains" indicates a carbon atom.

Sample Exercise 6.4

Matter Waves

What is the wavelength of an electron moving with a speed of 5.97×10^6 m/s? The mass of the electron is 9.11×10^{-31} kg.

SOLUTION

Analyze We are given the mass, m, and velocity, v, of the electron, and we must calculate its de Broglie wavelength.

Plan The wavelength of a moving particle is given by Equation 6.8, so λ is calculated by inserting the known quantities h, m, and v. In doing so, however, we must pay attention to units.

Solve
Using the value of the Planck constant, $h = 6.626 \times 10^{-34}$ J-s, we have the following:

$$\lambda = \frac{h}{mv} = \frac{(6.626 \times 10^{-34}\ \text{J-s})}{(9.11 \times 10^{-31}\ \text{kg})(5.97 \times 10^{6}\ \text{m/s})}\left(\frac{1\ \text{kg-m}^2/\text{s}^2}{1\ \text{J}}\right)$$

$$\lambda = 1.22 \times 10^{-10}\ \text{m} = 0.122\ \text{nm}$$

Comment By comparing this value with the wavelengths of electromagnetic radiation shown in Figure 6.4, we see that the wavelength of this electron is about the same as that of X rays.

▶ **Practice Exercise**
Calculate the velocity of a neutron whose de Broglie wavelength is 505 pm. The mass of a neutron is 1.675×10^{-27} kg.

The Uncertainty Principle

The discovery of the wave properties of matter raised some new and interesting questions. Consider, for example, a ball rolling down a ramp. Using the equations of classical physics, we can calculate, with great accuracy, the ball's position, direction of motion, and speed at any instant. Can we do the same for an electron, which exhibits wave properties? A wave extends in space, and its location is not precisely defined. We might therefore anticipate that it is impossible to determine exactly where an electron is located at a specific instant.

The German physicist Werner Heisenberg (1901–1976) proposed that the dual nature of matter places a fundamental limitation on how precisely we can know both the location and the momentum of an object at a given instant. The limitation becomes important only when we deal with matter at the subatomic level (that is, with masses as small as subatomic particles like the electron). Heisenberg's principle is called the **uncertainty principle**. When applied to the electrons in an atom, this principle states that it is impossible for us to know simultaneously both the exact momentum of an electron and its exact location in space.

Heisenberg mathematically related the uncertainty in position, Δx, and the uncertainty in momentum, $\Delta(mv)$, to a quantity involving the Planck constant:

$$\Delta x \cdot \Delta(mv) \geq \frac{h}{4\pi} \qquad [6.9]$$

A brief calculation illustrates the dramatic implications of the uncertainty principle. The electron has a mass of 9.11×10^{-31} kg and moves at an average speed of about 5×10^6 m/s in a hydrogen atom. Let's assume that we know the speed to an uncertainty of 1% [that is, an uncertainty of $(0.01)(5 \times 10^6 \text{ m/s}) = 5 \times 10^4 \text{ m/s}$] and that this is the only important source of uncertainty in the momentum, so that $\Delta(mv) = m\Delta v$. We can use Equation 6.9 to calculate the uncertainty in the position of the electron:

$$\Delta x \geq \frac{h}{4\pi m \Delta v} = \left(\frac{6.626 \times 10^{-34} \text{ J-s}}{4\pi(9.11 \times 10^{-31} \text{ kg})(5 \times 10^4 \text{ m/s})}\right) = 1 \times 10^{-9} \text{ m}$$

Because the diameter of a hydrogen atom is about 1×10^{-10} m, the uncertainty in the position of the electron in the atom is an order of magnitude greater than the size of the atom. Thus, we have essentially no idea where the electron is located in the atom. On the other hand, if we were to repeat the calculation with an object of ordinary mass, such as a tennis ball, the uncertainty would be so small that it would be inconsequential. In that case, m is large and Δx is out of the realm of measurement and therefore of no practical consequence.

De Broglie's hypothesis and Heisenberg's uncertainty principle set the stage for a new and more broadly applicable theory of atomic structure. In this approach, any attempt to define precisely the instantaneous location and momentum of the electron is abandoned. The wave nature of the electron is recognized, and its behavior is described in terms appropriate to waves. The result is a model that precisely describes the energy of the electron while describing its location not precisely but rather in terms of probabilities.

A CLOSER LOOK Measurement and the Uncertainty Principle

Whenever any measurement is made, some uncertainty exists. Our experience with objects of ordinary dimensions, such as balls or trains or laboratory equipment, indicates that using more precise instruments can decrease the uncertainty of a measurement. In fact, we might expect that the uncertainty in a measurement can be made infinitesimally small. However, the uncertainty principle states that there is an actual limit to the accuracy of measurements. This limit is not a restriction on how well instruments can be made; rather, it is inherent in nature. This limit has no practical consequences when dealing with ordinary-sized objects, but its implications are enormous when dealing with subatomic particles, such as electrons.

To measure an object, we must disturb it, at least a little, with our measuring device. Imagine using a flashlight to locate a large rubber ball in a dark room. You see the ball when the light from the flashlight bounces off the ball and strikes your eyes. When a beam of photons strikes an object of this size, it does not alter its position or momentum to any practical extent. Imagine, however, that you wish to locate an electron by similarly bouncing light off it into some detector. Objects can be located to an accuracy no greater than the wavelength of the radiation used. Thus, if we want an accurate position measurement for an electron, we must use a short wavelength. This means that photons of high energy must be employed. The more energy the photons have, the more momentum they impart to the electron when they strike it, which changes the electron's motion in an unpredictable way. The attempt to measure accurately the electron's position introduces considerable uncertainty in its momentum; the act of measuring the electron's position at one moment makes our knowledge of its future position inaccurate.

Suppose, then, that we use photons of longer wavelength. Because these photons have lower energy, the momentum of the electron is not so appreciably changed during measurement, but at the same time the longer wavelength limits the accuracy with which the electron's position can be determined. This is the essence of the uncertainty principle: *There is an uncertainty in simultaneously knowing both the position and the momentum of the electron that cannot be reduced beyond a certain minimum level*. The more accurately one is known, the less accurately the other is known.

Although we can never know the exact position and momentum of the electron, we can talk about the probability of its being at certain locations in space. In Section 6.5, we introduce a model of the atom that provides the probability of finding electrons of specific energies at certain positions in atoms.

Self-Assessment Exercises

SAE 6.8 The resolution of a microscope is limited to approximately one-half the wavelength of the light source. Because of this limitation, microscopes capable of obtaining atomic-scale images use electrons instead of visible light to illuminate samples. To distinguish atoms separated by a few hundred picometers, as they are in most solids, the electron wavelength should be less than or equal to approximately 200 pm. To what speed must the electrons be accelerated to attain this wavelength? (**a**) 3.6×10^{-6} m/s (**b**) 3.6×10^{6} m/s (**c**) 3.6×10^{3} m/s (**d**) 3.6×10^{9} m/s

SAE 6.9 Which of the following three statements is or are true?

(**i**) The uncertainty principle states that there is a limit to how precisely the position and momentum of a particle can simultaneously be measured.

(**ii**) The uncertainty principle helps to explain how particles can have wave-like properties.

(**iii**) The uncertainty principle is more relevant to large objects, such as a car, than to small objects, such as an electron.

(**a**) only i (**b**) only ii (**c**) both i and ii (**d**) both i and iii (**e**) All three statements are true.

6.5 Quantum Mechanics and Atomic Orbitals

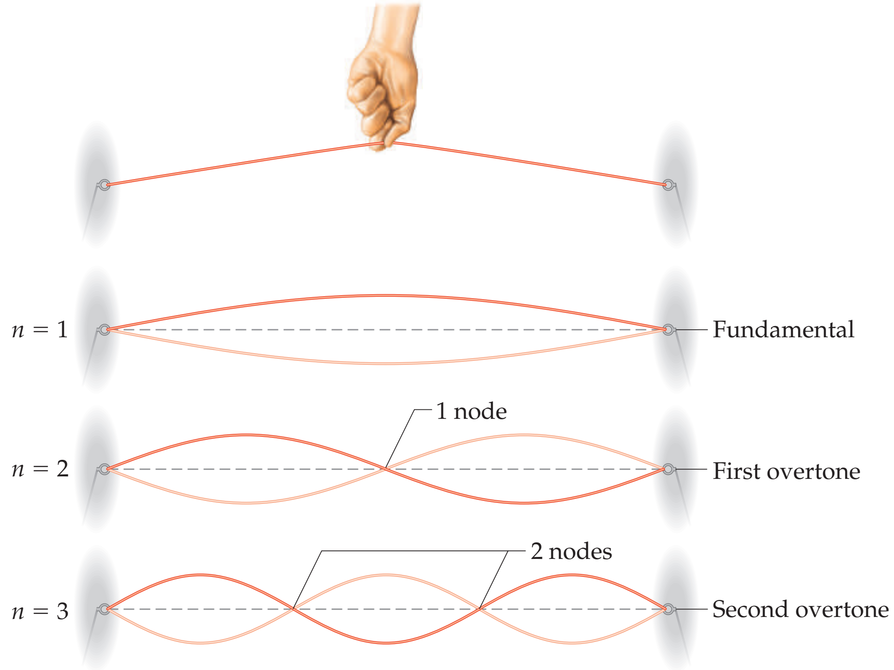
Learning Objectives

When you finish Section 6.5, you should be able to:

- Compare and contrast the atomic orbitals used in Schrödinger's model of the atom with the orbits used in Bohr's model of the atom.
- State the names and symbols of the quantum numbers and qualitatively describe how they determine the size, shape, and orientation of an atomic orbital.
- Use the rules governing the allowed combinations of quantum numbers to identify the atomic orbitals of the hydrogen atom and arrange those orbitals in order of increasing energy.

The idea that electrons have wave-like properties opens up a new way of thinking about the electronic structures of atoms. In 1926 the Austrian physicist Erwin Schrödinger (1887–1961) proposed an equation, now known as *Schrödinger's wave equation*, that incorporates both the wave-like and particle-like behaviors of the electron. His work led to a new approach to describing the behavior of electrons, an approach known as *quantum mechanics* or *wave mechanics*. The application of Schrödinger's equation requires advanced calculus that is beyond the scope of this text and is not covered here. We do qualitatively consider the results of Schrödinger's analysis, however, because they give us a powerful new way to view electronic structure.

We begin by examining the electronic structure of the simplest atom, hydrogen. Schrödinger treated the electron in a hydrogen atom like the wave on a plucked guitar string (**Figure 6.15**). Because these kinds of waves do not travel in space, they are called *standing waves*. Just as the plucked guitar string produces a standing wave that has a fundamental frequency and higher overtones (harmonics), the electron exhibits a



◀ **Figure 6.15 Standing waves in a vibrating string.**

lowest-energy standing wave and higher-energy ones. Furthermore, just as the overtones of the guitar string have *nodes*, points where the magnitude of the wave is zero, so do the waves that we use to describe the electron.

Solving Schrödinger's equation for the hydrogen atom leads to a series of mathematical functions called **wave functions** that describe the electron in the atom. These wave functions are usually represented by the symbol ψ (lowercase Greek letter *psi*). Although the wave function has no direct physical meaning, the square of the wave function, ψ^2, provides information about the electron's location when it is in an allowed energy state.

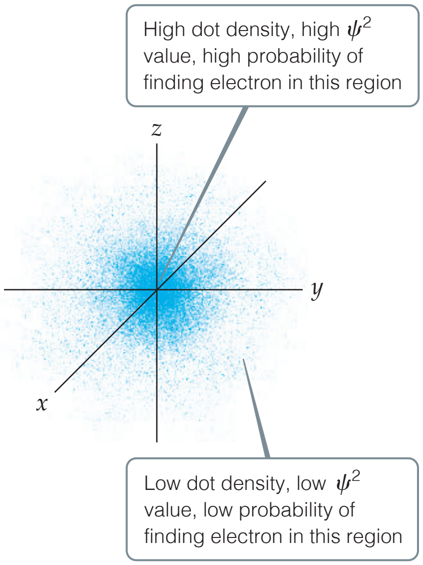
For the hydrogen atom, the allowed energies are the same as those predicted by the Bohr model. However, the Bohr model assumes that the electron is in a circular orbit of some particular radius about the nucleus. In the quantum-mechanical model, the electron's location cannot be described so simply.

According to the uncertainty principle, if we know the momentum of the electron with a high degree of accuracy, then our simultaneous knowledge of its location is very uncertain. Thus, we cannot hope to specify the exact location of an individual electron with respect to the nucleus, as was assumed in the Bohr model. Rather, we must be content with a kind of statistical knowledge. We therefore speak of the *probability* that the electron will be in a certain region of space at a given instant. As it turns out, the square of the wave function, ψ^2, at a given point in space represents the probability that the electron will be found at that location. For this reason, ψ^2 is called either the **probability density** or the **electron density**.

One way of representing the probability of finding the electron in various regions of an atom is shown in **Figure 6.16**, where the density of the dots represents the probability of finding the electron. The regions with a high density of dots correspond to relatively large values for ψ^2 and are therefore regions where there is a high probability of finding the electron. Based on this representation, we often describe atoms as consisting of a nucleus surrounded by an electron cloud.

Go Figure

Where in the figure is the region of highest electron density?



High dot density, high ψ^2 value, high probability of finding electron in this region

Low dot density, low ψ^2 value, low probability of finding electron in this region

▲ **Figure 6.16 Electron-density distribution.** This rendering represents the probability, ψ^2, of finding the electron in a hydrogen atom in its ground state. The origin of the coordinate system is at the nucleus.

Orbitals and Quantum Numbers

The solution to Schrödinger's equation for the hydrogen atom yields a set of wave functions called **orbitals**. Each orbital has a characteristic shape and energy. For example, the lowest-energy orbital in the hydrogen atom has the spherical shape illustrated in Figure 6.16 and an energy of -2.18×10^{-18} J. Note that an *orbital* (quantum-mechanical model, which describes electrons in terms of probabilities, visualized as "electron clouds") is not the same as an *orbit* (the Bohr model, which visualizes the electron moving in a physical orbit, like a planet around a star). The quantum-mechanical model does not refer to orbits because the motion of the electron in an atom cannot be precisely determined (Heisenberg's uncertainty principle).

The Bohr model introduced a single quantum number, n, to describe an orbit. The quantum-mechanical model uses three quantum numbers, n, l, and m_l, which result naturally from the mathematics used to describe an orbital.

1. The principal quantum number, n, can have positive integral values 1, 2, 3, ... As n increases, the orbital becomes larger, and the electron spends more time farther from the nucleus. An increase in n also means that the electron has a higher energy and is therefore less tightly bound to the nucleus. For the hydrogen atom, $E_n = -(2.18 \times 10^{-18}\text{ J})(1/n^2)$, as in the Bohr model.
2. The second quantum number—the **angular momentum quantum number**, l—can have integral values from 0 to $(n-1)$ for each value of n. This quantum number is related to the fact that, even in the quantum-mechanical model, the electron can be viewed as having certain values of *angular momentum*—the momentum of a particle moving in a curved orbit. The amount of angular momentum is limited by the energy of the electron, which explains why the allowed values of l are limited by the value of n. Not all orbitals have the same shape, and this quantum number defines the shape of the orbital. The value of l for a

particular orbital is generally designated by the letters *s*, *p*, *d*, and *f*,* corresponding to *l* values of 0, 1, 2, and 3:

Value of *l*	0	1	2	3
Letter used	*s*	*p*	*d*	*f*

3. The **magnetic quantum number**, m_l, can have integral values between $-l$ and l, including zero. When $l \neq 0$, the shape of the orbital is nonspherical and the value of m_l defines the orientation of the orbital in space, as we discuss in Section 6.6.

A CLOSER LOOK Schrödinger's Cat and Quantum Computing

The revolutions in scientific thinking caused by the theory of relativity and quantum theory changed far more than just science; it also caused deep changes in how we understand the world around us. Before relativity and quantum theory, the prevailing physical theories were inherently *deterministic*: Once the specific conditions of an object were given (position, velocity, forces acting on the object), we could determine exactly the position and motion of the object at any time in the future. These theories, from Newton's laws to Maxwell's theory of electromagnetism, successfully described physical phenomena such as motion of the planets, the trajectories of projectiles, and the diffraction of light.

In this chapter we have touched on two tenets of quantum theory that lead to a nondeterministic description of matter. First, we have seen that the descriptions of light and matter have become less distinct—light has particle-like properties and matter has wave-like properties. The description of matter that results—in which we can talk only about the probability of an electron being at a certain place as opposed to knowing exactly where it is—was very bothersome to many. Einstein, for example, famously said that "God doesn't play dice with the world"* about this probabilistic description. Heisenberg's uncertainty principle, which asserts that we can't know the position and momentum of a particle exactly, also raised many philosophical questions—so many, in fact, that Heisenberg wrote a book entitled *Physics and Philosophy* in 1958.

One of the common methods scientists used to test these new theories was through so-called thought experiments. Thought experiments are hypothetical scenarios that can lead to paradoxes within a given theory. One of the most famous thought experiments put forward in the early days of the quantum theory was formulated by Schrödinger and is now known as "Schrödinger's cat" (**Figure 6.17**). This experiment called into question whether a system could have multiple acceptable wave functions prior to observation of the system. In other words, if we don't actually observe a system, can we know anything about the state it is in? In this paradox, a hypothetical cat is placed in a sealed box with an apparatus that will randomly trigger a lethal dose of poison to the cat (as morbid as that sounds). According to some interpretations of quantum theory, until the box is opened and the cat is observed, the cat must be considered simultaneously alive and dead.

Schrödinger posed this paradox to point out the weaknesses in some interpretations of quantum results, but the paradox has led instead to a continuing and lively debate about the fate and meaning of Schrödinger's cat. In 2012, the Nobel Prize in Physics was awarded to Serge Haroche of France and David Wineland of the United States for their ingenious methods for observing the quantum states of photons or particles without having the act of observation destroy the states. In so doing, they observed what is generally called the "cat state" of the system, in which the photon or particle exists simultaneously in two different quantum states.

As counterintuitive as this concept is at first blush, many believe it can be harnessed to create so-called quantum computers. In a conventional computer, each bit of information has a specific value, either 0 or 1, and these bits can only be processed one after the other. In a quantum computer, information is stored in a quantum bit, or *qubit*, which is a superposition of two different states. Just as Schrödinger's cat can be simultaneously dead and alive, a qubit can be a combination of 0 and 1 at the same time. Provided you can keep different qubits in coherence with each other, the computing power of a quantum computer increases rapidly as the number of qubits increases, much more so than you can achieve by increasing the number of binary bits in a conventional computer. Scientists have done calculations with 20 coherent qubits, and even with this modest number of qubits, they can create over one million superimposed states. Unfortunately, these "cat states" are very sensitive to interactions with their environment, including thermal fluctuations, which can collapse the superposition down to the simple 0 and 1 of a conventional bit. The main challenge for harnessing the power of quantum computing is to find ways to make this superposition of states more stable.

Related Exercise: 6.96

	2	$4d$	$2, 1, 0, -1, -2$	5	
	3	$4f$	$3, 2, 1, 0, -1, -2, -3$	7	16

Because the value of n can be any positive integer, there are an infinite number of orbitals for the hydrogen atom. At any given instant, however, the electron in a hydrogen atom is described by only one of these orbitals—we say that the electron *occupies* a certain orbital. The remaining orbitals are *unoccupied* for that particular state of the hydrogen atom. We focus mainly on orbitals that have small values of n.

The collection of orbitals with the same value of n is called an **electron shell**. For example, all orbitals that have $n = 3$ are said to be in the third shell. The set of orbitals that have the same n and l values is called a **subshell**. Each subshell is designated by a number (the value of n) and a letter (s, p, d, or f, corresponding to the value of l). For example, the orbitals that have $n = 3$ and $l = 2$ are called $3d$ orbitals and are said to be in the $3d$ subshell.

Table 6.2 summarizes the possible values of l and m_l for values of n through $n = 4$. The restrictions on possible values give rise to the following very important observations:

1. *The shell with principal quantum number* n *consists of exactly* n *subshells*. Each subshell corresponds to a different allowed value of l from 0 to $(n - 1)$ Thus, the first shell $(n = 1)$ consists of only one subshell, the $1s$ $(l = 0)$; the second shell $(n = 2)$ consists of two subshells, the $2s$ $(l = 0)$ and $2p$ $(l = 1)$; the third shell consists of three subshells, $3s$, $3p$, and $3d$; and so forth.
2. *Each subshell consists of a specific number of orbitals*. Each orbital corresponds to a different allowed value of m_l. For a given value of l, there are $(2l + 1)$ allowed values of m_l, ranging from $-l$ to $+l$. Thus, each s $(l = 0)$ subshell consists of one orbital; each p $(l = 1)$ subshell consists of three orbitals; each d $(l = 2)$ subshell consists of five orbitals, and so forth.
3. *The total number of orbitals in a shell is* n^2, *where* n *is the principal quantum number of the shell*. The resulting number of orbitals for the shells—1, 4, 9, 16—is related to a pattern seen in the periodic table: We see that the number of elements in the rows of the periodic table—2, 8, 18, and 32—equals twice these numbers. We discuss this relationship further in Section 6.9.

Figure 6.18 shows the relative energies of the hydrogen atom orbitals through $n = 3$. Each box represents an orbital, and orbitals of the same subshell, such as the three $2p$ orbitals, are grouped together. When the electron occupies the lowest-energy orbital ($1s$), the hydrogen atom is said to be in its *ground state*. When the electron occupies any other orbital, the atom is in an *excited state*. (The electron can be excited to a higher-energy orbital by absorption of a photon of appropriate energy.) At ordinary temperatures, essentially all hydrogen atoms are in the ground state.

Go Figure

Sample Exercise 6.5

Subshells of the Hydrogen Atom

(**a**) Without referring to Table 6.2, predict the number of subshells in the fourth shell—that is, for $n = 4$. (**b**) Give the label for each of these subshells. (**c**) How many orbitals are in each of these subshells?

SOLUTION

Analyze and Plan We are given the value of the principal quantum number, n. We need to determine the allowed values of l and m_l for this given value of n and then count the number of orbitals in each subshell.

Solve There are four subshells in the fourth shell, corresponding to the four possible values of l (0, 1, 2, and 3).

These subshells are labeled 4*s*, 4*p*, 4*d*, and 4*f*. The number given in the designation of a subshell is the principal quantum number, n; the letter designates the value of the angular momentum quantum number, l: the label is *s* for $l = 0$; *p* for $l = 1$; *d* for $l = 2$; and *f* for $l = 3$.

There is one 4*s* orbital (when $l = 0$, the only possible value of m_l is 0). There are three 4*p* orbitals (when $l = 1$, there are three possible values of m_l: 1, 0, −1). There are five 4*d* orbitals (when $l = 2$, there are five allowed values of m_l: 2, 1, 0, −1, −2). There are seven 4*f* orbitals (when $l = 3$, there are seven permitted values of m_l: 3, 2, 1, 0, −1, −2, −3).

Practice Exercise

What is the designation for the subshell with $n = 5$ and $l = 1$? (**b**) How many orbitals are in this subshell? (**c**) Indicate the values of m_l for each of these orbitals.

Self-Assessment Exercises

6.6 | Representations of Orbitals

Thus far we have emphasized the energies of orbitals, but the wave function also provides information about an electron's probable location in space. In this section we examine the ways in which we can picture orbitals, because their shapes help us visualize how the electron density is distributed around the nucleus. We use the shapes of orbitals extensively in subsequent chapters of the text, especially when we talk about the formation of chemical bonds.

Learning Objectives

When you finish Section 6.6, you should be able to:

- Interpret the radial probability function of an atomic orbital.
- Compare and contrast the three-dimensional shapes of *s*, *p*, and *d* orbitals.

The s Orbitals

We have already seen one representation of the lowest-energy orbital of the hydrogen atom, the 1*s* (Figure 6.16). The electron density for the 1*s* orbital is *spherically symmetric*. In other words, the electron density at a given distance from the nucleus is the same regardless of the direction in which we proceed from the nucleus. All of the other *s* orbitals (2*s*, 3*s*, 4*s*, and so forth) are also spherically symmetric and centered on the nucleus.

The l quantum number for the *s* orbitals is 0, so the m_l quantum number must also be 0. Thus, for each value of n, there is only one *s* orbital. So how do *s* orbitals differ as the value of n changes? For example, how does the electron-density distribution of the hydrogen atom change when the electron is excited from the 1*s* orbital to the 2*s* orbital?

According to quantum mechanics, we must describe the position of the electron in the hydrogen atom in terms of probabilities rather than exact locations. The information about the probability is contained in the wave functions, ψ, obtained from Schrödinger's equation. Because *s* orbitals are spherically symmetric, the value of ψ for an electron in an *s* orbital depends only on its distance from the nucleus, *r*. The wave functions for the 1*s*, 2*s*, and 3*s* orbitals are shown at the top of **Figure 6.19**. All three wave functions drop off exponentially upon moving away from the nucleus, but for the 1*s* orbital the value of the wave function remains a positive number regardless of the distance from the nucleus. In contrast, the value of the 2*s* wave function crosses over from positive to negative at a distance approximately 1 Å from the nucleus, while the 3*s* wave function changes sign twice. Analogous to our descriptions of the standing waves of the guitar string (Figure 6.15), we refer to the points where the wave function changes sign as **nodes**.

The square of the wave function, ψ^2 (the probability density), gives the probability that the electron is located at any *point* in space. The probability density plots for the 1*s*, 2*s*, and 3*s* orbitals as a function of the distance *r* from the nucleus are shown immediately below the wave function plots in Figure 6.19. Notice that both $\psi(r)$ and $[\psi(r)]^2$ attain their largest values at the nucleus. This is true of all *s* orbitals, but not of the *p*, *d*, and *f* orbitals we discuss later.

To determine the *total* probability of finding the electron at a given distance from the nucleus, we need to "add up" the probability densities $[\psi(r)]^2$ over all points that are a distance *r* from the nucleus. This gives a function called the **radial probability function**. To add up all of the individual probability densities requires calculus and is therefore beyond the scope of this text, but the result of that calculation tells us that the radial probability function is equal to the probability density, $[\psi(r)]^2$, multiplied by the surface area of a sphere, $4\pi r^2$:

$$\text{Radial probability function (at a distance } r \text{ from the nucleus)} = 4\pi r^2[\psi(r)]^2$$

The radial probability functions for the 1*s*, 2*s*, and 3*s* orbitals are shown in the bottom set of panels of Figure 6.19. The fact that $4\pi r^2$ increases rapidly as we move away from the nucleus makes the radial probability function and the probability density look distinctly different from each other. For example, the plot of $[\psi(r)]^2$ for the 3*s* orbital in Figure 6.19 generally gets smaller the farther we move away from the nucleus. But when we multiply by $4\pi r^2$, we see peaks that get larger and larger (up to a certain point) as *r* increases. The cutaway images shown at the bottom of Figure 6.19 give a three-dimensional picture of the radial probability function. The values of *r* where the radial probability density goes to 0, represented by white shells in these cutaway images, are the nodes where the wave function changes sign.

For the 1*s* orbital, we see that the radial probability function rises rapidly as we move away from the nucleus, maximizing at about 0.5 Å. Thus, when the electron occupies the 1*s* orbital, it is *most likely* to be found this distance from the nucleus.* Notice that we use the probabilistic description, consistent with the uncertainty principle. We can also see for the 1*s* orbital that the probability of finding the electron at a distance greater than about 3 Å from the nucleus is very small.

Turning next to the radial probability functions for the 2*s* and 3*s* orbitals, we see three trends as the value of the principal quantum number *n* changes:

1. For an *ns* orbital, the number of peaks is equal to *n*, with the outermost peak being larger than inner ones.
2. For an *ns* orbital, the number of nodes is equal to $n - 1$. Because these types of nodes are located at specific distances from the nucleus, we refer to them as **radial nodes**.
3. As *n* increases, the electron density becomes more spread out—that is, there is a greater probability of finding the electron further from the nucleus.

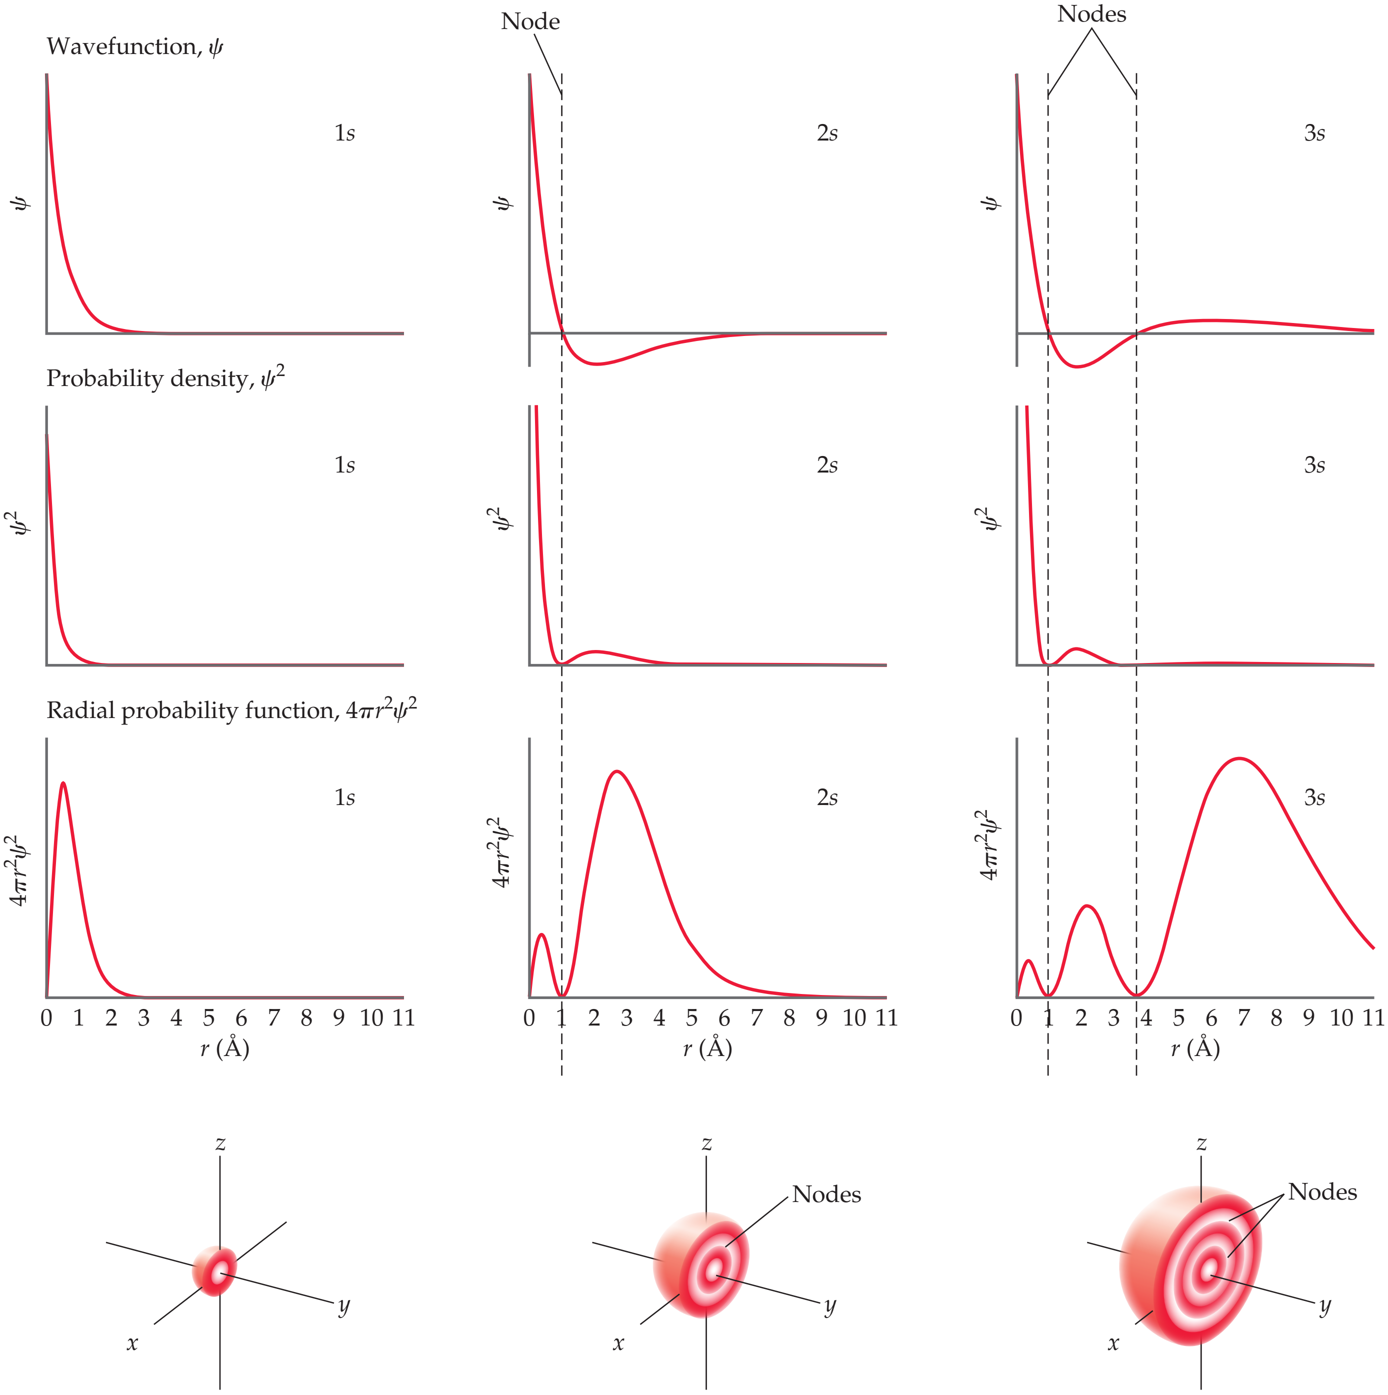
---

* In the quantum-mechanical model, the most probable distance at which to find the electron in the 1*s* orbital is actually 0.529 Å, the same as the radius of the orbit predicted by Bohr for $n = 1$. The distance 0.529 Å is often called the *Bohr radius*.

Go Figure

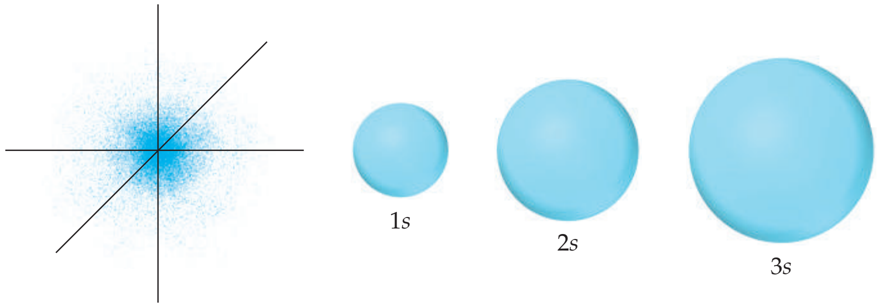
How many maxima would you expect to find in the radial probability function for the 4*s* orbital of the hydrogen atom? How many nodes would you expect in this function?

▼ **Figure 6.19** **The wave function $\psi(r)$, probability density $[\psi(r)]^2$, and radial probability function $4\pi r^2[\psi(r)]^2$ for the 1*s*, 2*s*, and 3*s* orbitals of hydrogen.** As *n* increases, the number of nodes (marked with dashed lines) increases and the most probable distance to find the electron (the highest peak in the radial probability function) moves farther from the nucleus. The cutaway views at the bottom provide a three-dimensional representation of the radial probability function.



One widely used method of representing orbital *shape* is to draw a boundary surface that encloses some substantial portion, say 90%, of the electron density for the orbital. This type of drawing is called a *contour representation*, and the contour representations for the *s* orbitals are spheres (**Figure 6.20**). All the orbitals have the same shape, but they differ in size, becoming larger as *n* increases, reflecting the fact that the electron density becomes more spread out as *n* increases. Although the details of how electron density

▶ Figure 6.20 Comparison of the 1*s*, 2*s*, and 3*s* orbitals. (**a**) Electron-density distribution of a 1*s* orbital. (**b**) Contour representations of the 1*s*, 2*s*, and 3*s* orbitals. Each sphere is centered on the atom's nucleus and encloses the volume in which there is a 90% probability of finding the electron.



(a) An electron-density model

(b) Contour models

varies within a given contour representation are lost in these representations, this is not a serious disadvantage. For qualitative discussions, the most important features of orbitals are shape and relative size, which are adequately displayed by contour representations.

The *p* Orbitals

The orbitals for which $l = 1$ are the *p* orbitals. Each *p* subshell has three orbitals, corresponding to the three allowed values of $m_l = -1$, 0, and 1. The distribution of electron density for one of the 2*p* orbitals is shown in **Figure 6.21(a)**. The electron density is not distributed spherically as in an *s* orbital. Instead, the density is concentrated in two regions on either side of the nucleus, separated by a node at the nucleus. We say that this dumbbell-shaped orbital has two *lobes*; for this particular 2*p* orbital, the two lobes are centered along the $+z$ and $-z$ axes of a coordinate system. Recall that we are making no statement about how the electron is moving within the orbital. Figure 6.21(a) portrays only the *averaged* distribution of the electron density in a 2*p* orbital. Notice that the wave function ψ and probability density $[\psi]^2$ go to zero at all points in the *xy* plane. When the wave function has a node that extends over an entire plane, we can refer to this type of node as an **angular node** or **nodal plane**.* For a given orbital, the number of nodal planes is equal to the value of angular momentum quantum number *l*.

Beginning with the $n = 2$ shell, each shell has three *p* orbitals (Table 6.2), one for each allowed value of m_l. Thus, there are three 2*p* orbitals, three 3*p* orbitals, and so forth. Each set of *p* orbitals has the dumbbell shapes shown in Figure 6.21(a). For each value of *n,* the three *p* orbitals have the same size and shape but differ from one another in spatial orientation. We usually represent *p* orbitals by drawing the shape and orientation of their wave functions, as shown in the contour representations in Figure 6.21(b). These orbitals can be labeled as p_x, p_y, and p_z, where the letter subscript indicates the Cartesian axis along which the orbital is oriented. Just as the $2p_z$ orbital has the *xy* plane as its nodal plane, the $2p_x$ and $2p_y$ orbitals have the *yz* and *xz* planes as nodal planes, respectively. Thus, we see that two orbitals with the same value of *n* and *l*, but different values of m_l, differ from each other in the way they are oriented in space.† Like *s* orbitals, *p* orbitals increase in size as we move from 2*p* to 3*p* to 4*p*, and so forth.

The *d* and *f* Orbitals

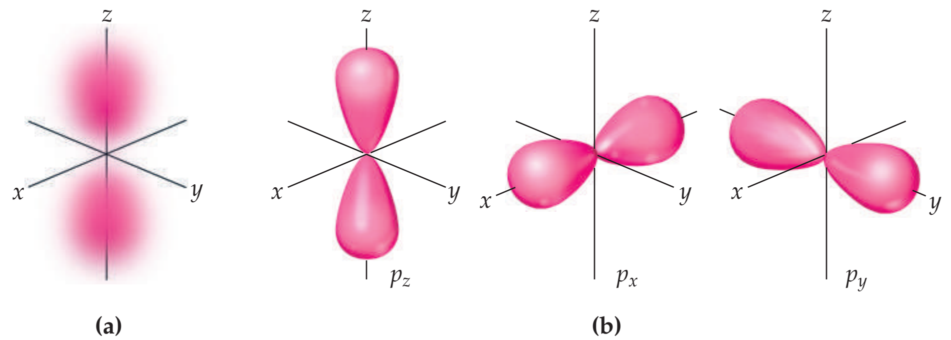
When *n* is 3 or greater, we encounter the *d* orbitals (for which $l = 2$). There are five 3*d* orbitals, five 4*d* orbitals, and so forth, because in each shell there are five possible values for the m_l quantum number: -2, -1, 0, 1, and 2. The different *d* orbitals in a given shell have different shapes and orientations in space, as shown in **Figure 6.22**. Four of the *d*-orbital

---

* For some *d* and *f* orbitals, such as the d_{z^2} orbital, the surface over which the angular node extends is a cone rather than a plane. For this reason, the term *nodal surface* is sometimes used instead of nodal plane.

† We cannot make a simple correspondence between the subscripts (x, y, and z) and the allowed m_l values (1, 0, and -1).

Go Figure For which of the orbitals below is the yz plane a nodal plane?



▲ **Figure 6.21** **The *p* orbitals.** (**a**) Electron-density distribution of a 2p orbital. (**b**) Contour representations of the three p orbitals. The subscript on the orbital label indicates the axis along which the orbital lies.

contour representations have a "four-leaf clover" shape, with four lobes, and each lies primarily in a plane. The d_{xy}, d_{xz}, and d_{yz} orbitals lie in the xy, xz, and yz planes, respectively, with the lobes oriented *between* the axes. The lobes of the $d_{x^2-y^2}$ orbital also lie in the xy plane, but the lobes lie *along* the x and y axes. The d_{z^2} orbital looks very different from the other four: It has two lobes along the z axis and a "doughnut" in the xy plane. Even though the d_{z^2} orbital looks different from the other d orbitals, it has the same energy as the other four d orbitals. The contour representations in Figure 6.22 are used for all d orbitals, regardless of the principal quantum number, but just as is the case for the s and p orbitals the size of the orbital increases as n increases.

When n is 4 or greater, there are seven equivalent f orbitals (for which $l = 3$). The shapes of the f orbitals are even more complicated than those of the d orbitals and are not presented here. As we discuss in Section 6.7, however, you must be aware of f orbitals when we consider the electronic structure of atoms in the lower part of the periodic table.

In many instances later in the text, you will find that knowing the number and shapes of atomic orbitals will help you understand chemistry at the molecular level. You will therefore find it useful to memorize the shapes of the s, p, and d orbitals shown in Figures 6.20, 6.21, and 6.22.

Self-Assessment Exercises

SAE 6.14 Which of the following statements is or are true for the wave functions describing the s orbitals as the value of the principal quantum number, n, increases?

(i) The number of radial nodes increases.

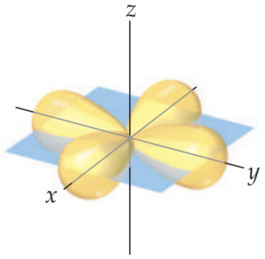
(ii) The number of times the probability density $[\psi(r)]^2$ changes sign increases.

(iii) The distance between the nucleus and the largest peak in the radial distribution function increases

(a) only i **(b)** only iii **(c)** both i and ii **(d)** both i and iii **(e)** all three are true.

SAE 6.15 Which of the following statements is *true*? **(a)** The number of radial nodes in an orbital can be determined from inspection of its contour representation, but not the number of nodal planes. **(b)** The number of nodal planes in an orbital can be determined from inspection of its contour representation, but not the number of radial nodes. **(c)** The number of radial nodes and the number of nodal planes in an orbital can be determined by inspection of its contour representation. **(d)** No information about nodes can be ascertained by inspecting the contour representation of an orbital.

SAE 6.16 Given the contour representation for an atomic orbital shown here, which of the following statements is *false*? **(a)** This orbital has two nodal planes. **(b)** For this orbital, the angular momentum quantum number l must be 2. **(c)** For this orbital, the principal quantum number n must be 3. **(d)** This is a d orbital.



6.7 | Many-Electron Atoms

Learning Objectives

When you finish Section 6.7, you should be able to:

- Compare the energy levels of atomic orbitals in a many-electron atom to those in a hydrogen atom.
- Describe the concept of electron spin.
- Describe the Pauli exclusion principle and explain how it limits the number of electrons each atomic orbital can hold.

We have seen that quantum mechanics provides an elegant description of the hydrogen atom. If we want to describe atoms with more than one electron (a *many-electron* atom) the situation becomes more complicated due to interactions between the electrons. Fortunately, the basic characteristics of the wave functions are retained in many-electron atoms. In this section we consider the relative energies of the orbitals in many-electron atoms as well as how the electrons populate the available orbitals.

Orbitals and Their Energies

We can describe the electronic structure of a many-electron atom by using the orbitals we described for the hydrogen atom in Table 6.2. Thus, the orbitals of a many-electron atom also have designations such as $1s$ and $2p_x$, and they have the same general shapes as the corresponding hydrogen orbitals.

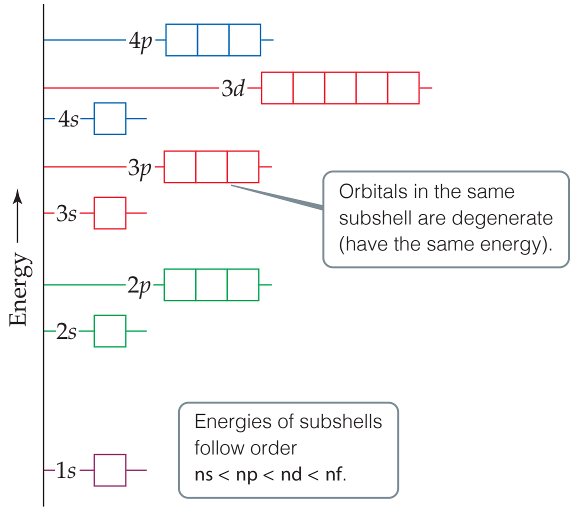
Although the shapes of the orbitals of a many-electron atom are the same as those for hydrogen, the presence of more than one electron alters the energies of the orbitals. In hydrogen, the energy of an orbital depends only on its principal quantum number, n (Figure 6.18). For instance, in a hydrogen atom, the $3s$, $3p$, and $3d$ subshells all have the same energy. In a many-electron atom, however, the energies of the various subshells in a given shell are *different* because of electron–electron repulsions. To explain why this happens, we must consider the forces between the electrons and how these forces are affected by the shapes of the orbitals.

The details of this analysis are given in Chapter 7, but the important idea is this: *In a many-electron atom, for a given value of* n, *the energy of an orbital increases as the value of* l *increases*, as illustrated in **Figure 6.23**. For example, the $n = 3$ orbitals increase in energy in the order $3s < 3p < 3d$. Nevertheless, all orbitals of a given subshell (such as the five $3d$ orbitals) retain the same energy in a many-electron atom, just as they do in the hydrogen atom. Orbitals with the same energy are said to be **degenerate**.

Figure 6.23 is a *qualitative* energy-level diagram; the exact energies of the orbitals and their spacings differ from one atom to another.

Go Figure

Not all orbitals in the $n = 4$ shell are shown in this figure. Which subshells are missing?



Orbitals in the same subshell are degenerate (have the same energy).

Energies of subshells follow order ns < np < nd < nf.

▲ **Figure 6.23 General energy ordering of orbitals for a many-electron atom.**

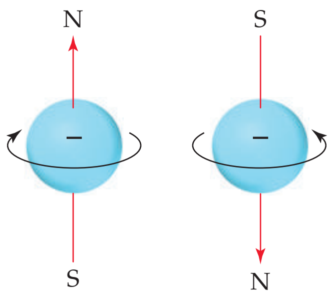
Electron Spin and the Pauli Exclusion Principle

In the hydrogen atom there is only a single electron. In the ground state it occupies the $1s$ orbital, while in an excited state it can, in principle, occupy any orbital. How do the electrons of a many-electron atom populate the available orbitals? To answer this question, we must consider an additional property of the electron.

When scientists studied the line spectra of many-electron atoms in great detail, they noticed a very puzzling feature: Lines that were originally thought to be single were actually closely spaced pairs. This meant, in essence, that there were twice as many energy levels as there were "supposed" to be. In 1925, the Dutch physicists George Uhlenbeck (1900–1988) and Samuel Goudsmit (1902–1978) proposed a solution to this dilemma. They postulated that electrons have an intrinsic property, called **electron spin**, that causes each electron to behave as if it were a tiny sphere spinning on its own axis.

By now, it may not surprise you to learn that electron spin is quantized. This observation led to the assignment of a new quantum number for the electron, in addition to *n, l,* and m_l, which we have already discussed. This new quantum number, the **spin magnetic quantum number**, is denoted m_s (the subscript *s* stands for *spin*). Two possible values are allowed for m_s, $+\frac{1}{2}$ or $-\frac{1}{2}$, or which were first interpreted as indicating the two opposite directions in which the electron can spin. The link between magnetism and spin comes from the fact that a spinning charge produces a magnetic field. The two opposite directions of spin therefore produce oppositely directed magnetic fields (**Figure 6.24**).* These two opposite magnetic fields lead to the splitting of spectral lines into closely spaced pairs.

The concept of electron spin is crucial for understanding the electronic structures of atoms. In 1925, the Austrian-born physicist Wolfgang Pauli (1900–1958) discovered the principle that governs the arrangement of electrons in many-electron atoms. The **Pauli exclusion principle** states that *no two electrons in an atom can have the same set of four quantum numbers* n, l, m_l *and* m_s. For a given orbital, the values of *n*, *l*, and m_l are fixed. Thus, if we want to put more than one electron in an orbital *and* satisfy the Pauli exclusion principle, our only choice is to assign different m_s values to the electrons. Because there are only two such values, we conclude that *an orbital can hold a maximum of two electrons and they must have opposite spins*. This restriction allows us to index the electrons in an atom, giving their quantum numbers and thereby defining the region in space where each electron is most likely to be found. It also provides the key to understanding the remarkable structure of the periodic table of the elements.



▲ **Figure 6.24** **Electron spin.** The electron behaves as if it were spinning about an axis, thereby generating a magnetic field whose direction depends on the direction of spin. The two directions for the magnetic field correspond to the two possible values for the spin quantum number, m_s. The magnetic fields that emanate from materials, like iron, arise because there are more electrons with one spin direction than the other.

Self-Assessment Exercises

SAE 6.17 If two electrons in a multielectron atom are in degenerate orbitals, which quantum number(s) must be the same? **(a)** *n* **(b)** *l* **(c)** m_l **(d)** *n* and *l* **(e)** *n*, *l*, and m_l

SAE 6.18 Which of the following statements is or are true?

(i) The value of the spin magnetic quantum number m_s depends on the value of the magnetic quantum number m_l.

(ii) There are two possible values of the spin magnetic quantum number m_s.

(**a**) only i (**b**) only ii (**c**) Both i and ii are true. (**d**) Neither i nor ii is true.

SAE 6.19 An oxygen atom has eight electrons. In the ground state, which orbitals will be populated with electrons? (**a**) 1*s* (**b**) 1*s* and 2*s* (**c**) 1*s*, 2*s*, and 2*p* (**d**) 1*s*, 2*s*, 2*p*, 3*s*, and 3*p*

6.8 Electron Configurations

Now that we know the relative energies of orbitals and the Pauli exclusion principle, we are in a position to understand the arrangements of electrons in atoms. The way electrons are distributed among the various orbitals of an atom is called the **electron configuration** of the atom. Electron configurations are central to many chemical and physical properties of the elements. The tendency for atoms to form bonds with other atoms or to participate in oxidation–reduction reactions is determined in part by the electron configuration, as are the magnetic and optical properties of many substances.

The most stable electron configuration—the ground state—is that in which the electrons are in the lowest possible energy states. If there were no restrictions on the possible values for the quantum numbers of the electrons, all the electrons would crowd into the

Learning Objectives

When you finish Section 6.8, you should be able to:

- Determine the expected ground-state electron configuration of any atom and use various representations to express it.
- Use Hund's rule and an orbital diagram to determine the number of unpaired electrons for any atom or ion.

---

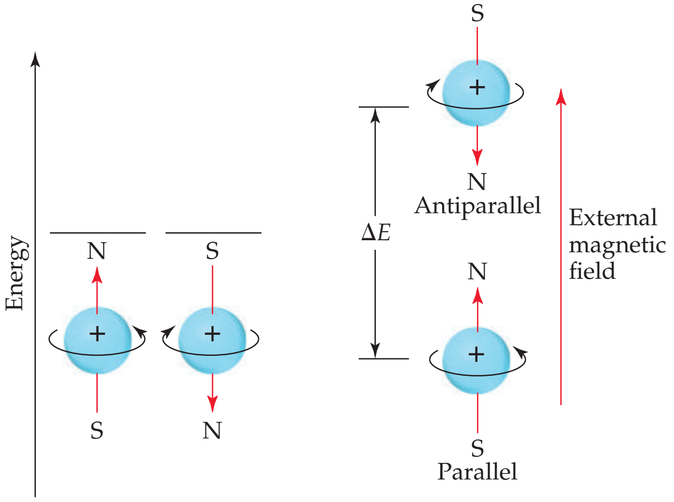
* As we discussed previously, the electron has both particle-like and wave-like properties. Thus, the picture of an electron as a spinning charged sphere is, strictly speaking, just a useful pictorial representation that helps us understand the two directions of magnetic field that an electron can possess.

CHEMISTRY AND LIFE Nuclear Spin and Magnetic Resonance Imaging

A major challenge facing medical diagnosis is seeing inside the human body. For many years this was accomplished primarily by X-ray technology. X rays, however, do not give well-resolved images of overlapping physiological structures, and sometimes they fail to discern diseased or injured tissue. Moreover, because X rays are high-energy radiation, they potentially can cause physiological harm, even in low doses. An imaging technique developed in the 1980s called *magnetic resonance imaging* (*MRI*) does not have these disadvantages.

The foundation of MRI is a phenomenon called *nuclear magnetic resonance (NMR)*, which was discovered in the mid-1940s. Today NMR has become one of the most important spectroscopic methods used in chemistry. NMR is based on the observation that, like electrons, the nuclei of many elements possess an intrinsic spin. Like electron spin, nuclear spin is quantized. For example, the nucleus of ^{1}H has two possible magnetic nuclear spin quantum numbers, $+\frac{1}{2}$ and $-\frac{1}{2}$.

A spinning hydrogen nucleus acts like a tiny magnet. In the absence of external effects, the two spin states have the same energy. However, when the nuclei are placed in an external magnetic field, they can align either parallel or opposed (antiparallel) to the field, depending on their spin. The parallel alignment is lower in energy than the antiparallel one by a certain amount, ΔE (**Figure 6.25**). If the nuclei are irradiated with photons having energy equal to ΔE, the spin of the nuclei can be "flipped"—that is, excited from the parallel to the antiparallel alignment. Detection of the flipping of nuclei between the two spin states leads to an NMR spectrum. The radiation used in an NMR experiment is in the radiofrequency range, typically 100 to 900 MHz, which is far less energetic per photon than X rays.



(a) No external magnetic field

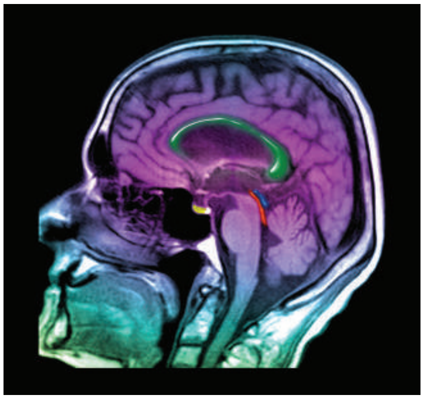
(b) External magnetic field applied

▲ **Figure 6.25 Nuclear spin.** Like electron spin, nuclear spin generates a small magnetic field and its values are quantized. (**a**) In the absence of an external magnetic field, the two spin states of a hydrogen nucleus have the same energy. (**b**) When an external magnetic field is applied, the spin state in which the spin direction is parallel to the direction of the external field is lower in energy than the spin state in which the spin direction is antiparallel to the field direction. The energy difference, ΔE, between the two states is in the radio frequency region of the electromagnetic spectrum.

Because hydrogen is a major constituent of aqueous body fluids and fatty tissue, the hydrogen nucleus is the most convenient one for study by MRI. In MRI a person's body is placed in a strong magnetic field. By irradiating the body with pulses of radiofrequency radiation and using sophisticated detection techniques, medical technicians can image tissue at specific depths in the body, giving pictures with spectacular detail (**Figure 6.26**). The ability to sample at different depths allows the technicians to construct a three-dimensional picture of the body.

MRI has had such a profound influence on the modern practice of medicine that Paul Lauterbur, a chemist, and Peter Mansfield, a physicist, were awarded the 2003 Nobel Prize in Physiology or Medicine for their discoveries concerning MRI. The major drawback of this technique is expense: The cost of a new standard MRI instrument for clinical applications can easily run in excess of a million dollars. Improvements in MRI technology now allow for millimeter resolution of biological features small enough to detect tumors before they become metastatic.

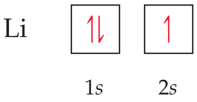
Related Exercise: 6.98



▲ **Figure 6.26 MRI image.** This image of a human head, obtained using magnetic resonance imaging, shows a normal brain, airways, and facial tissues.

1*s* orbital because it is the lowest in energy (Figure 6.23). According to the Pauli exclusion principle, however, there can be at most two electrons in any single orbital. Thus, *the orbitals are filled in order of increasing energy, with no more than two electrons per orbital.* The lithium atom, for example, has three electrons. (Recall that the number of electrons in a neutral atom equals its atomic number.) The 1*s* orbital can accommodate two of the electrons. The third one goes into the next lowest-energy orbital, the 2*s*.

We can represent any electron configuration by writing the symbol for the occupied subshell and adding a superscript to indicate the number of electrons in that subshell. For example, for lithium we write $1s^{2}2s^{1}$ (read "1*s* two, 2*s* one"). We can also show the arrangement of the electrons as



In this representation, which we call an **orbital diagram**, each orbital is denoted by a box and each electron by a half arrow. A half arrow pointing up (↿) represents an electron with a positive spin magnetic quantum number ($m_s = +\frac{1}{2}$), whereas a half arrow pointing down (⇂) represents an electron with a negative spin magnetic quantum number ($m_s = -\frac{1}{2}$). This pictorial representation of electron spin, which corresponds to the directions of the magnetic fields in Figure 6.24, is quite convenient. Chemists refer to the two possible spin states as "spin-up" and "spin-down" corresponding to the directions of the half arrows.

Electrons having opposite spins are said to be *paired* when they are in the same orbital (↿⇂). An *unpaired electron* is one not accompanied by a partner of opposite spin. In the lithium atom the two electrons in the 1*s* orbital are paired, whereas the electron in the 2*s* orbital is unpaired.

Hund's Rule

How do the electron configurations of the elements change as we move from element to element across the periodic table?

TABLE 6.3 Electron Configurations of Several Lighter Elements

Element	Total Electrons	Orbital Diagram						Electron Configuration
		1*s*	2*s*	2*p*			3*s*	
Li	3	↿⇂	↿					$1s^22s^1$
Be	4	↿⇂	↿⇂					$1s^22s^2$
B	5	↿⇂	↿⇂	↿				$1s^22s^22p^1$
C	6	↿⇂	↿⇂	↿	↿			$1s^22s^22p^2$
N	7	↿⇂	↿⇂	↿	↿	↿		$1s^22s^22p^3$
Ne	10	↿⇂	↿⇂	↿⇂	↿⇂	↿⇂		$1s^22s^22p^6$
Na	11	↿⇂	↿⇂	↿⇂	↿⇂	↿⇂	↿	$1s^22s^22p^63s^1$

Hydrogen Hydrogen has one electron, which occupies the 1*s* orbital in its ground state:

H ↿ : $1s^1$

1*s*

The choice of a spin-up electron here is arbitrary; we could equally well show the ground state with one spin-down electron. It is customary, however, to show unpaired electrons with their spins up.

Helium The next element, helium, has two electrons. Because two electrons with opposite spins can occupy the same orbital, both of helium's electrons are in the 1*s* orbital:

He ↿⇂ : $1s^2$

1*s*

The two electrons present in helium complete the filling of the first shell. This arrangement represents a very stable configuration, which is consistent with the chemical inertness of helium.

Lithium The electron configurations of lithium and several elements that follow it in the periodic table are shown in **Table 6.3**. For the third electron of lithium, the change in the principal quantum number from $n = 1$ for the first two electrons to $n = 2$ for the third electron represents a large jump in energy and a corresponding jump in the average distance of the electron from the nucleus. In other words, it represents the start of a new shell occupied with electrons. As you can see by examining the periodic table, lithium starts a new row of the table. It is the first member of the alkali metals (group 1A).

Beryllium and Boron The element that follows lithium is beryllium; its electron configuration is $1s^22s^2$ (Table 6.3). Boron, atomic number 5, has the electron configuration $1s^22s^22p^1$. The fifth electron must be placed in a $2p$ orbital because the $2s$ orbital is filled. Because all three of the $2p$ orbitals are of equal energy, it does not matter which $2p$ orbital we place this fifth electron in.

Carbon With the next element, carbon, we encounter a new situation. We know that the sixth electron must go into a $2p$ orbital, but does it go into the $2p$ orbital that already has one electron or into one of the other two $2p$ orbitals?

> ***Hund's rule*** *states that when filling degenerate orbitals, the lowest energy is attained when the number of electrons having the same spin is maximized.*

This means that electrons occupy orbitals singly to the maximum extent possible and that these single electrons in a given subshell all have the same spin magnetic quantum number. Electrons arranged in this way are said to have *parallel spins*. For a carbon atom to achieve its lowest energy, therefore, the two $2p$ electrons must have the same spin. For this to happen, the electrons must be in different $2p$ orbitals, as shown in Table 6.3. Thus, a carbon atom in its ground state has two unpaired electrons.

Nitrogen, Oxygen, Fluorine Similarly, for nitrogen in its ground state, Hund's rule requires that the three $2p$ electrons singly occupy each of the three $2p$ orbitals. This is the only way that all three electrons can have the same spin. For oxygen and fluorine, we place four and five electrons, respectively, in the $2p$ orbitals. To achieve this, we pair up electrons in the $2p$ orbitals, as we demonstrate in Sample Exercise 6.6.

The rationale behind Hund's rule is based in large part on the fact that electrons repel one another. By occupying different orbitals, the electrons remain as far as possible from one another, thus minimizing electron–electron repulsions.

Sample Exercise 6.6

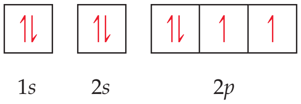
Orbital Diagrams and Electron Configurations

Draw the orbital diagram for the electron configuration of oxygen, atomic number 8. How many unpaired electrons does an oxygen atom possess?

SOLUTION

Analyze and Plan Because oxygen has an atomic number of 8, each oxygen atom has eight electrons. Figure 6.23 shows the ordering of orbitals. The electrons (represented as half arrows) are placed in the orbitals (represented as boxes) beginning with the lowest-energy orbital, the $1s$. Each orbital can hold a maximum of two electrons (the Pauli exclusion principle). Because the $2p$ orbitals are degenerate, we place one electron in each of these orbitals (spin-up) before pairing any electrons (Hund's rule).

Solve Two electrons each go into the $1s$ and $2s$ orbitals with their spins paired. This leaves four electrons for the three degenerate $2p$ orbitals. Following Hund's rule, we put one electron into each $2p$ orbital until all three orbitals have one electron each. The fourth electron is then paired up with one of the three electrons already in a $2p$ orbital, so that the orbital diagram is



The corresponding electron configuration is written $1s^22s^22p^4$. The atom has two unpaired electrons.

Practice Exercise

(**a**) Write the electron configuration for silicon, element 14, in its ground state. (**b**) How many unpaired electrons does a ground-state silicon atom possess?

Condensed Electron Configurations

The filling of the $2p$ subshell is complete at neon (Table 6.3), which has a stable configuration with eight electrons (an *octet*) in the outermost occupied shell. The next element, sodium, atomic number 11, marks the beginning of a new row of the periodic table. Sodium has a single $3s$ electron beyond the stable configuration of neon. We can therefore abbreviate the electron configuration of sodium as

$$\text{Na:}\quad [\text{Ne}]3s^1$$

The symbol [Ne] represents the electron configuration of the ten electrons of neon, $1s^22s^22p^6$. Writing the electron configuration as $[\text{Ne}]3s^1$ focuses attention on the outermost electron of the atom, which is the one largely responsible for how sodium behaves chemically.

We can generalize what we have just done for the electron configuration of sodium. In writing the *condensed electron configuration* of an element, the electron configuration of the nearest noble-gas element of lower atomic number is represented by its chemical symbol in brackets. For lithium, for example, we can write

$$\text{Li:}\quad [\text{He}]2s^1$$

We refer to the electrons represented by the bracketed symbol as the *noble-gas core* of the atom. These inner-shell electrons are often referred to as the **core electrons**. The electrons given after the noble-gas core are called the *outer-shell electrons*. The outer-shell electrons include the electrons involved in chemical bonding, which are called the **valence electrons**. For the elements with atomic number of 30 or less, all of the outer-shell electrons are valence electrons. By comparing the condensed electron configurations of lithium and sodium, we can appreciate why these two elements are so similar chemically. They have the same type of electron configuration in the outermost occupied shell. Indeed, all the members of the alkali metal group (1A) have a single *s* valence electron beyond a noble-gas configuration.

Transition Metals

The noble-gas element argon ($1s^22s^22p^63s^23p^6$) marks the end of the row started by sodium. The element following argon in the periodic table is potassium (K), atomic number 19. In all its chemical properties, potassium is clearly a member of the alkali metal group. The experimental facts about the properties of potassium leave no doubt that the outermost electron of this element occupies an *s* orbital. But this means that the electron with the highest energy has *not* gone into a 3*d* orbital, which we might expect it to do. Because the 4*s* orbital is lower in energy than the 3*d* orbital (Figure 6.23), the condensed electron configuration of potassium is

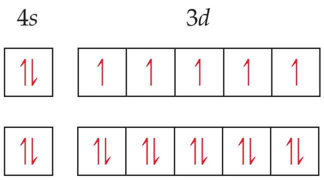
$$\text{K:}\quad [\text{Ar}]4s^1$$

Following the complete filling of the 4*s* orbital (this occurs in the calcium atom), the next set of orbitals to be filled is the 3*d*. (You will find it helpful as we go along to refer often to the periodic table on the front-inside cover.) Beginning with scandium and extending through zinc, electrons are added to the five 3*d* orbitals until they are completely filled. Thus, the fourth row of the periodic table is ten elements wider than the two previous rows. These ten elements are known as either **transition elements** or **transition metals**. Note the position of these elements in the periodic table.

In writing the electron configurations of the transition elements, we fill orbitals in accordance with Hund's rule; we add them to the 3*d* orbitals singly until all five orbitals have one electron each and then place additional electrons in the 3*d* orbitals with spin pairing until the shell is completely filled. The condensed electron configurations and the corresponding orbital diagram representations of two transition elements are as follows:

Mn: $[\text{Ar}]4s^23d^5$ or [Ar]

Zn: $[\text{Ar}]4s^23d^{10}$ or [Ar]



Once all the 3*d* orbitals have been filled with two electrons each, the 4*p* orbitals begin to be occupied until the completed octet of outer electrons ($4s^24p^6$) is reached with krypton (Kr), atomic number 36, another of the noble gases. Rubidium (Rb) marks the beginning of the fifth row. Refer again to the periodic table on the front-inside cover. Notice that this row is in every respect like the preceding one, except that the value for *n* is greater by 1.

The Lanthanides and Actinides

The sixth row of the periodic table begins with Cs and Ba, which have [Xe]$6s^1$ and [Xe]$6s^2$ configurations, respectively. Notice, however, that the periodic table then has a break, with elements 57–70 placed below the main portion of the table. This break point is where we begin to encounter a new set of orbitals, the 4*f* orbitals.

There are seven degenerate 4*f* orbitals, corresponding to the seven allowed values of m_l, ranging from 3 to -3. Thus, it takes 14 electrons to fill the 4*f* orbitals completely. The 14 elements corresponding to the filling of the 4*f* orbitals are known as either the **lanthanide elements** or the **rare earth elements**. These elements are set below the other elements to avoid making the periodic table unduly wide. The properties of the lanthanide elements are all quite similar, and these elements occur together in nature. For many years it was virtually impossible to separate them from one another.

Because the energies of the 4*f* and 5*d* orbitals are very close to each other, the electron configurations of some of the lanthanides involve 5*d* electrons. For example, the elements lanthanum (La), cerium (Ce), and praseodymium (Pr) have the following electron configurations:

[Xe]$6s^25d^1$	[Xe]$6s^25d^14f^1$	[Xe]$6s^24f^3$
Lanthanum	Cerium	Praseodymium

Because La has a single 5*d* electron, it is sometimes placed below yttrium (Y) as the first member of the third series of transition elements; Ce is then placed as the first member of the lanthanides. Based on its chemical properties, however, La can be considered the first element in the lanthanide series. Arranged this way, there are fewer apparent exceptions to the regular filling of the 4*f* orbitals among the subsequent members of the series.

After the lanthanide series, the third transition element series is completed by the filling of the 5*d* orbitals, followed by the filling of the 6*p* orbitals. This brings us to radon (Rn), the heaviest naturally occurring noble-gas element.

The final row of the periodic table begins by filling the 7*s* orbitals. The **actinide elements**, of which uranium (U, element 92) and plutonium (Pu, element 94) are the best known, are then built up by completing the 5*f* orbitals. All of the actinide elements are radioactive, and most of them are *not* found in nature.

Self-Assessment Exercises

SAE 6.20 What is the full ground-state electron configuration for Ti?

(a) $1s^22s^22p^63s^23p^64s^23d^2$
(b) $1s^22s^22p^63s^23p^64s^24p^2$
(c) $1s^22s^22p^63s^23p^63d^4$
(d) $1s^22s^22p^63s^23p^64s^4$

SAE 6.21 A ground-state Sn atom has a condensed electron configuration of ________ and possesses ________ unpaired electrons.

(a) [Kr]$5s^25p^2$, two **(b)** [Kr]$5s^24d^{10}5p^2$, two **(c)** [Kr]$5s^25p^2$, zero **(d)** [Kr]$5s^24d^{10}5p^2$, zero **(e)** [Kr]$5s^25d^{10}5p^2$, two

6.9 | Electron Configurations and the Periodic Table

Learning Objectives

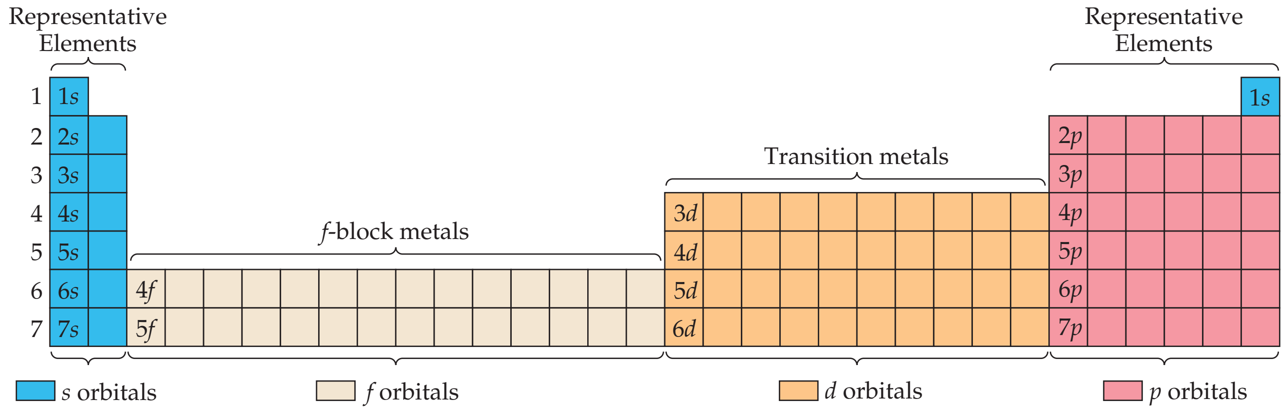
When you finish Section 6.9, you should be able to:

- Explain how the organization of the periodic table arises from the electron configurations of the elements.
- Identify and name the various blocks of elements that make up the periodic table.

Now that we've learned how to assign electron configurations, the structure of the periodic table should start to make more sense to you. In this section we examine the connection between the periodic table and the electron configurations of the elements. We also discuss how to use the periodic table as a guide to remember the relative energy levels of the different atomic orbitals in multi-electron atoms.

We just saw that the electron configurations of the elements correspond to their locations in the periodic table. Thus, elements in the same column of the table have related outer-shell (valence) electron configurations. As **Table 6.4** shows, for example, all 2A elements have an ns^2 outer configuration, and all 3A elements have an ns^2np^1 outer configuration, with the value of *n* increasing as we move down each column.

In Table 6.2 we saw that the total number of orbitals in each shell equals n^2:1, 4, 9, or 16. Because we can place two electrons in each orbital, each shell accommodates up to $2n^2$ electrons: 2, 8, 18, or 32. The overall structure of the periodic table reflects these electron numbers: Each row of the table has 2, 8, 18, or 32 elements in it. As shown in **Figure 6.27**, the periodic table can be further divided into four blocks based on the filling order of orbitals. On the left are *two* blue columns of elements. These elements, known as the alkali



▲ **Figure 6.27 Regions of the periodic table.** The order in which electrons are added to orbitals is read left to right beginning in the top-left corner.

metals (group 1A) and alkaline earth metals (group 2A), are those in which the valence *s* orbitals are being filled. These two columns make up the *s* block of the periodic table.

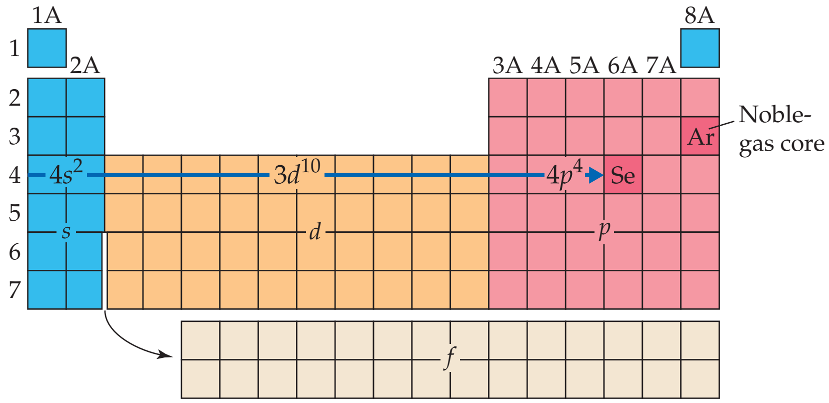
On the right is a block of *six* pink columns that comprises the *p* block, where the valence *p* orbitals are being filled. The *s* block and the *p* block elements together are the **representative elements**, sometimes called the **main-group elements**. The orange block in Figure 6.27 has *ten* columns containing the **transition metals**. These are the elements in which the valence *d* orbitals are being filled and make up the *d* block. The elements in the two tan rows containing *14* columns are the ones in which the valence *f* orbitals are being filled and make up the *f* block. Consequently, these elements are often referred to as the ***f*-block metals**. In most instances, the *f* block is positioned below the periodic table to save space.

The number of columns in each block corresponds to the maximum number of electrons that can occupy each kind of subshell. Recall that 2, 6, 10, and 14 are the numbers of electrons that can fill the *s*, *p*, *d*, and *f* subshells, respectively. Thus, the *s* block has 2 columns, the *p* block has 6, the *d* block has 10, and the *f* block has 14. Recall also that 1*s* is the first *s* subshell, 2*p* is the first *p* subshell, 3*d* is the first *d* subshell, and 4*f* is the first *f* subshell, as Figure 6.27 shows. Using these facts, you can write the electron configuration of an element based merely on its position in the periodic table. Remember: *The periodic table is your best guide to the order in which orbitals are filled.*

Let's use the periodic table to write the electron configuration of selenium (Se, element 34). We first locate Se in the table and then move backward from it through the table, from element 34 to 33 to 32, and so forth, until we come to the noble gas that precedes Se. In this case, the noble gas is argon, Ar, element 18. Thus, the noble-gas core for Se is [Ar]. Our next step is to write symbols for the outer electrons. We do this by moving across period 4 from K, the element following Ar, to Se:

TABLE 6.4 Electron Configurations of Group 2A and 3A Elements

Group 2A	
Be	$[\mathrm{He}]2s^2$
Mg	$[\mathrm{Ne}]3s^2$
Ca	$[\mathrm{Ar}]4s^2$
Sr	$[\mathrm{Kr}]5s^2$
Ba	$[\mathrm{Xe}]6s^2$
Ra	$[\mathrm{Rn}]7s^2$
Group 3A	
B	$[\mathrm{He}]2s^2 2p^1$
Al	$[\mathrm{Ne}]3s^2 3p^1$
Ga	$[\mathrm{Ar}]3d^{10}4s^2 4p^1$
In	$[\mathrm{Kr}]4d^{10}5s^2 5p^1$
Tl	$[\mathrm{Xe}]4f^{14}5d^{10}6s^2 6p^1$



Because K is in the fourth period and the *s* block, we begin with the 4*s* electrons, meaning our first two outer electrons are written $4s^2$. We then move into the *d* block, which begins with the 3*d* electrons. The principal quantum number in the *d* block is always one less than that of the preceding elements in the *s* block, as seen in Figure 6.27. Traversing the *d* block adds ten electrons, $3d^{10}$. Finally, we move into the *p* block, whose principal quantum number is always the same as that of the *s* block. Counting the squares as we move across the *p* block to Se indicates that we need four electrons, $4p^4$. The electron configuration for Se is therefore $[\mathrm{Ar}]4s^23d^{10}4p^4$. This configuration can also be written with the subshells arranged in order of increasing principal quantum number: $[\mathrm{Ar}]3d^{10}4s^24p^4$.

As a check, we add the number of electrons in the [Ar] core, 18, to the number of electrons we added to the 4*s*, 3*d*, and 4*p* subshells. This sum should equal the atomic number of Se, 34, which it does: $18 + 2 + 10 + 4 = 34$.

Sample Exercise 6.7

Electron Configurations from the Periodic Table

(**a**) Based on its position in the periodic table, write the condensed electron configuration for bismuth, element 83. (**b**) How many unpaired electrons does a bismuth atom have?

SOLUTION

(**a**) Our first step is to write the noble-gas core. We do this by locating bismuth, element 83, in the periodic table. We then move backward to the nearest noble gas, which is Xe, element 54. Thus, the noble-gas core is [Xe].

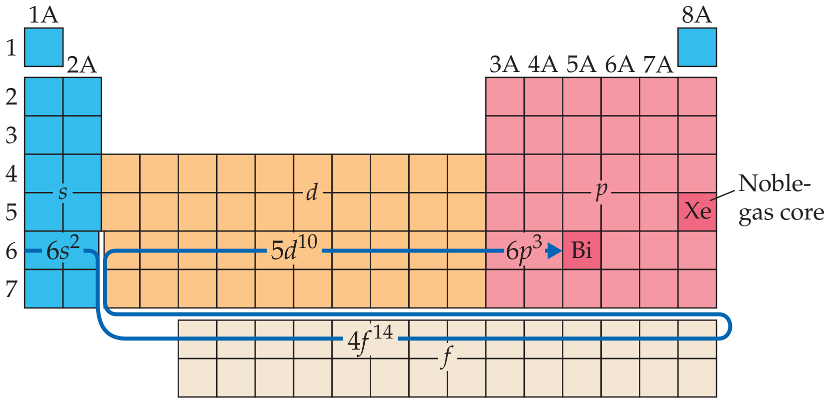
Next, we trace the path in order of increasing atomic numbers from Xe to Bi. Moving from Xe to Cs, element 55, we find ourselves in period 6 of the *s* block. Knowing the block and the period identifies the subshell in which we begin placing outer electrons, 6*s*. As we move through the *s* block, we add two electrons: $6s^2$.

As we move beyond the *s* block, from element 56 to element 57, the curved arrow below the periodic table reminds us that we are entering the *f* block. The first row of the *f* block corresponds to the 4*f* subshell. As we move across this block, we add 14 electrons: $4f^{14}$.

With element 71, we move into the third row of the *d* block. Because the first row of the *d* block is 3*d,* the second row is 4*d* and the third row is 5*d*. Thus, as we move through the ten elements of the *d* block, from element 71 to element 80, we fill the 5*d* subshell with ten electrons: $5d^{10}$.

Moving from element 80 to element 81 puts us into the *p* block in the 6*p* subshell. (Remember that the principal quantum number in the *p* block is the same as that in the *s* block.) Moving across to Bi requires three electrons: $6p^3$. Putting the parts together, we obtain the condensed electron configuration: $[\mathrm{Xe}]6s^24f^{14}5d^{10}6p^3$. This configuration can also be written with the subshells arranged in order of increasing principal quantum number: $[\mathrm{Xe}]4f^{14}5d^{10}6s^26p^3$.

Finally, we check our result to see if the number of electrons equals the atomic number of Bi, 83: Because Xe has 54 electrons (its atomic number), we have $54 + 2 + 14 + 10 + 3 = 83$. (If we had come up with 14 electrons too few, it would be a clue that we had forgotten the *f* block.)



(**b**) We see from the condensed electron configuration that the only partially occupied subshell is 6*p*. The orbital diagram representation for this subshell is

In accordance with Hund's rule, the three 6*p* electrons occupy the three 6*p* orbitals singly, with their spins parallel. Thus, there are three unpaired electrons in the bismuth atom.

Practice Exercise

Use the periodic table to write the condensed electron configuration for (**a**) Co (element 27), (**b**) In (element 49).

Figure 6.28 gives, for all the elements, the ground-state electron configurations for the outer-shell electrons. You can use this figure to check your answers as you practice writing electron configurations. We have written these configurations with orbitals listed in order of increasing principal quantum number. As we saw in Sample Exercise 6.7, the orbitals can also be listed in order of filling, as they would be read off of the periodic table.

Go Figure

A friend tells you that her favorite element has an electron configuration of [noble gas]$6s^24f^{14}5d^6$. Which element is it?

☐ Metals ▨ Metalloids 🟩 Nonmetals

▲ **Figure 6.28** **Outer-shell electron configurations of the elements.**

Figure 6.28 allows us to reexamine the concept of *valence electrons*. Notice, for example, that as we proceed from Cl ([Ne]$3s^23p^5$) to Br ([Ar]$3d^{10}4s^24p^5$), we add a complete subshell of $3d$ electrons to the electrons beyond the [Ar] core. Although the $3d$ electrons are outer-shell electrons, they are not involved in chemical bonding and are therefore not considered valence electrons. Thus, we consider only the $4s$ and $4p$ electrons of Br to be valence electrons. Similarly, if we compare the electron configurations of Ag (element 47) and Au (element 79), we see that Au has a completely full $4f^{14}$ subshell beyond its noble-gas core, but those $4f$ electrons are not involved in bonding. In general, *for representative elements we do not consider the electrons in completely filled* d *or* f *subshells to be valence electrons,* and *for transition elements we do not consider the electrons in a completely filled* f *subshell to be valence electrons.*

Anomalous Electron Configurations

The electron configurations of certain elements appear to violate the rules we have just discussed. For example, Figure 6.28 shows that the electron configuration of chromium (element 24) is [Ar]$3d^54s^1$ rather than the [Ar]$3d^44s^2$ configuration we might expect. Similarly, the configuration of copper (element 29) is [Ar]$3d^{10}4s^1$ instead of [Ar]$3d^94s^2$.

This anomalous behavior is largely a consequence of the closeness of the 3*d* and 4*s* orbital energies. It frequently occurs when there are enough electrons to form precisely half-filled sets of degenerate orbitals (as in chromium) or a completely filled *d* subshell (as in copper). There are a few similar cases among the heavier transition metals (those with partially filled 4*d* or 5*d* orbitals) and among the *f*-block metals. Although these minor departures from the expected are interesting, they are not of great chemical significance.

Self-Assessment Exercises

SAE 6.22 In which column of the periodic table would you find an atom with a valence electron configuration of ns^2np^3? (**a**) group 2A (**b**) group 3A (**c**) group 5A (**d**) group 7A

SAE 6.23 In which part of the periodic table would you expect to find the element(s) with the largest number of unpaired electrons? (**a**) the representative elements (**b**) the transition elements (**c**) the rare earth elements

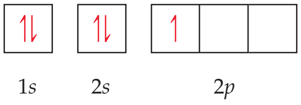
Putting Concepts Together

Boron, atomic number 5, occurs naturally as two isotopes, ^{10}B and ^{11}B, with natural abundances of 19.9% and 80.1%, respectively. (**a**) In what ways do the two isotopes differ from each other? Does the electronic configuration of ^{10}B differ from that of ^{11}B? (**b**) Draw the orbital diagram for an atom of ^{11}B. Which electrons are the valence electrons? (**c**) Indicate three ways in which the 1*s* electrons in boron differ from its 2*s* electrons. (**d**) Elemental boron reacts with fluorine to form BF_3, a gas. Write a balanced chemical equation for the reaction of solid boron with fluorine gas. (**e**) ΔH_f° for $BF_3(g)$ is -1135.6 kJ/mol. Calculate the standard enthalpy change in the reaction of boron with fluorine. (**f**) Will the mass percentage of F be the same in $^{10}BF_3$ and $^{11}BF_3$? If not, why is that the case?

SOLUTION

(**a**) The two isotopes of boron differ in the number of neutrons in the nucleus. (Sections 2.3 and 2.4) Each of the isotopes contains five protons, but ^{10}B contains five neutrons, whereas ^{11}B contains six neutrons. The two isotopes of boron have identical electron configurations, $1s^22s^22p^1$, because each has five electrons.

(**b**) The complete orbital diagram is



The valence electrons are the ones in the outermost occupied shell, the $2s^2$ and $2p^1$ electrons. The $1s^2$ electrons constitute the core electrons, which we represent as [He] when we write the condensed electron configuration, $[\text{He}]2s^22p^1$.

(**c**) The 1*s* and 2*s* orbitals are both spherical, but they differ in three important respects: First, the 1*s* orbital is lower in energy than the 2*s* orbital. Second, the average distance of the 2*s* electrons from the nucleus is greater than that of the 1*s* electrons, so the 1*s* orbital is smaller than the 2*s*. Third, the 2*s* orbital has one node, whereas the 1*s* orbital has no nodes (Figure 6.19).

(**d**) The balanced chemical equation is

$$2\,B(s) + 3\,F_2(g) \longrightarrow 2\,BF_3(g)$$

(**e**) $\Delta H^\circ = 2(-1135.6) - [0 + 0] = -2271.2$ kJ. The reaction is strongly exothermic.

(**f**) As we saw in Equation 3.13 (Section 3.3), the mass percentage of an element in a substance depends on the formula weight of the substance. The formula weights of $^{10}BF_3$ and $^{11}BF_3$ are different because of the difference in the masses of the two isotopes (the isotope masses of ^{10}B and ^{11}B are 10.01294 and 11.00931 amu, respectively). The denominators in Equation 3.13 would therefore be different for the two isotopes, whereas the numerators would remain the same.

Chapter Summary and Key Terms

WAVELENGTHS AND FREQUENCIES OF LIGHT (INTRODUCTION AND SECTION 6.1) The **electronic structure** of an atom describes the energies and arrangement of electrons around the atom. Much of what is known about the electronic structure of atoms was obtained by observing the interaction of light with matter.

Visible light and other forms of **electromagnetic radiation** (also known as radiant energy) move through a vacuum at the speed of light, $c = 2.998 \times 10^8$ m/s. Electromagnetic radiation has both electric and magnetic components that vary periodically in wavelike fashion. The wave characteristics of radiant energy allow it to be described in terms of **wavelength**, λ, and **frequency**, ν, which are interrelated: $\lambda\nu = c$.

QUANTIZED ENERGY AND PHOTONS (SECTION 6.2) To explain blackbody radiation, Planck proposed that the minimum amount of radiant energy that an object can gain or lose is related to the frequency of the radiation: $E = h\nu$. This smallest quantity is called a **quantum** of energy. The constant *h* is called the **Planck constant**: $h = 6.626 \times 10^{-34}$ J-s.

In the quantum theory, energy is quantized, meaning that it can have only certain allowed values. Einstein used quantum theory to explain the **photoelectric effect**, the emission of electrons from metal surfaces when exposed to light. He proposed that light behaves as if it consists of quantized energy packets called **photons**. Each photon carries energy, $E = h\nu$.

BOHR MODEL OF THE HYDROGEN ATOM (SECTION 6.3) Dispersion of radiation into its component wavelengths produces a **spectrum**. If the spectrum contains all wavelengths, it is called a **continuous spectrum**; if it contains only certain specific wavelengths, the spectrum is called a **line spectrum**. The radiation emitted by excited hydrogen atoms forms a line spectrum.

Bohr proposed a model of the hydrogen atom that explains its line spectrum. In this model, the energy of the electron in the hydrogen atom depends on the value of a quantum number, n, called the **principal quantum number**. The value of n must be a positive integer (1, 2, 3, . . .), and each value of n corresponds to a different specific energy, E_n. The energy of the atom increases as n increases. The lowest energy is achieved for $n = 1$, and this is called the **ground state** of the hydrogen atom. Other values of n correspond to **excited states**. Light is emitted when the electron drops from a higher-energy state to a lower-energy state; light is absorbed to excite the electron from a lower-energy state to a higher-energy state. The frequency of light emitted or absorbed is such that $h\nu$ equals the difference in energy between two allowed states.

WAVE BEHAVIOR OF MATTER (SECTION 6.4) De Broglie proposed that matter, such as electrons, should exhibit wave-like properties. This hypothesis of **matter waves** was proved experimentally by observing the diffraction of electrons. An object has a characteristic wavelength that depends on its **momentum**, mv: $\lambda = h/mv$.

Discovery of the wave properties of the electron led to Heisenberg's **uncertainty principle**, which states that there is an inherent limit to the accuracy with which the position and momentum of a particle can be measured simultaneously.

QUANTUM MECHANICS AND ORBITALS (SECTION 6.5) In the quantum-mechanical model of the hydrogen atom, the behavior of the electron is described by mathematical functions called **wave functions**, denoted with the Greek letter ψ. Each allowed wave function has a precisely known energy, but the location of the electron cannot be determined exactly; rather, the probability of it being at a particular point in space is given by the **probability density**, ψ^2. The **electron-density** distribution is a map of the probability of finding the electron at all points in space.

The allowed wave functions of the hydrogen atom are called **orbitals**. An orbital is uniquely identified by the values of three quantum numbers. The *principal quantum number*, n, is indicated by the integers 1, 2, 3, ... This quantum number relates most directly to the size and energy of the orbital. The **angular momentum quantum number**, l, is indicated by the letters s, p, d, f, and so on, corresponding to the values of 0, 1, 2, 3, . . . , respectively. The l quantum number defines the shape of the orbital. For a given value of n, l can have integer values ranging from 0 to $(n - 1)$. The **magnetic quantum number**, m_l, relates to the orientation of the orbital in space. For a given value of l, m_l can have integral values ranging from $-l$ to l, including 0. Subscripts can be used to label the orientations of the orbitals. For example, the three $3p$ orbitals are designated $3p_x$, $3p_y$, and $3p_z$, with the subscripts indicating the axis along which the orbital is oriented.

An electron shell is the set of all orbitals with the same value of n, such as $3s$, $3p$, and $3d$. In the hydrogen atom all the orbitals in an electron shell have the same energy. A **subshell** is the set of one or more orbitals with the same n and l values; for example, 3s, $3p$, and $3d$ are each subshells of the $n = 3$ shell. There is one orbital in an s subshell, three in a p subshell, five in a d subshell, and seven in an f subshell.

REPRESENTATIONS OF ORBITALS (SECTION 6.6) The **radial probability function** $4\pi r^2[\psi(r)]^2$ tells us the probability that the electron will be found at a certain distance from the nucleus. Points where the wave function changes sign are called **nodes**. There is zero probability that the electron will be found at a node because the wave function equals zero and so the radial probability function is also zero at a node. Nodes that occur at a given distance from the nucleus are called **radial nodes**. They are spherical in shape, and their number increases as the value of the principal quantum number, n, increases. Contour representations are surfaces that are useful for visualizing the shapes of the orbitals. Represented in this way, s orbitals appear as spheres that increase in size as n increases.

The wave function for each p orbital has two lobes on opposite sides of the nucleus. They are oriented along either the x, y, or z axis. The two nodes are separated by a **nodal plane**, where the probability of finding the electron goes to zero. Four of the five d orbitals have contour representations with four lobes around the nucleus, due to the presence of two perpendicular nodal planes, whereas the angular nodes for the d_{z^2} orbital are cones, which produce a contour surface with two lobes along the z axis and a "doughnut" in the xy plane.

MANY-ELECTRON ATOMS (SECTION 6.7) In many-electron atoms, different subshells of the same electron shell have different energies. For a given value of n, the energy of the subshells increases as the value of l increases: $ns < np < nd < nf$. Orbitals within the same subshell are **degenerate**, meaning they have the same energy.

Electrons have an intrinsic property called **electron spin**, which is quantized. The **spin magnetic quantum number**, m_s, can have two possible values, $+\frac{1}{2}$ and $-\frac{1}{2}$, which can be envisioned as the two directions of an electron spinning about an axis. The **Pauli exclusion principle** states that no two electrons in an atom can have the same values for n, l, m_l, and m_s. This principle places a limit of two on the number of electrons that can occupy any one atomic orbital. These two electrons differ in their value of m_s.

ELECTRON CONFIGURATIONS AND THE PERIODIC TABLE (SECTIONS 6.8 AND 6.9) The **electron configuration** of an atom describes how the electrons are distributed among the orbitals of the atom. The ground-state electron configurations are generally obtained by placing the electrons in the atomic orbitals of lowest possible energy, with the restriction that each orbital can hold no more than two electrons. We depict the arrangement of the electrons pictorially using an **orbital diagram**. When electrons occupy a subshell with more than one degenerate orbital, such as the $2p$ subshell, **Hund's rule** states that the lowest energy is attained by maximizing the number of electrons with the same electron spin. For example, in the ground-state electron configuration of carbon, the two $2p$ electrons have the same spin and must occupy two different $2p$ orbitals.

Elements in any given group in the periodic table have the same type of electron arrangements in their outermost shells. For example, the electron configurations of the halogens fluorine and chlorine are $[\mathrm{He}]2s^22p^5$ and $[\mathrm{Ne}]3s^23p^5$, respectively. The outer-shell electrons are those that lie outside the orbitals occupied in the next lowest noble-gas element. The outer-shell electrons that are involved in chemical bonding are the **valence electrons** of an atom; for the elements with atomic number 30 or less, all of the outer-shell electrons are valence electrons. The electrons that are not valence electrons are called **core electrons**.

The periodic table is partitioned into different types of elements, based on their electron configurations. Those elements in which the outermost subshell is an s or p subshell are called the **representative** (or **main-group**) **elements**. Those elements in which a d subshell is being filled are called the **transition elements** (or **transition metals**). The elements in which the $4f$ subshell is being filled are called the **lanthanide** (or **rare earth**) **elements**. The actinide elements are those in which the $5f$ subshell is being filled. The lanthanide and **actinide elements** are collectively referred to as the ***f*-block metals**. These elements are shown as two rows of 14 elements below the main part of the periodic table. The structure of the periodic table, summarized in Figure 6.28, allows us to write the electron configuration of an element from its position in the periodic table.

Key Equations

• $\lambda\nu = c$	[6.1]	light as a wave: λ = wavelength in meters, ν = frequency in s^{-1}, c = speed of light (2.998×10^8 m/s)
• $E = h\nu$	[6.2]	light as a particle (photon): E = energy of photon in joules, h = Planck constant (6.626×10^{-34} J-s), ν = frequency in s^{-1}
• $\dfrac{1}{\lambda} = (R_H)\left(\dfrac{1}{n_1^2} - \dfrac{1}{n_2^2}\right)$	[6.4]	The Rydberg equation which gives the wavelengths of light λ (in m) in the line spectrum of the hydrogen atom: R_H = Rydberg constant ($1.096776 \times 10^7\ m^{-1}$); $n = 1, 2, 3, \ldots$ (any positive integer).
• $E = (-hcR_H)\left(\dfrac{1}{n^2}\right) = (-2.18 \times 10^{-18} J)\left(\dfrac{1}{n^2}\right)$	[6.5]	energies of the allowed states of the hydrogen atom: h = Planck constant; c = speed of light; R_H = Rydberg constant ($1.096776 \times 10^7\ m^{-1}$); $n = 1, 2, 3, \ldots$ (any positive integer)
• $\lambda = h/mv$	[6.8]	matter as a wave: λ = wavelength, h = Planck constant, m = mass of object in kg, v = speed of object in m/s
• $\Delta x \cdot \Delta(mv) \geq \dfrac{h}{4\pi}$	[6.9]	Heisenberg's uncertainty principle. The uncertainty in position (Δx) and momentum [$\Delta(mv)$] of an object cannot be zero; the smallest value of their product is $h/4\pi$.

Exam Prep

EP 6.1 A source of electromagnetic radiation produces infrared light. Which of the following could be the wavelength of the light? (**a**) 3.0 nm (**b**) 4.7 cm (**c**) 66.8 m (**d**) 34.5 μm (**e**) 16.5 Å

EP 6.2 The ________ of ultraviolet radiation is greater than that of microwave radiation, but the ________ of the two types of electromagnetic radiation are the same. (**a**) wavelength, speed (**b**) speed, wavelength (**c**) frequency, speed (**d**) speed, frequency (**e**) frequency, wavelength

EP 6.3 Cellular phones use radio waves to transmit information. If your cell phone uses a frequency of 1900 MHz, what is the wavelength of the electromagnetic radiation emitted by your phone? (**a**) 5.7×10^{17} m (**b**) 0.16 m (**c**) 1.6×10^5 m (**d**) 6.3 m

EP 6.4 If electrons are ejected from a given metal when irradiated with a red laser pointer, what will happen when the same metal is irradiated with a green laser pointer of comparable intensity? (**a**) Electrons will be emitted, and the maximum kinetic energies of those electrons will be similar to those emitted when irradiated with the red laser pointer. (**b**) Electrons will be emitted, and the maximum kinetic energies of those electrons will be greater than those emitted when irradiated with the red laser pointer. (**c**) Electrons will be emitted, and the maximum kinetic energies of those electrons will be less than those emitted when irradiated with the red laser pointer. (**d**) Electrons will not be emitted.

EP 6.5 Which of the following expressions correctly gives the energy of a mole of photons with wavelength λ?

(**a**) $E = \dfrac{h}{\lambda}$

(**b**) $E = N_A\dfrac{\lambda}{h}$

(**c**) $E = \dfrac{hc}{\lambda}$

(**d**) $E = N_A\dfrac{h}{\lambda}$

(**e**) $E = N_A\dfrac{hc}{\lambda}$

EP 6.6 Consider the electronic transitions in the Bohr model that give rise to the line spectrum of hydrogen. What characteristic feature do the four visible colors of light that fall in the visible portion of the spectrum (λ = 410 nm, 434 nm, 486 nm, and 656 nm) have in common? (**a**) They all have $n_f = 1$. (**b**) They all have $n_f = 2$. (**c**) They all have $n_f = 3$. (**d**) They all have $n_i = 2$. (**e**) They all have $n_i = 3$.

EP 6.7 In the Bohr model of the hydrogen atom, the electron orbits the nucleus at a fixed radius of 0.53 Å when in the ground state. This model is a violation of which scientific principle that followed? (**a**) the Pauli exclusion principle (**b**) the uncertainty principle (**c**) Hund's rule (**d**) both the Pauli exclusion principle and the uncertainty principle (**e**) both the Pauli exclusion principle and Hund's rule

EP 6.8 Arrange the following objects in order of increasing de Broglie wavelength:

(**i**) a golf ball with a mass of 45.9 g moving at a speed of 50 m/s,

(**ii**) an electron with a mass of 9.109×10^{-31} kg moving at a speed of 3.50×10^5 m/s, and

(**iii**) a neutron with a mass of 1.675×10^{-27} kg moving at a speed of 2.3×10^2 m/s.

(**a**) i < iii < ii (**b**) ii < iii < i (**c**) iii < ii < i (**d**) i < ii < iii (**e**) iii < i < ii

EP 6.9 The average speed of an N_2 gas molecule in a container with a temperature of 100 °C is 500 m/s. If the uncertainty in our measurement of the molecule's speed is 1% (5 m/s), what is the *lower limit* on the uncertainty with which we can measure its position?

(**a**) 1.2×10^{-5} m

(**b**) 2.3×10^{-10} m

(**c**) 2.3×10^{-13} m

(**d**) 3.8×10^{-37} m

EP 6.10 Which of the following descriptions applies to Schrödinger's model *but not* Bohr's model of the hydrogen atom?

(**i**) The angular momentum of the electron is quantized and represented by the quantum number *l*.

(**ii**) The energy level of the electron depends only on the principal quantum number, *n*.

(**iii**) The distance between the electron and the nucleus cannot be specified because of the wave-like properties of the electron.

(**a**) only i (**b**) only ii (**c**) only iii (**d**) both i and iii (**e**) All three statements are true.

EP 6.11 Which aspect of the Bohr model is *not* consistent with our current understanding of how the electron in a hydrogen atom behaves? (**a**) The allowed energy levels of the electron are quantized. (**b**) A photon is emitted when the electron transitions from a higher-energy state to a lower-energy state. (**c**) The electron moves in a circular orbit around the nucleus. (**d**) As the energy of the electron increases, it experiences a weaker attraction to the nucleus.

EP 6.12 What are the principal and angular momentum quantum numbers for the lowest energy *f* orbital subshell? (**a**) $n = 1, l = 3$ (**b**) $n = 3, l = 3$ (**c**) $n = 4, l = 1$ (**d**) $n = 4, l = 3$ (**e**) $n = 4, l = 4$

EP 6.13 Consider two atomic orbitals, the first defined by the quantum numbers $n = 2, l = 1, m_l = 0$, while the second orbital has the quantum numbers $n = 2$, $l = 1$, $m_l = 1$. Which of the following statements comparing the two orbitals is or are true?

(**i**) The two orbitals have the same energy.

(**ii**) The two orbitals have the same shape.

(**iii**) The two orbitals have the same orientation.

(**a**) only i (**b**) both i and ii (**c**) both i and iii (**d**) both ii and iii (**e**) All three statements are true.

EP 6.14 An orbital has $n = 4$ and $m_l = -1$. What are the possible values of l for this orbital? (**a**) 0, 1, 2, 3 (**b**) −3, −2, −1, 0, 1, 2, 3 (**c**) 1, 2, 3 (**d**) −3, −2 (**e**) 1, 2, 3, 4

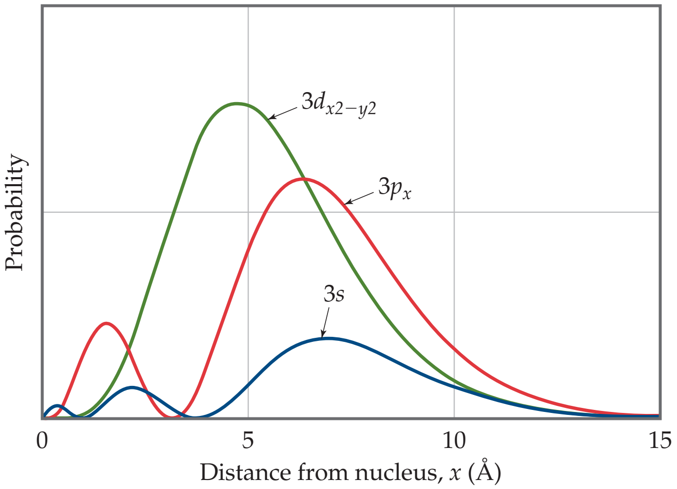
EP 6.15 The plots shown here map the probability of finding an electron in either a 3*s*, $3p_x$, or $3d_{x^2-y^2}$ orbital of the hydrogen atom, each plotted as a function of distance along the *x* axis. Which of the following statements is or are true?

(**i**) The 3*s* orbital has more radial nodes than the $3p_x$ orbital.

(**ii**) The most probable location of the 3*s* orbital is closer to the nucleus than the most probable location of the $3d_{x^2-y^2}$ orbital.

(**iii**) An electron in the 3*s* orbital has a higher probability of being found very close to the nucleus ($r < 1$Å) than an electron in the $d_{x^2-y^2}$ orbital.

(**a**) only i (**b**) both i and ii (**c**) both i and iii (**d**) both ii and iii (**e**) All three statements are true



EP 6.16 Which type of atomic orbital can be described as having two lobes of electron density separated by a nodal plane? (**a**) *s* (**b**) *p* (**c**) *d* (**d**) *f*

EP 6.17 Consider three electrons in a sodium atom, with the following quantum numbers:

electron 1: $n = 3, l = 0, m_l = 0, m_s = +\frac{1}{2}$
electron 2: $n = 2, l = 1, m_l = 1, m_s = -\frac{1}{2}$
electron 3: $n = 2, l = 1, m_l = 0, m_s = +\frac{1}{2}$

Which electron has the lowest energy? (**a**) electron 1 (**b**) electron 2 (**c**) electron 3 (**d**) electrons 2 and 3, which are degenerate and lower in energy than electron 1 (**e**) electrons 1 and 3, which are degenerate and lower in energy than electron 2

EP 6.18 Given the constraints of the Pauli exclusion principle, what is the maximum number of electrons that can occupy the 4*d* subshell? (**a**) 4 (**b**) 5 (**c**) 6 (**d**) 10 (**e**) 14

EP 6.19 In which of the following atoms—Ti, Ca, or C—do the spin magnetic quantum numbers of all the electrons sum to zero and therefore does not possess a magnetic moment? Assume each atom is in its ground-state electron configuration. (**a**) only Ti (**b**) only Ca (**c**) only C (**d**) Ti and Ca (**e**) all three atoms

EP 6.20 What is the condensed electron configuration for the element osmium ($Z = 76$)?

(**a**) $[\mathrm{Kr}]5s^2 4f^{14} 4d^6$
(**b**) $[\mathrm{Kr}]6s^2 4f^{14} 5d^6$
(**c**) $[\mathrm{Xe}]6s^2 5d^6$
(**d**) $[\mathrm{Xe}]6s^2 4f^{14} 5d^6$
(**e**) $[\mathrm{Xe}]5s^2 4f^{14} 5d^6$

EP 6.21 How many of the elements in the second row of the periodic table (Li through Ne) will have at least one unpaired electron in their electron configurations? (**a**) 3 (**b**) 4 (**c**) 5 (**d**) 6 (**e**) 7

EP 6.22 Which element has a [noble-gas]$5s^2 4d^{10} 5p^4$ electron configuration? (**a**) Cd (**b**) Te (**c**) Sm (**d**) Hg (**e**) Se

EP 6.23 A certain atom has an ns^2np^6 electron configuration in its outermost occupied shell. Which of the following elements could it be? (**a**) Be (**b**) Si (**c**) I (**d**) Ar (**e**) Rb

EP 6.24 The organization of the periodic table tells us that the 5*f* subshell is filled after the ________ subshell and before the ________ subshell. (**a**) 4*f*, 6*f* (**b**) 5*d*, 5*g* (**c**) 6*s*, 5*d* (**d**) 7*s*, 7*d* (**e**) 7*s*, 6*d*

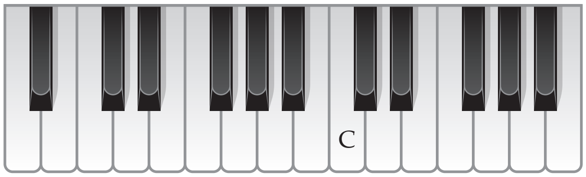
EP 6.25 The element samarium ($Z = 62$) is ________ with a partially filled ________ subshell. (**a**) an *f*-block metal, 4*f* (**b**) an *f*-block metal, 5*f* (**c**) a transition metal, 4*d* (**d**) a transition metal, 5*d* (**e**) a representative element, 4*f*

EP 6.26 An element has a [noble gas]$ns^2(n-2)f^{14}(n-1)d^{10}np^2$ electron configuration. In which region of the periodic table will this element be found? (**a**) representative elements (**b**) *f*-block metals (**c**) transition metals (**d**) noble gases

Exercises

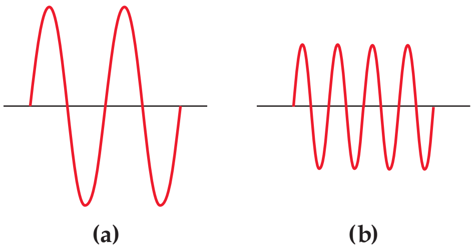
Visualizing Concepts

6.1 The speed of sound in dry air at 20 °C is 343 m/s, and the middle C on a piano keyboard has a frequency of 261 Hz. (**a**) What is the wavelength of the sound wave corresponding to a middle C? (**b**) What would be the frequency of electromagnetic radiation with the same wavelength? (**c**) What type of electromagnetic radiation would that correspond to? (**d**) Do sound waves travel faster, slower, or at the same speed as electromagnetic radiation? [Section 6.1]



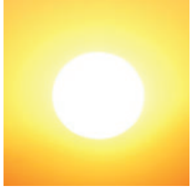
6.2 A popular kitchen appliance produces electromagnetic radiation with a frequency of 2450 MHz. With reference to Figure 6.4, answer the following: (**a**) Estimate the wavelength of this radiation. (**b**) Would the radiation produced by the appliance be visible to the human eye? (**c**) If the radiation is not visible, do photons of this radiation have more or less energy than photons of visible light? (**d**) Which of the following is the appliance likely to be? (i) a toaster oven, (ii) a microwave oven, or (iii) an electric hotplate. [Section 6.1]

6.3 The following diagrams represent two electromagnetic waves, drawn on the same scale. (**a**) Which wave has a longer wavelength? (**b**) Which wave has a higher frequency? (**c**) Which wave has a higher energy? [Section 6.2]

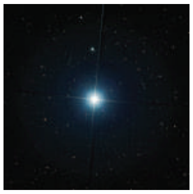


(a) **(b)**

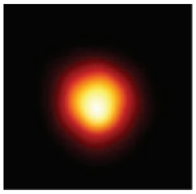
6.4 Stars do not all have the same temperature. The color of light emitted by stars is characteristic of the light emitted by hot objects. Telescopic photos of three stars are shown below: (i) the Sun, which is classified as a *yellow* star, (ii) *Rigel*, in the constellation Orion, which is classified as a *blue-white* star, and (iii) *Betelgeuse*, also in Orion, which is classified as a *red* star. (**a**) Place these three stars in order of increasing temperature. (**b**) Which of the following principles is relevant to your choice of answer for part (a): the uncertainty principle, the photoelectric effect, blackbody radiation, or line spectra? [Section 6.2]



(i) Sun



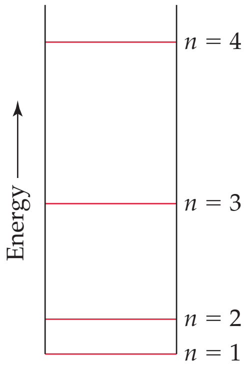
(ii) Rigel



(iii) Betelgeuse

6.5 The familiar phenomenon of a rainbow results from the diffraction of sunlight through raindrops. (**a**) Does the wavelength of light increase or decrease as we proceed outward from the innermost band of the rainbow? (**b**) Does the frequency of light increase or decrease as we proceed outward? [Section 6.3]

6.6 A certain quantum-mechanical system has the energy levels shown in the accompanying diagram. The energy levels are indexed by a single quantum number n that is an integer. (**a**) As drawn, which quantum numbers are involved in the transition that requires the most energy? (**b**) Which quantum numbers are involved in the transition that requires the least energy? (**c**) Based on the drawing, put the following in order of increasing wavelength of the light absorbed during the transition: (i) $n = 1$ to $n = 2$, (ii) $n = 2$ to $n = 3$, (iii) $n = 2$ to $n = 4$. (iv) $n = 1$ to $n = 3$. [Section 6.3]

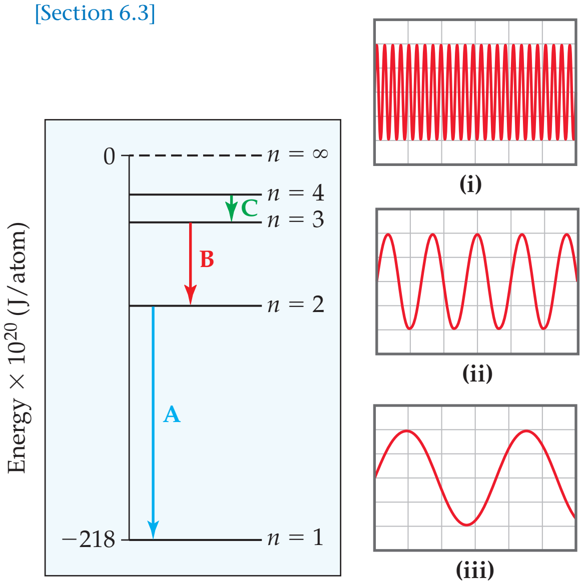


6.7 Consider the three electronic transitions in a hydrogen atom shown here, labeled A, B, and C.

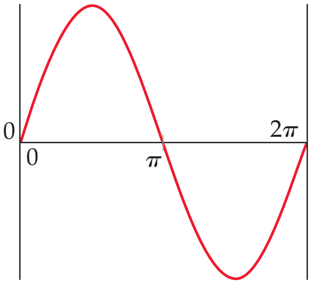
(**a**) Three electromagnetic waves, all drawn on the same scale, are also shown. Each corresponds to one of the transitions. Which electromagnetic wave—(i), (ii), or (iii)—is associated with electronic transition C?

(**b**) Calculate the energy of the photon emitted for each transition.

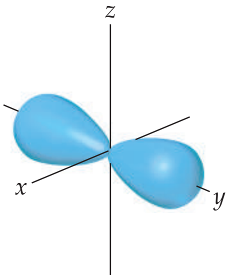
(**c**) Calculate the wavelength of the photon emitted for each transition. Do any of these transitions lead to the emission of visible light? If so, which one(s)? [Section 6.3]



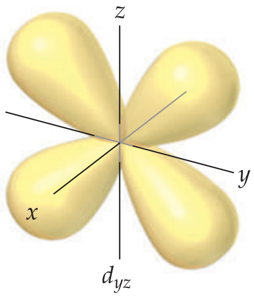
6.8 Consider a fictitious one-dimensional system with one electron. The wave function for the electron, drawn below, is $\psi(x) = \sin x$ from $x = 0$ to $x = 2\pi$. (**a**) Sketch the probability density, $\psi^2(x)$, from $x = 0$ to $x = 2\pi$. (**b**) At what value or values of x will there be the greatest probability of finding the electron? (**c**) What is the probability that the electron will be found at $x = \pi$? What is such a point in a wave function called? [Section 6.5]



6.9 The contour representation of one of the orbitals for the $n = 3$ shell of a hydrogen atom is shown here. (**a**) What is the quantum number l for this orbital? (**b**) How do we label this orbital? (**c**) In which of the following ways would you modify this sketch if the value of the magnetic quantum number, m_l, were to change? (i) It would be drawn larger, (ii) the number of lobes would change, (iii) the lobes of the orbital would point in a different direction, (iv) there would be no change in the sketch. [Section 6.6]

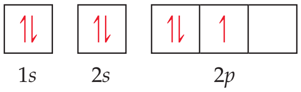


6.10 The accompanying drawing shows a contour plot for a d_{yz} orbital. Consider the quantum numbers that could potentially correspond to this orbital. (**a**) What is the smallest possible value of the principal quantum number, n? (**b**) What is the value of the angular momentum quantum number, l? (**c**) What is the largest possible value of the magnetic quantum number, m_l? (**d**) The probability density goes to zero along which of the following planes: xy, xz, or yz?

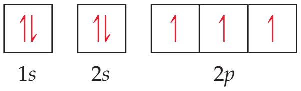


6.11 Four possible electron configurations for a nitrogen atom are shown below, but only one schematic represents the correct configuration for a nitrogen atom in its ground state. Which one is the correct electron configuration? Which configurations violate the Pauli exclusion principle? Which configurations violate Hund's rule? [Section 6.8]

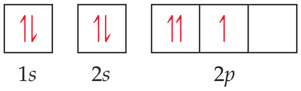
Configuration A



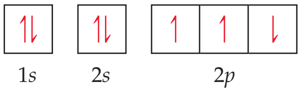
Configuration B



Configuration C



Configuration D



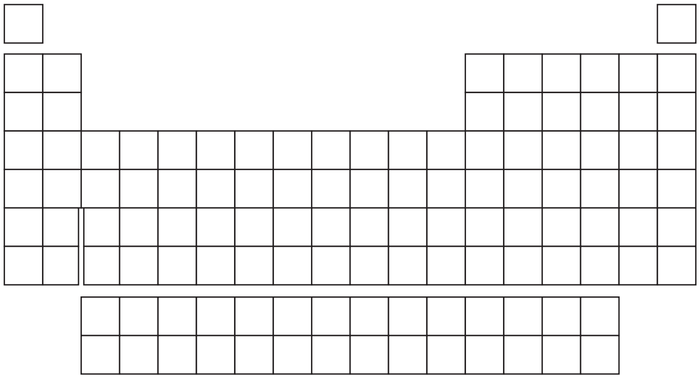
6.12 State where in the periodic table these elements appear.

(**a**) elements with the valence-shell electron configuration ns^2np^5

(**b**) elements that have three unpaired p electrons

(**c**) an element whose valence electrons are $4s^24p^1$

(**d**) the d-block elements [Section 6.9]



The Wave Nature of Light (Section 6.1)

6.13 What are the basic SI units for (**a**) the wavelength of light, (**b**) the frequency of light, (**c**) the speed of light?

6.14 (**a**) What is the relationship between the wavelength and the frequency of radiant energy? (**b**) Ozone in the upper atmosphere absorbs energy in the 210–230-nm range of the spectrum. In what region of the electromagnetic spectrum does this radiation occur?

6.15 Label each of the following statements as true or false. (**a**) Visible light is a form of electromagnetic radiation. (**b**) Ultraviolet light has longer wavelengths than visible light. (**c**) X rays travel faster than microwaves. (**d**) Electromagnetic radiation and sound waves travel at the same speed.

6.16 Label each of the following statements as true or false. (**a**) The frequency of radiation increases as the wavelength increases. (**b**) Electromagnetic radiation travels through a vacuum at a constant speed, regardless of wavelength. (**c**) Infrared light has higher frequencies than visible light. (**d**) The glow from a fireplace, the energy within a microwave oven, and a foghorn blast are all forms of electromagnetic radiation.

6.17 Arrange the following kinds of electromagnetic radiation in order of increasing wavelength: infrared light, green light, red light, radio waves, X rays, ultraviolet light.

6.18 List the following types of electromagnetic radiation in order of increasing wavelength: (**a**) the gamma rays produced by a radioactive nuclide used in medical imaging; (**b**) radiation from an FM radio station at 93.1 MHz on the dial; (**c**) a radio signal from an AM radio station at 680 kHz on the dial; (**d**) the yellow light from sodium vapor streetlights; (**e**) the red light of a light-emitting diode, such as in a calculator display.

6.19 (**a**) What is the frequency of radiation that has a wavelength of 10 μm, about the size of a bacterium? (**b**) What is the wavelength of radiation that has a frequency of $5.50 \times 10^{14} s^{-1}$? (**c**) Would the radiations in part (a) or part (b) be visible to the human eye? (**d**) What distance does electromagnetic radiation travel in 50.0 μs?

6.20 (**a**) What is the frequency of radiation whose wavelength is 0.86 nm? (**b**) What is the wavelength of radiation that has a frequency of $6.4 \times 10^{11} s^{-1}$? (**c**) Would the radiations in part (a) or part (b) be detected by an X-ray detector? (**d**) What distance does electromagnetic radiation travel in 0.38 ps?

6.21 A laser pointer used in a lecture hall emits light at 650 nm. What is the frequency of this radiation? Using Figure 6.4, predict the color associated with this wavelength.

6.22 It is possible to convert radiant energy into electrical energy using photovoltaic cells. Assuming equal efficiency of conversion, would infrared or ultraviolet radiation yield more electrical energy on a per-photon basis?

Quantized Energy and Photons (Section 6.2)

6.23 If human height were quantized in 1-foot increments, what would happen to the height of a child as she grew up? (**a**) The child's height would never change. (**b**) The child's height would continuously get greater. (**c**) The child's height would increase in "jumps" of 1 foot at a time. (**d**) The child's height would increase in jumps of 6 inches.

6.24 When an object like a piece of graphite is heated to 1000 K, it glows red. When the temperature is increased to around 3000 K, the color of emitted light becomes orange. What is the reason for this change in color? (**a**) The speed of the photons (quantized packets of radiant energy) increases with increasing temperature. (**b**) The average wavelength of the photons emitted increases with increasing temperature. (**c**) The average energy of the photons emitted increases as the temperature increases.

6.25 (**a**) Calculate the energy of a photon of electromagnetic radiation whose frequency is $2.94 \times 10^{14}\ s^{-1}$. (**b**) Calculate the energy of a photon of radiation whose wavelength is 413 nm. (**c**) What wavelength of radiation has photons of energy 6.06×10^{-19} J?

6.26 (**a**) A green laser pointer emits light with a wavelength of 532 nm. What is the frequency of this light? (**b**) What is the energy of one of these photons? (**c**) The laser pointer emits light because electrons in the material are excited (by a battery) from their ground state to an upper excited state. When the electrons return to the ground state, they lose the excess energy in the form of 532-nm photons. What is the energy gap between the ground state and excited state in the laser material?

6.27 (**a**) Calculate and compare the energy of a photon of wavelength 3.3 μm with that of wavelength 0.154 nm. (**b**) Use Figure 6.4 to identify the region of the electromagnetic spectrum to which each belongs.

6.28 An AM radio station broadcasts at 1010 kHz, and its FM partner broadcasts at 98.3 MHz. Calculate and compare the energy of the photons emitted by these two radio stations.

6.29 One type of sunburn occurs on exposure to UV light of wavelength in the vicinity of 325 nm. (**a**) What is the energy of a photon of this wavelength? (**b**) What is the energy of a mole of these photons? (**c**) How many photons are in a 1.00-mJ burst of this radiation? (**d**) These UV photons can break chemical bonds in your skin to cause sunburn—a form of radiation damage. If the 325-nm radiation provides exactly the energy to break an average chemical bond in the skin, estimate the average energy of these bonds in kJ/mol.

6.30 The energy from radiation can be used to cause the rupture of chemical bonds. A minimum energy of 242 kJ/mol is required to break the chlorine–chlorine bond in Cl_2. What is the longest wavelength of radiation that possesses the necessary energy to break the bond? What type of electromagnetic radiation is this?

6.31 A diode laser emits at a wavelength of 987 nm. (**a**) In what portion of the electromagnetic spectrum is this radiation found? (**b**) All of its output energy is absorbed in a detector that measures a total energy of 0.52 J over a period of 32 s. How many photons per second are being emitted by the laser?

6.32 A stellar object is emitting radiation at 3.55 mm. (**a**) What type of electromagnetic spectrum is this radiation? (**b**) If a detector is capturing 3.2×10^8 photons per second at this wavelength, what is the total energy of the photons detected in 1.0 hour?

6.33 Molybdenum metal must absorb radiation with a minimum frequency of $1.09 \times 10^{15}\ s^{-1}$ before it can eject an electron from its surface via the photoelectric effect. (**a**) What is the minimum energy needed to eject an electron? (**b**) What wavelength of radiation will provide a photon of this energy? (**c**) If molybdenum is irradiated with light of wavelength of 120 nm, what is the maximum possible kinetic energy of the emitted electrons?

6.34 Titanium metal requires a photon with a minimum energy of 6.94×10^{-19} J to emit electrons. (**a**) What is the minimum frequency of light necessary to emit electrons from titanium via the photoelectric effect? (**b**) What is the wavelength of this light? (**c**) Is it possible to eject electrons from titanium metal using visible light? (**d**) If titanium is irradiated with light of wavelength 233 nm, what is the maximum possible kinetic energy of the emitted electrons?

Bohr's Model; Matter Waves (Sections 6.3 and 6.4)

6.35 Does the hydrogen atom "expand" or "contract" when an electron is excited from the $n = 1$ state to the $n = 3$ state?

6.36 Classify each of the following statements as either true or false. (**a**) A hydrogen atom in the $n = 3$ state can emit light at only two specific wavelengths, (**b**) a hydrogen atom in the $n = 2$ state is at a lower energy than one in the $n = 1$ state, and (**c**) the energy of an emitted photon equals the energy difference of the two states involved in the emission.

6.37 Is energy emitted or absorbed when the following electronic transitions occur in hydrogen: (**a**) from $n = 4$ to $n = 2$, (**b**) from an orbit of radius 2.12 Å to one of radius 8.46 Å, (**c**) an electron adds to the H^+ ion and ends up in the $n = 3$ shell?

6.38 Indicate whether energy is emitted or absorbed when the following electronic transitions occur in hydrogen: (**a**) from $n = 3$ to $n = 6$, (**b**) from an orbit of radius 4.76 Å to one of radius 0.529 Å, (**c**) from the $n = 6$ to the $n = 9$ state.

6.39 (**a**) Using Equation 6.5, calculate the energy of an electron in the hydrogen atom when $n = 2$ and when $n = 6$. Calculate the wavelength of the radiation released when an electron moves from $n = 6$ to $n = 2$. (**b**) Is this line in the visible region of the electromagnetic spectrum? If so, what color is it?

6.40 Consider a transition of the electron in the hydrogen atom from $n = 4$ to $n = 9$. (**a**) Is ΔE for this process positive or negative? (**b**) Determine the wavelength of light that is associated with this transition. Will the light be absorbed or emitted? (**c**) In which portion of the electromagnetic spectrum is the light in part (b)?

6.41 The visible emission lines observed by Balmer all involved $n_f = 2$. (**a**) Which of the following is the best explanation of why the lines with $n_f = 3$ are not observed in the visible portion of the spectrum: (i) Transitions to $n_f = 3$ are not allowed to happen, (ii) transitions to $n_f = 3$ emit photons in the infrared portion of the spectrum, (iii) transitions to $n_f = 3$ emit photons in the ultraviolet portion of the spectrum, or (iv) transitions to $n_f = 3$ emit photons that are at exactly the same wavelengths as those to $n_f = 2$. (**b**) Calculate the wavelengths of the first three lines in the Balmer series—those for which $n_i = 3$, 4, and 5—and identify these lines in the emission spectrum shown in Figure 6.11.

6.42 The Lyman series of emission lines of the hydrogen atom are those for which $n_f = 1$. (**a**) Determine the region of the electromagnetic spectrum in which the lines of the Lyman series are observed. (**b**) Calculate the wavelengths of the first three lines in the Lyman series—those for which $n_i = 2$, 3, and 4.

6.43 One of the emission lines of the hydrogen atom has a wavelength of 93.07 nm. (**a**) In what region of the electromagnetic spectrum is this emission found? (**b**) Determine the initial and final values of n associated with this emission.

6.44 The hydrogen atom can absorb light of wavelength 1094 nm. (**a**) In what region of the electromagnetic spectrum is this absorption found? (**b**) Determine the initial and final values of n associated with this absorption.

6.45 Order the following transitions in the hydrogen atom from smallest to largest frequency of light absorbed: $n = 3$ to $n = 6$, $n = 4$ to $n = 9$, $n = 2$ to $n = 3$, and $n = 1$ to $n = 2$.

6.46 Place the following transitions of the hydrogen atom in order from shortest to longest wavelength of the photon emitted: $n = 5$ to $n = 3$, $n = 4$ to $n = 2$, $n = 7$ to $n = 4$, and $n = 3$ to $n = 2$.

6.47 Use the de Broglie relationship to determine the wavelengths of the following objects: (**a**) an 85-kg person skiing at 50 km/hr, (**b**) a 10.0-g bullet fired at 250 m/s, (**c**) a lithium atom moving at 2.5×10^5 m/s, (**d**) an ozone (O_3) molecule in the upper atmosphere moving at 550 m/s.

6.48 Among the elementary subatomic particles of physics is the muon, which decays within a few microseconds after formation. The muon has a rest mass 206.8 times that of an electron. Calculate the de Broglie wavelength associated with a muon traveling at 8.85×10^5 cm/s.

6.49 Neutron diffraction is an important technique for determining the structures of molecules. Calculate the velocity of a neutron needed to achieve a wavelength of 1.25 Å. The mass of a neutron is 1.675×10^{-27} kg.

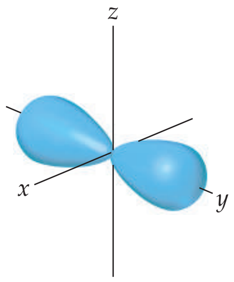
6.50 The electron microscope has been widely used to obtain highly magnified images of biological and other types of materials. When an electron is accelerated through a particular potential field, it attains a speed of 9.47×10^6 m/s. What is the characteristic wavelength of this electron? Is the wavelength comparable to the size of atoms?

6.51 Using Heisenberg's uncertainty principle, calculate the uncertainty in the position of (**a**) a 1.50-mg mosquito moving at a speed of 1.40 m/s if the speed is known to within ± 0.01 m/s; (**b**) a proton moving at a speed of $(5.00 \pm 0.01) \times 10^4$ m/s. The mass of a proton is 1.673×10^{-27} kg.

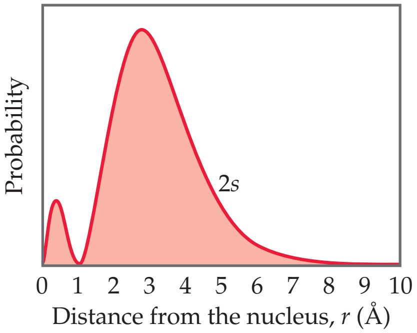
6.52 Calculate the uncertainty in the position of (**a**) an electron moving at a speed of $(3.00 \pm 0.01) \times 10^5$ m/s, (**b**) a neutron moving at this same speed. (The masses of the electron and neutron are 9.109×10^{-31} kg and 1.675×10^{-27} kg, respectively.) (**c**) Based on your answers to parts (a) and (b), which can we know with greater precision, the position of the electron or the position of the neutron?

Quantum Mechanics and Atomic Orbitals (Sections 6.5 and 6.6)

6.53 Classify the following statements as either true or false: (**a**) In a contour representation of an orbital, such as the one shown here for a 2*p* orbital, the electron is confined to move about the nucleus on the outer surface of the shape. (**b**) The probability density $[\psi(r)]^2$ gives the probability of finding the electron at a specific distance from the nucleus.



6.54 The radial probability function for a 2*s* orbital is shown here. Classify the following statements as either true or false. (**a**) There are two maxima in this function because one electron spends most of its time at an approximate distance of 0.5 Å from the nucleus and the other electron spends most of its time at an approximate distance of 3 Å from the nucleus. (**b**) The radial probability function shown here and the probability density $[\psi(r)]^2$ both go to zero at the same distance from the nucleus, approximately 1 Å. (**c**) For an *s* orbital, the number of radial nodes is equal to the principal quantum number, *n*.



6.55 (**a**) For $n = 4$, what are the possible values of *l*? (**b**) For $l = 2$, what are the possible values of m_l? (**c**) If m_l is 2, what are the possible values for *l*?

6.56 How many unique combinations of the quantum numbers *l* and m_l are there when (**a**) $n = 3$, (**b**) $n = 4$?

6.57 Give the numerical values of *n* and *l* corresponding to each of the following orbital designations: (**a**) 3*p*, (**b**) 2*s*, (**c**) 4*f*, (**d**) 5*d*.

6.58 Give the values for *n*, *l*, and m_l for (**a**) each orbital in the 2*p* subshell and (**b**) each orbital in the 5*d* subshell.

6.59 A certain orbital of the hydrogen atom has $n = 4$ and $l = 2$. (**a**) What are the possible values of m_l for this orbital? (**b**) What are the possible values of m_s for the orbital?

6.60 A hydrogen atom orbital has $n = 5$ and $m_l = -2$. (**a**) What are the possible values of *l* for this orbital? (**b**) What are the possible values of m_s for the orbital?

6.61 Which of the following represent impossible combinations of *n* and *l*: (**a**) 1*p*, (**b**) 4*s*, (**c**) 5*f*, (**d**) 2*d*?

6.62 For the table that follows, write which orbital goes with the quantum numbers. Don't worry about *x*, *y*, *z* subscripts. If the quantum numbers are not allowed, write "not allowed."

n	l	m_l	Orbital
2	1	−1	2*p* (example)
1	0	0	
3	−3	2	
3	2	−2	
2	0	−1	
0	0	0	
4	2	1	
5	3	0	

6.63 Sketch the shape and orientation of the following types of orbitals: (**a**) *s*, (**b**) p_z, (**c**) d_{xy}.

6.64 Sketch the shape and orientation of the following types of orbitals: (**a**) p_x, (**b**) d_{z^2}, (**c**) $d_{x^2-y^2}$.

6.65 (**a**) How many radial nodes are there in the 4*s* orbital of the hydrogen atom? (**b**) How many nodal planes are there in a $2p_x$ orbital of the hydrogen atom? (**c**) Is the most probable distance from the nucleus of an electron in a 2*s* orbital larger or smaller than it would be for an electron in a 3*s* orbital? (**d**) For the hydrogen atom, list the following orbitals in order of increasing energy (that is, most stable ones first): 4*f*, 6*s*, 3*d*, 1*s*, 2*p*.

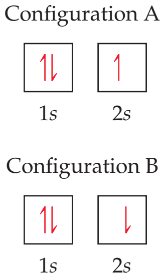
6.66 (**a**) With reference to Figure 6.19, what is the relationship between the number of nodes in an *s* orbital and the value of the principal quantum number? (**b**) If you were to plot all the points that lie on the node of the 2*s* orbital wave function, what shape would you obtain: a set of isolated points, a plane, or a sphere? (**c**) Do any atomic orbitals have a maximum in their radial probability function at the nucleus? If so which orbital or orbitals?

Many-Electron Atoms and Electron Configurations (Sections 6.7–6.9)

6.67 (**a**) For an He^+ ion, do the 2*s* and 2*p* orbitals have the same energy? If not, which orbital has a lower energy? (**b**) If we add one electron to form the He atom, would your answer to part (a) change?

6.68 (**a**) The average distance from the nucleus of a 3*s* electron in a chlorine atom is smaller than that for a 3*p* electron. In light of this fact, which orbital is higher in energy? (**b**) Would you expect it to require more or less energy to remove a 3*s* electron from the chlorine atom as compared with a 2*p* electron?

6.69 Two possible electron configurations for an Li atom are shown here. (**a**) Does either configuration violate the Pauli exclusion principle? (**b**) Does either configuration violate Hund's rule? (**c**) In the absence of an external magnetic field, can we say that one electron configuration has a lower energy than the other? If so, which one has the lowest energy?



6.70 An experiment called the Stern–Gerlach experiment helped establish the existence of electron spin. In this experiment, a beam of silver atoms is passed through a magnetic field, which deflects half of the silver atoms in one direction and half in the opposite direction. The separation between the two beams increases as the strength of the magnetic field increases. (**a**) What is the electron configuration for a silver atom? (**b**) Would this experiment work for a beam of cadmium (Cd) atoms? (**c**) Would this experiment work for a beam of fluorine (F) atoms?

6.71 What is the maximum number of electrons that can occupy each of the following subshells? (**a**) 3*p*, (**b**) 5*d*, (**c**) 2*s*, (**d**) 4*f*.

6.72 What is the maximum number of electrons in an atom that can have the following quantum numbers? (**a**) $n = 3, m_l = -2$ (**b**) $n = 4, l = 3$ (**c**) $n = 5, l = 3, m_l = 2$ (**d**) $n = 4, l = 1, m_l = 0$

6.73 (**a**) What are "valence electrons"? (**b**) What are "core electrons"? (**c**) What does each box in an orbital diagram represent? (**d**) What object is represented by the half arrows in an orbital diagram? What does the direction of the arrow signify?

6.74 For each element, indicate the number of valence electrons, core electrons, and unpaired electrons in the ground state: (**a**) nitrogen, (**b**) silicon, (**c**) chlorine.

6.75 Write the condensed electron configurations for the following atoms, using the appropriate noble-gas core abbreviations: (**a**) Cs (**b**) Ni (**c**) Se (**d**) Cd (**e**) U (**f**) Pb

6.76 Write the condensed electron configurations for the following atoms and indicate how many unpaired electrons each has: (**a**) Mg (**b**) Ge (**c**) Br (**d**) V (**e**) Y (**f**) Lu

6.77 Identify the specific element that corresponds to each of the following electron configurations and indicate the number of unpaired electrons for each: (**a**) $1s^22s^2$ (**b**) $1s^22s^22p^4$ (**c**) $[Ar]4s^13d^5$ (**d**) $[Kr]5s^24d^{10}5p^4$

6.78 Identify the group of elements that corresponds to each of the following generalized electron configurations and indicate the number of unpaired electrons for each:

(**a**) $[\text{noble gas}]ns^2np^5$

(**b**) $[\text{noble gas}]ns^2(n-1)d^2$

(**c**) $[\text{noble gas}]ns^2(n-1)d^{10}np^1$

(**d**) $[\text{noble gas}]ns^2(n-2)f^6$

6.79 The following do not represent valid ground-state electron configurations for an atom either because they violate the Pauli exclusion principle or because orbitals are not filled in order of increasing energy. Indicate which of these two principles is violated in each example. (**a**) $1s^22s^23s^1$ (**b**) $[Xe]6s^25d^4$ (**c**) $[Ne]3s^23d^5$

6.80 The following electron configurations represent excited states. Identify the element and write its ground-state condensed electron configuration. (**a**) $1s^22s^22p^43s^1$ (**b**) $[Ar]4s^13d^{10}4p^25p^1$ (**c**) $[Kr]5s^24d^25p^1$

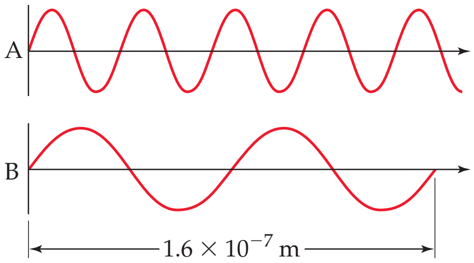
Additional Exercises

6.81 Consider the two waves shown here, which we will consider to represent two electromagnetic radiations:

(**a**) What is the wavelength of wave A? Of wave B?

(**b**) What is the frequency of wave A? Of wave B?

(**c**) Identify the regions of the electromagnetic spectrum to which waves A and B belong.



6.82 If you put 120 volts of electricity through a pickle, the pickle will smoke and start glowing orange-yellow. The light is emitted because sodium ions in the pickle become excited; their return to the ground state results in light emission. (**a**) The wavelength of this emitted light is 589 nm. Calculate its frequency. (**b**) What is the energy of 1.00 mol of these photons? (A mole of photons is called an Einstein.) (**c**) Calculate the energy gap between the excited and ground states for the sodium ion. (**d**) If you soaked the pickle for a long time in a different salt solution, such as strontium chloride, would you still observe 589-nm light emission?

6.83 Certain elements emit light of a specific wavelength when they are burned. Historically, chemists used such emission wavelengths to determine whether specific elements were present in a sample. Characteristic wavelengths for some of the elements are given in the following table:

Ag	328.1 nm	Fe	372.0 nm
Au	267.6 nm	K	404.7 nm
Ba	455.4 nm	Mg	285.2 nm
Ca	422.7 nm	Na	589.6 nm
Cu	324.8 nm	Ni	341.5 nm

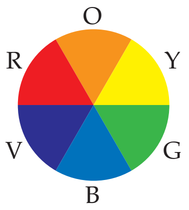
(**a**) Determine which elements emit radiation in the visible part of the spectrum. (**b**) Which element emits photons of highest energy? Of lowest energy? (**c**) When burned, a sample of an unknown substance is found to emit light of frequency $9.23 \times 10^{14}\ \mathrm{s}^{-1}$. Which of these elements is probably in the sample?

6.84 In August 2011, the Juno spacecraft was launched from Earth with the mission of orbiting Jupiter, arriving nearly five years later in July of 2016. The distance between the two planets varies depending on where each planet is in its orbit, but at the closest, the distance between Jupiter and Earth is 391 million miles. What is the minimum amount of time it takes for a transmitted signal from Juno to reach the Earth?

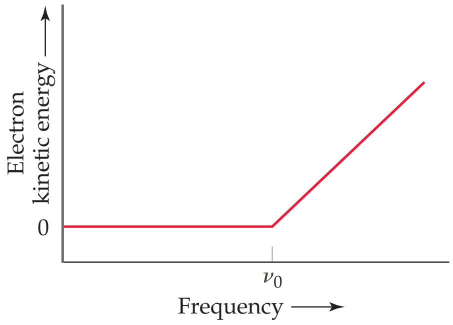
6.85 The rays of the Sun that cause tanning and burning are in the ultraviolet portion of the electromagnetic spectrum. These rays are categorized by wavelength. So-called UV-A radiation has wavelengths in the range of 320–380 nm, whereas UV-B radiation has wavelengths in the range of 290–320 nm. (**a**) Calculate the frequency of light that has a wavelength of 320 nm. (**b**) Calculate the energy of a mole of 320-nm photons. (**c**) Which are more energetic, photons of UV-A radiation or photons of UV-B radiation? (**d**) The UV-B radiation from the Sun is considered a greater cause of sunburn in humans than is UV-A radiation. Is this observation consistent with your answer to part (c)?

6.86 The watt is the derived SI unit of power, the measure of energy per unit time: $1\ \mathrm{W} = 1\ \mathrm{J/s}$. A semiconductor laser in a CD player has an output wavelength of 780 nm and a power level of 0.10 mW. How many photons strike the CD surface during the playing of a CD 69 minutes in length?

6.87 Carotenoids are yellow, orange, and red pigments synthesized by plants. The observed color of an object is not the color of light it absorbs but rather the complementary color, as described by a color wheel such as the one shown here. On this wheel, complementary colors are across from each other. (**a**) Based on this wheel, what color is absorbed most strongly if a plant is orange? (**b**) If a particular carotenoid absorbs photons at 455 nm, what is the energy of the photon?

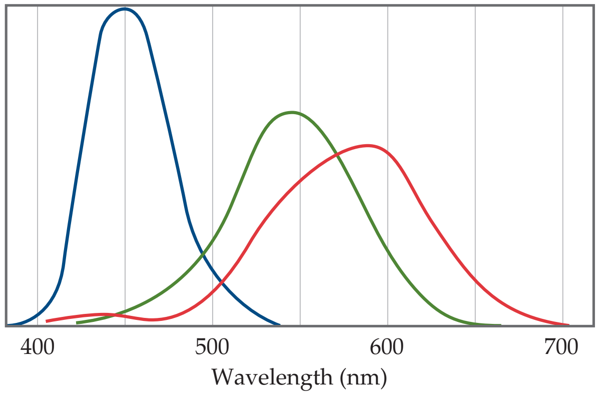


6.88 In an experiment to study the photoelectric effect, a scientist measures the kinetic energy of ejected electrons as a function of the frequency of radiation hitting a metal surface. She obtains the following plot. The point labeled "ν_0" corresponds to light with a wavelength of 542 nm. (**a**) What is the value of ν_0 in s^{-1}? (**b**) What is the value of the work function of the metal in units of kJ/mol of ejected electrons? (**c**) Note that when the frequency of the light is greater than ν_0, the plot shows a straight line with a nonzero slope. What is the slope of this line segment?



6.89 Consider a transition in which the electron of a hydrogen atom is excited from $n = 1$ to $n = \infty$. (**a**) What is the end result of this transition? (**b**) What wavelength of light must be absorbed to accomplish this process? (**c**) What will occur if light with a shorter wavelength than that in part (b) is used to excite the hydrogen atom? (**d**) How are the results of parts (b) and (c) related to the plot shown in Exercise 6.88?

6.90 The human retina has three types of receptor cones, each sensitive to a different range of wavelengths of visible light, as shown in this figure (the colors are merely to differentiate the three curves from one another; they do not indicate the actual colors represented by each curve):



(**a**) Estimate the energies of photons with wavelengths at the maximum for each type of cone. (**b**) The color of the sky is due to scattering of solar light by the molecules of the atmosphere. Lord Rayleigh was one of the first to study scattering of this kind. He showed that the amount of scattering for very small particles such as molecules is inversely proportional to the fourth power of the wavelength. Estimate the ratio of the scattering efficiency of light at the wavelength of the maximum for the "blue" cones, as compared with that for the "green" cones. (**c**) Explain why the sky appears blue even though all wavelengths of solar light are scattered by the atmosphere.

6.91 The series of emission lines of the hydrogen atom for which $n_f = 3$ is called the *Paschen series*. (**a**) Determine the region of the electromagnetic spectrum in which the lines of the Paschen series are observed. (**b**) Calculate the wavelengths of the first three lines in the Paschen series—those for which $n_i = 4, 5$, and 6.

6.92 Determine whether each of the following sets of quantum numbers for the hydrogen atom is valid. If a set is *not* valid, then indicate which of the quantum numbers has a value that is not valid:

(**a**) $n = 4, l = 1, m_l = 2, m_s = -\frac{1}{2}$
(**b**) $n = 4, l = 3, m_l = -3, m_s = +\frac{1}{2}$
(**c**) $n = 3, l = 2, m_l = -1, m_s = +\frac{1}{2}$
(**d**) $n = 5, l = 0, m_l = 0, m_s = 0$
(**e**) $n = 2, l = 2, m_l = 1, m_s = +\frac{1}{2}$

6.93 Which of the following explains why the Bohr model is applicable to a He^+ ion but not a neutral He atom? (i) The nuclear charge in He^+ is the same as that in the H atom. (ii) One electron in the He atom is attracted to the nucleus while the other is repelled from the nucleus, which complicates the model. (iii) The two electrons in the He atom repel one another, which complicates the model.

6.94 Bohr's model can be used for hydrogen-like ions—ions that have only one electron, such as He^+ and Li^{2+}. The ground-state energies of H, He^+, and Li^{2+} are tabulated as follows:

Atom or ion	**H**	**He^+**	**Li^{2+}**
Ground-state energy	$-2.18 \times 10^{-18}\ \mathrm{J}$	$-8.72 \times 10^{-18}\ \mathrm{J}$	$-1.96 \times 10^{-17}\ \mathrm{J}$

(**a**) Does the ground-state energy of the electron in these atoms/ions increase or decrease as the charge of the nucleus increases? (**b**) By examining these numbers, propose a relationship between the ground-state energy of any hydrogen-like atom or ion and the nuclear charge, Z, and use the relationship to predict the ground-state energy of the C^{5+} ion.

6.95 An electron is accelerated through an electric potential to a kinetic energy of 2.15×10^{-15} J. What is its characteristic wavelength? [*Hint:* Recall that the kinetic energy of a moving object is $E = \frac{1}{2}mv^2$, where m is the mass of the object and v is the speed of the object.]

6.96 As discussed in the A Closer Look box on "Measurement and the Uncertainty Principle," the essence of the uncertainty principle is that we can't make a measurement without disturbing the system that we are measuring. (**a**) Why can't we measure the position of a subatomic particle without disturbing it? (**b**) How is this concept related to the paradox discussed in the Closer Look box on "Schrödinger's Cat and Quantum Computing"?

6.97 For orbitals that are symmetric but not spherical, the contour representations (as in Figures 6.21 and 6.22) suggest where nodal planes exist (that is, where the electron density is zero). For example, the p_x orbital has a node wherever $x = 0$. This equation is satisfied by all points on the yz plane, so this plane is called a nodal plane of the p_x orbital. (**a**) Determine the nodal plane of the p_z orbital. (**b**) What are the two nodal planes of the d_{yz} orbital? (**c**) What are the two nodal planes of the $d_{x^2-y^2}$ orbital?

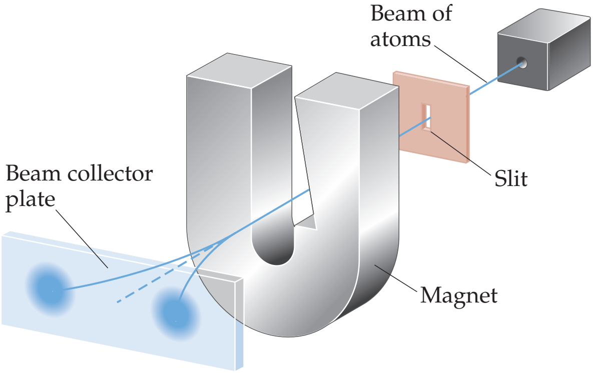
6.98 The Chemistry and Life box in Section 6.7 described the techniques called NMR and MRI. (**a**) Instruments for obtaining MRI data are typically labeled with a frequency, such as 600 MHz. In what region of the electromagnetic spectrum does a photon with this frequency belong? (**b**) What is the value of ΔE in Figure 6.25 that would correspond to the absorption of a photon of radiation with frequency 450 MHz? (**c**) When the 450 MHz photon is absorbed, does it change the spin of the electron or the proton on a hydrogen atom?

6.99 Suppose that the spin quantum number, m_s, could have *three* allowed values instead of two. How would this affect the number of elements in the first four rows of the periodic table?

6.100 Using the periodic table as a guide, write the condensed electron configuration and determine the number of unpaired electrons for the ground state of (**a**) Br, (**b**) Ga, (**c**) Hf, (**d**) Sb, (**e**) Bi, (**f**) Sg.

6.101 Scientists have speculated that element 126 might have a moderate stability, allowing it to be synthesized and characterized. Predict what the condensed electron configuration of this element might be.

6.102 In the experiment shown schematically below, a beam of neutral atoms is passed through a magnetic field. Atoms that have unpaired electrons are deflected in different directions in the magnetic field depending on the value of the electron spin quantum number. In the experiment illustrated, we envision that a beam of hydrogen atoms splits into two beams. (**a**) What is the significance of the observation that the single beam splits into two beams? (**b**) What do you think would happen if the strength of the magnet were increased? (**c**) What do you think would happen if the beam of hydrogen atoms were replaced with a beam of helium atoms? Why? (**d**) The relevant experiment was first performed by Otto Stern and Walter Gerlach in 1921. They used a beam of Ag atoms in the experiment. By considering the electron configuration of a silver atom, explain why the single beam splits into two beams.



6.103 Microwave ovens use microwave radiation to heat food. The energy of the microwaves is absorbed by water molecules in food and then transferred to other components of the food. (**a**) Suppose that the microwave radiation has a wavelength of 11.2 cm. How many photons are required to heat 200 mL of coffee from 23 to 60 °C? (**b**) Suppose the microwave's power is 900 W (1 watt = 1 joule/s). How long would you have to heat the coffee in part (a)?

6.104 The stratospheric ozone (O_3) layer helps to protect us from harmful ultraviolet radiation. It does so by absorbing ultraviolet light and falling apart into an O_2 molecule and an oxygen atom, a process known as photodissociation.

$$O_3(g) \longrightarrow O_2(g) + O(g)$$

Use the data in Appendix C to calculate the enthalpy change for this reaction. What is the maximum wavelength a photon can have if it is to possess sufficient energy to cause this dissociation? In what portion of the spectrum does this wavelength occur?

Design an Experiment

In this chapter, we have learned about the *photoelectric effect* and its impact on the formulation of light as photons. We have also seen that some anomalous electron configurations of the elements are particularly favorable if each atom has one or more half-filled shell, such as the case for the Cr atom with its $[Ar]4s^13d^5$ electron configuration. Let's suppose it is hypothesized that more energy is required to remove an electron from a metal that has atoms with one or more half-filled shells than from those that do not. (**a**) Design a series of experiments involving the photoelectric effect that would test the hypothesis.(**b**) What experimental apparatus would be needed to test the hypothesis? It's not necessary that you name actual equipment but rather that you imagine how the apparatus would work—think in terms of the types of measurements that would be needed and what capability you would need in your apparatus. (**c**) Describe the type of data you would collect and how you would analyze the data to see whether the hypothesis were correct. (**d**) Could your experiments be extended to test the hypothesis for other parts of the periodic table, such as the lanthanide or actinide elements?

7

PERIODIC PROPERTIES OF THE ELEMENTS

▲ One form of the element carbon is diamond.

The periodic table is a powerful tool for understanding and predicting the physical and chemical properties of elements. Typically, elements share common characteristics with neighbors that occupy the same column of the periodic table. Sodium, potassium, and rubidium are soft metals that react violently when they come in contact with water. Neon, argon, and krypton are colorless, chemically nonreactive gases. Copper, silver, and gold are highly conductive metals that react slowly, if at all, with air and water.

In Chapter 6 we learned that elements in the same column of the periodic table contain the same number of electrons in their **valence orbitals**—the occupied orbitals that hold the electrons involved in bonding. In this chapter, we explore several fundamental characteristics of elements. We see how these characteristics change as we move across a row or down a column of the periodic table, which in turn helps us rationalize and predict the physical and chemical properties of the elements.

WHAT'S AHEAD

7.1 ▶ Development of the Periodic Table Learn about the discovery and key moments in the development of the periodic table.

7.2 ▶ Effective Nuclear Charge Understand the concept of *effective nuclear charge*, the nuclear charge an electron in an atom experiences that is reduced by the intervening electrons, and how it varies throughout the periodic table.

7.3 ▶ Sizes of Atoms and Ions Explore the relative sizes of atoms and ions, both of which follow trends that are related to their placement in the periodic table and the trends in effective nuclear charge.

7.4 ▶ Ionization Energy and Electron Affinity Learn that *ionization energy* is the energy required to remove one or more electrons from an atom. The periodic trends in ionization energy depend on variations in effective nuclear charge and atomic radii. Learn that *electron affinity* is the energy released when an electron is added to an atom and understand its periodic trends.

7.5 ▶ Metals, Nonmetals, and Metalloids Differentiate the physical and chemical properties of metals from those of nonmetals. The differences in properties arise from the fundamental characteristics of atoms, particularly ionization energy. Metalloids display properties that are intermediate between those of metals and those of nonmetals.

7.6 ▶ Trends for Group 1A and Group 2A Metals Examine some periodic trends in the chemical and physical properties of metals belonging to groups 1A and 2A.

7.7 ▶ Trends for Selected Nonmetals Investigate some of the periodic trends in the chemical and physical properties of hydrogen and the elements in groups 6A, 7A, and 8A.

7.1 | Development of the Periodic Table

Learning Objective

When you finish Section 7.1, you should be able to:

- Describe how the periodic table was developed and is used to organize the chemical elements.

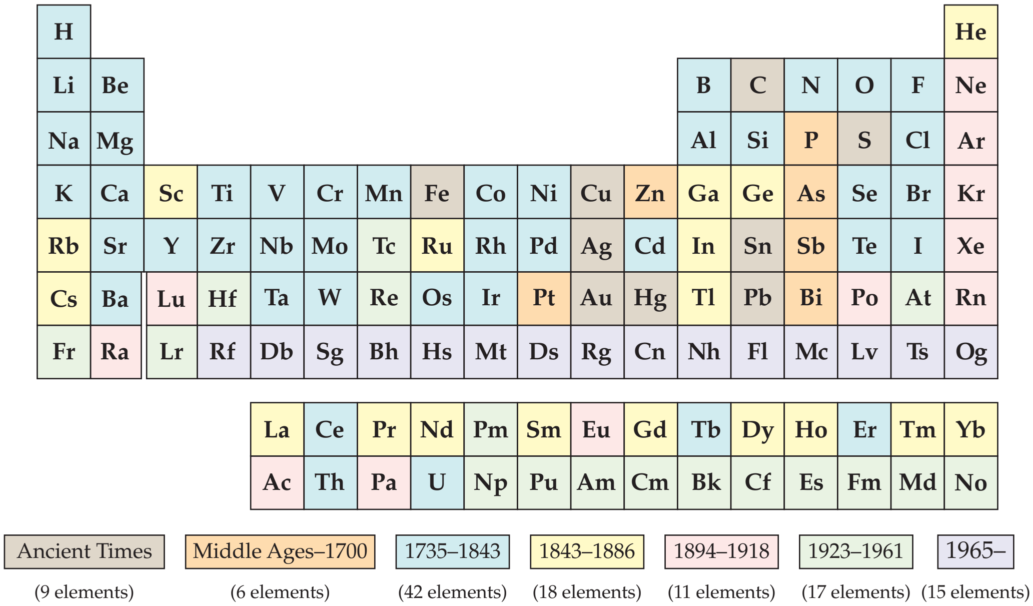
The periodic table of the elements is the defining framework for understanding the properties and chemistry of the elements. Elements in the same column in the periodic table have similar properties; and elements in the same row have trends that can be understood by considering the concepts we explore in this chapter.

The discovery of chemical elements has been ongoing since ancient times (**Figure 7.1**). Certain elements, such as gold (Au), appear in nature in elemental form and were thus discovered thousands of years ago. In contrast, some elements, such as technetium (Tc), are radioactive and intrinsically unstable. We know about them only because of technology developed during the twentieth century.

The majority of elements readily form compounds, so they are *not* found in nature in their elemental form. For centuries, therefore, scientists were unaware of their existence. During the early nineteenth century, advances in chemistry made it easier to isolate elements from their compounds. As a result, the number of known elements more than doubled from 31 in 1800 to 63 by 1865.

As the number of known elements increased, scientists began classifying them. In 1869, Dmitri Mendeleev (1834–1907) in Russia and Lothar Meyer (1830–1895) in Germany published nearly identical classification schemes. Both noted that similar chemical and physical properties recur periodically when the elements are arranged in order of increasing atomic weight. Scientists at that time had no knowledge of atomic numbers. Atomic weights, however, generally increase with increasing atomic number, so both Mendeleev and Meyer fortuitously arranged the elements in nearly the proper sequence.

Although Mendeleev and Meyer came to essentially the same conclusion about the periodicity of elemental properties, Mendeleev is given credit for advancing his ideas more vigorously and stimulating new work. His insistence that elements with similar characteristics be listed in the same column forced him to leave blank spaces in his table. For example, both gallium (Ga) and germanium (Ge) were unknown to Mendeleev. He boldly predicted their existence and properties, referring to them as *eka-aluminum* ("under" aluminum) and *eka-silicon* ("under" silicon), respectively, after the elements under which they appeared in his table. When these elements were discovered, their properties closely matched those predicted by Mendeleev, as shown in **Table 7.1**.



H He

TABLE 7.1 Comparison of the Properties of Eka-Silicon Predicted by Mendeleev with the Observed Properties of Germanium

Property	Mendeleev's Predictions for Eka-Silicon (made in 1871)	Observed Properties of Germanium (discovered in 1886)
Atomic weight	72	72.59
Density (g/cm^3)	5.5	5.35
Specific heat (J/g-K)	0.305	0.309
Melting point (°C)	High	947
Color	Dark gray	Grayish white
Formula of oxide	XO_2	GeO_2
Density of oxide (g/cm^3)	4.7	4.70
Formula of chloride	XCl_4	$GeCl_4$
Boiling point of chloride (°C)	A little under 100	84

In 1913, two years after Ernest Rutherford (1871–1937) proposed the nuclear model of the atom (Section 2.2), English physicist Henry Moseley (1887–1915) developed the concept of atomic numbers. Bombarding different elements with high-energy electrons, Moseley found that each element produced X rays of a unique frequency and that the frequency generally increased as the atomic mass increased. He arranged the X-ray frequencies in order by assigning a unique whole number, called an *atomic number*, to each element. Moseley correctly identified the atomic number as the number of protons in the nucleus of the atom. (Section 2.3)

The concept of atomic number clarified some problems in the periodic table of Moseley's day, which was based on atomic weights. For example, the atomic weight of Ar (atomic number 18) is greater than that of K (atomic number 19), yet the chemical and physical properties of Ar are much more like those of Ne and Kr than like those of Na and Rb. When the elements are arranged in order of increasing atomic number, Ar and K appear in their correct places in the table. Moseley's studies also made it possible to identify "holes" in the periodic table, which led to the discovery of new elements.

Self-Assessment Exercise

SAE 7.1 Which of the following statements is/are true?

(i) Elements that are gases were generally discovered before ones that are metals.

(ii) Metallic elements that form oxides were discovered before ones that are found as pure metals.

(iii) The heaviest elements (largest atomic numbers) were discovered last.

(**a**) i only (**b**) ii only (**c**) iii only (**d**) ii and iii

7.2 | Effective Nuclear Charge

Many properties of atoms depend on electron configuration and on how strongly the outer electrons in the atoms are attracted to the nucleus. Coulomb's law tells us that the strength of the interaction between two electrical charges depends on the magnitudes of the charges and on the distance between them. (Section 2.3) Thus, the attractive force between an electron and the nucleus depends on the magnitude of the nuclear charge and on the average distance between the nucleus and the electron. The force increases as the nuclear charge increases and decreases as the electron moves farther from the nucleus.

Understanding the attraction between the electron and the nucleus in a hydrogen atom is straightforward because we have only one electron and one proton. In a many-electron atom, however, the situation is more complicated. In addition to the attraction of each electron to the nucleus, each electron experiences repulsion due to the

Learning Objectives

When you finish Section 7.2, you should be able to:

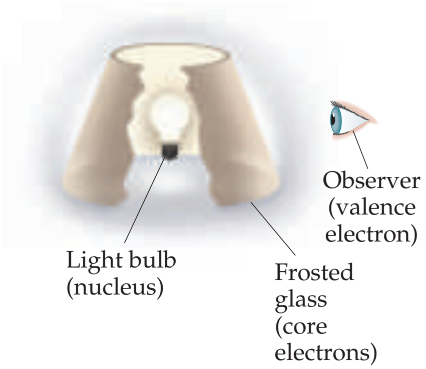
- Predict how, and understand why, effective nuclear charge varies across the periodic table.
- Calculate the effective nuclear charge for a valence electron in an atom, assuming complete screening by core electrons.

other electrons. These electron–electron repulsions cancel some of the attraction of the electron to the nucleus so that the electron experiences less attraction than it would if the other electrons weren't there. In essence, each electron in a many-electron atom is *screened* from the nucleus by the other electrons. It therefore experiences a net attraction that is *smaller* than it would experience in the absence of other electrons.

How can we account for the combination of nuclear attraction and electron repulsions for our electron of interest? The simplest way to do so is to imagine that the electron experiences a net attraction to the nucleus that is diminished (*screened*) by repulsions from the intervening electrons. We call this partially screened nuclear charge the **effective nuclear charge**, Z_{eff}. Because the full attractive force of the nucleus has been decreased by the electron repulsions, the effective nuclear charge is always *less* than the *actual* nuclear charge ($Z_{\text{eff}} < Z$). We can define the amount of screening of the nuclear charge quantitatively by using a *screening constant*, S, such that

$$Z_{\text{eff}} = Z - S \qquad [7.1]$$

where S is a positive number. For a valence electron, most of the shielding is due to the core electrons, which are much closer to the nucleus. For the valence electrons in an atom, then, *the value of S is usually close to the number of core electrons in the atom*. (Electrons in the same valence shell do not screen one another very effectively, but they do affect the value of S slightly; see "A Closer Look: Estimating Effective Nuclear Charge.")

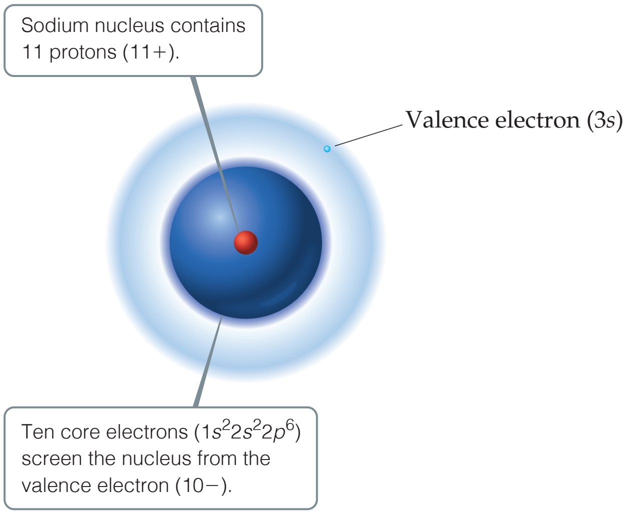


▲ **Figure 7.2 An analogy for effective nuclear charge.** We envision the nucleus as a light bulb, the core electrons as a frosted glass lampshade, and a valence electron as an observer. The amount of light seen by the observer depends on the intensity of the light bulb and the screening by the frosted glass lampshade.

To better understand the notion of effective nuclear charge, we can use an analogy of a light bulb with a frosted glass shade (**Figure 7.2**). The light bulb represents the nucleus, and the observer is the electron of interest, which is usually a valence electron. The amount of light that the electron "sees" is analogous to the amount of net nuclear attraction experienced by the electron. The other electrons in the atom, especially the core electrons, act like a frosted glass lampshade, decreasing the amount of light that gets to the observer. If the light bulb gets brighter (if Z increases) while the lampshade stays the same (while S does not change), then more light is observed. Likewise, if the lampshade gets thicker (if S increases), then less light is observed. Keep this analogy in mind as we discuss trends in effective nuclear charge.

What would you expect for the magnitude of Z_{eff} for the sodium atom? Sodium has the electron configuration $[\text{Ne}]3s^1$. The nuclear charge is $Z = 11+$, and there are 10 core electrons ($1s^22s^22p^6$), which serve as a "lampshade" to screen the nuclear charge "seen" by the $3s$ electron. Therefore, in the simplest approach, we expect S to equal 10 and the $3s$ electron to experience an effective nuclear charge of $Z_{\text{eff}} = 11 - 10 = 1+$ (**Figure 7.3**). The situation is more complicated, however, because the $3s$ electron has a small probability of being very close to the nucleus, in the region occupied by the core electrons. (Section 6.6) Thus, this electron experiences a greater net attraction than our simple

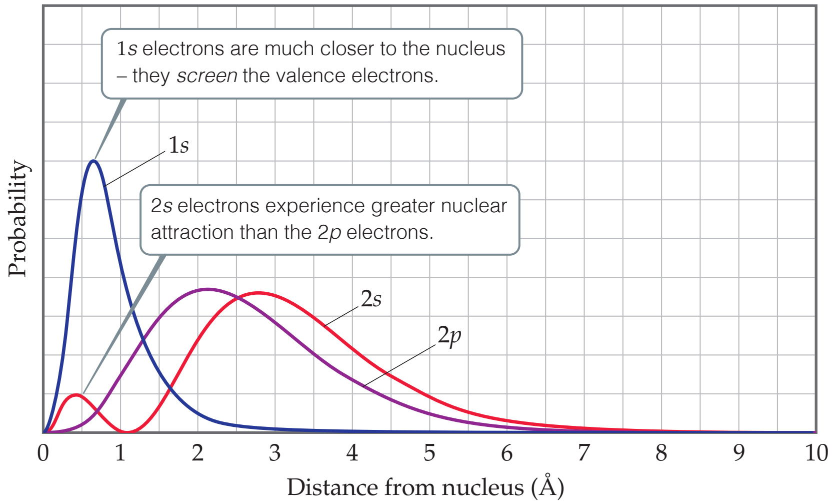
▶ **Figure 7.3 Effective nuclear charge.** The effective nuclear charge experienced by the 3*s* electron in a sodium atom depends on the 11+ charge of the nucleus and the 10− charge of the core electrons.



Sodium nucleus contains 11 protons (11+).
Valence electron (3s)
Ten core electrons ($1s^22s^22p^6$) screen the nucleus from the valence electron (10−).

Go Figure

Which electron has a higher probability of being found within 0.5 Å of the nucleus—one in a 2*s* orbital or one in a 2*p* orbital? Which orbital, 2*s* or 2*p*, will be lower in energy in a multielectron atom?



▲ **Figure 7.4** **Comparison of 1*s*, 2*s*, and 2*p* radial probability functions.**

$S = 10$ model suggests: The actual value of Z_{eff} for the 3*s* electron in Na is $Z_{\text{eff}} = 2.5+$. In other words, because there is a small probability that the 3*s* electron is close to the nucleus, the value of S in Equation 7.1 changes from 10 to 8.5.

The notion of effective nuclear charge also explains an important effect we noted in Section 6.7: For a many-electron atom, the energies of orbitals with the same n value increase with increasing l value. For example, in the carbon atom, whose electron configuration is $1s^22s^22p^2$, the energy of the 2*p* orbital ($l = 1$) is higher than that of the 2*s* orbital ($l = 0$), even though both orbitals are in the $n = 2$ shell (Figure 6.23). This difference in energies is due to the radial probability functions for the orbitals (**Figure 7.4**). We see first that the 1*s* electrons are much closer to the nucleus—they serve as an effective "lampshade" for the 2*s* and 2*p* electrons. Notice next that the 2*s* probability function has a small peak fairly close to the nucleus, whereas the 2*p* probability function does not. As a result, a 2*s* electron is not screened as much by the core orbitals as is a 2*p* electron. The greater attraction between the 2*s* electron and the nucleus leads to a lower energy for the 2*s* orbital than for the 2*p* orbital. The same reasoning explains the general trend in orbital energies ($ns < np < nd$) in many-electron atoms.

The following very important point explains many of the properties of the elements:

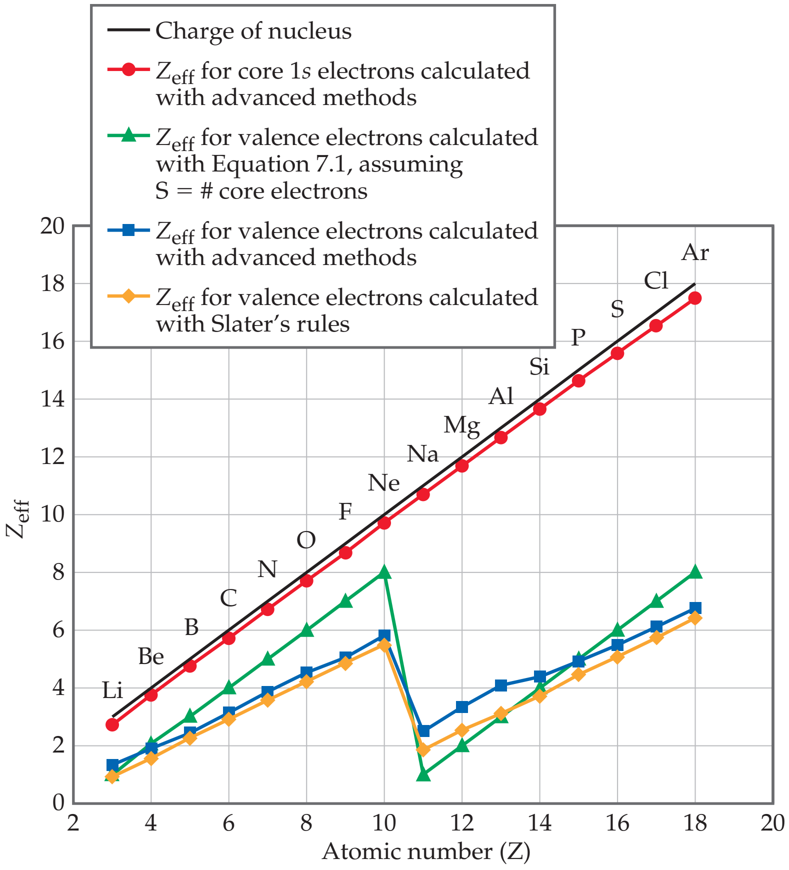
The effective nuclear charge increases from left to right across a period of the periodic table.

Although the number of core electrons stays the same across the period, the number of protons increases—in our analogy, we are increasing the brightness of the light bulb while keeping the shade the same. The valence electrons added to counterbalance the increasing nuclear charge screen one another ineffectively. Thus, Z_{eff} increases steadily in going from left to right across a row in the periodic table. For example, the two core electrons of lithium ($1s^22s^1$) screen the 2*s* valence electron from the 3+ nucleus fairly efficiently. Consequently, the valence electron experiences an effective nuclear charge of roughly $3 - 2 = 1+$. For beryllium ($1s^22s^2$), the effective nuclear charge experienced by each valence electron is larger because here the two core 1*s* electrons screen a 4+ nucleus, and each 2*s* electron only partially screens the other. Consequently, the effective nuclear charge experienced by each 2*s* electron is about $4 - 2 = 2+$.

A CLOSER LOOK Estimating Effective Nuclear Charge

To get a sense of how effective nuclear charge varies as both nuclear charge and number of electrons increase, consider **Figure 7.5**. Although the details of how the Z_{eff} values in the graph were calculated are beyond the scope of our discussion, the trends are instructive.

The effective nuclear charge felt by the outermost electrons is smaller than that felt by inner electrons because of screening by the inner electrons. In addition, the effective nuclear charge felt by the outermost electrons does not increase as steeply with increasing atomic number because the valence electrons make a small but non-negligible contribution to the screening constant S. The most striking feature associated with the Z_{eff} value for the outermost electrons is the sharp drop between the last period 2 element (Ne) and the first period 3 element (Na). This drop reflects the fact that the core electrons are much more effective than the valence electrons at screening the nuclear charge.



▲ **Figure 7.5 Variations in effective nuclear charge for period 2 and period 3 elements.** Moving from one element to the next in the periodic table, the increase in Z_{eff} felt by the innermost (1*s*) electrons (red circles) closely tracks the increase in nuclear charge Z (black line) because these electrons are not effectively screened from the nucleus by the remaining electrons. The results of several methods used to calculate Z_{eff} for valence electrons are shown in other colors.

Because Z_{eff} can be used to understand many physically measurable quantities, it is desirable to have a simple method for estimating it. The value of Z in Equation 7.1 is known exactly, so the challenge boils down to estimating the value of S. In the text, we estimated S very simply by assuming that each core electron contributes 1.00 to S and the outer electrons contribute nothing. A more accurate approach was developed by John Slater (1900–1976), and we can use his approach if we limit ourselves to elements that do not have electrons in *d* or *f* subshells.

Slater's rules are as follows: Electrons for which the principal quantum number n is larger than the value of n for the electron of interest contribute 0 to the value of S. Electrons with the same value of n as the electron of interest contribute 0.35 to the value of S. Electrons that have principal quantum number $n - 1$ contribute 0.85, while those with even smaller values of n contribute 1.00. Consider fluorine, for example, which has the ground-state electron configuration $1s^2 2s^2 2p^5$. For a valence electron in fluorine, Slater's rules tell us that $S = (0.35 \times 6) + (0.85 \times 2) = 3.8$. (Slater's rules ignore the contribution of an electron to itself in screening; therefore, we consider only six $n = 2$ electrons, not all seven). Thus, $Z_{\text{eff}} = Z - S = 9 - 3.8 = 5.2+$, which is a little lower than the simple estimate of $9 - 2 = 7+$.

Values of Z_{eff} estimated using the simple method outlined in the text, as well as those estimated with Slater's rules, are plotted in Figure 7.5. While neither of these methods exactly replicates the values of Z_{eff} obtained from more sophisticated calculations, both methods effectively capture the periodic variation in Z_{eff}. While Slater's approach is more accurate, the method outlined in the text does a reasonably good job of estimating Z_{eff} despite its simplicity. For our purposes, therefore, we can assume that the screening constant S in Equation 7.1 is roughly equal to the number of core electrons.

Related Exercises: 7.15, 7.16, 7.31, 7.32, 7.80, 7.81

Going down a column, the effective nuclear charge experienced by valence electrons changes far less than it does across a period. For example, using our simple estimate for S, we would expect the effective nuclear charge experienced by the valence electrons in lithium and sodium to be about the same, roughly $3 - 2 = 1+$ for lithium and $11 - 10 = 1+$ for sodium. In fact, however, *effective nuclear charge increases slightly as we go down a column* because the more diffuse core electron cloud is less able to screen the valence electrons from the nuclear charge. In the case of the alkali metals, Z_{eff} increases from 1.3+ for lithium, to 2.5+ for sodium, to 3.5+ for potassium.

7.3 | Sizes of Atoms and Ions

It is tempting to think of atoms as hard, spherical objects. According to the quantum-mechanical model, however, atoms do not have sharply defined boundaries at which the electron distribution becomes zero. (Section 6.5) Nevertheless, we can define atomic size in several ways, based on the distances between atoms in various situations.

Imagine a collection of argon atoms in the gas phase. When two of these atoms collide, they ricochet apart like colliding billiard balls. This ricocheting happens because the electron clouds of the colliding atoms cannot penetrate each other to any significant extent. The shortest distance separating the two nuclei during such collisions is twice the radii of the atoms. We call this radius the *nonbonding atomic radius* or the *van der Waals* radius (**Figure 7.6**).

In molecules, the attractive interaction between any two adjacent atoms is what we recognize as a chemical bond. We discuss bonding in Chapters 8 and 9. For now, we need to realize that two bonded atoms are closer together than they would be in a nonbonding collision where the atoms ricochet apart. We can therefore define an atomic radius based on the distance between the nuclei when two atoms are bonded to each other, shown as distance *d* in Figure 7.6. The **bonding atomic radius** for any atom in a molecule is equal to half of this bond distance *d*. Note from Figure 7.6 that the bonding atomic radius (also known as the *covalent radius*) is smaller than the nonbonding atomic radius. Unless otherwise noted, we mean the bonding atomic radius when we speak of the "size" of an atom.

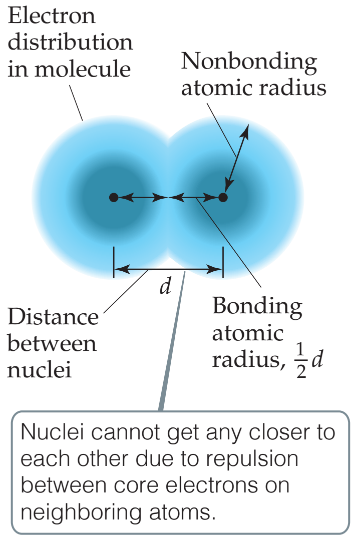
Although it is very difficult to measure the nonbonding atomic radius of an atom, scientists have developed a variety of techniques for measuring the distances separating nuclei in molecules. From observations of these distances in many molecules, each element can be assigned a bonding atomic radius. In the I_2 molecule, for example, the distance separating the nuclei is observed to be 2.66 Å, which means the bonding atomic radius of an iodine atom in I_2 is $(2.66\ \text{Å})/2 = 1.33\ \text{Å}$.* Similarly, the distance separating adjacent carbon nuclei in diamond (a three-dimensional solid network of carbon atoms) is 1.54 Å; thus, the bonding atomic radius of carbon in diamond is 0.77 Å. By using structural information on more than 30,000 substances, a consistent set of bonding atomic radii of the elements can be defined (**Figure 7.7**). For the lighter noble gases, the bonding atomic radii must be estimated because there are no known compounds of these elements.

The atomic radii in Figure 7.7 allow us to estimate bond lengths in molecules. For example, the bonding atomic radii for C and Cl are 0.76 Å and 1.02 Å, respectively. In CCl_4 the measured length of the C—Cl bond is 1.77 Å, very close to the sum $(0.76 + 1.02\ \text{Å} = 1.78\ \text{Å})$ of the bonding atomic radii of Cl and C.

Learning Objectives

When you finish Section 7.3, you should be able to:

- Calculate bond lengths in molecules using bonding atomic radii.
- Predict how atomic size varies across the periodic table.
- Explain how the radius of an atom changes upon losing electrons to form a cation or gaining electrons to form an anion.
- Write the electron configurations of ions.
- Predict relative sizes of ions in an isoelectronic series.



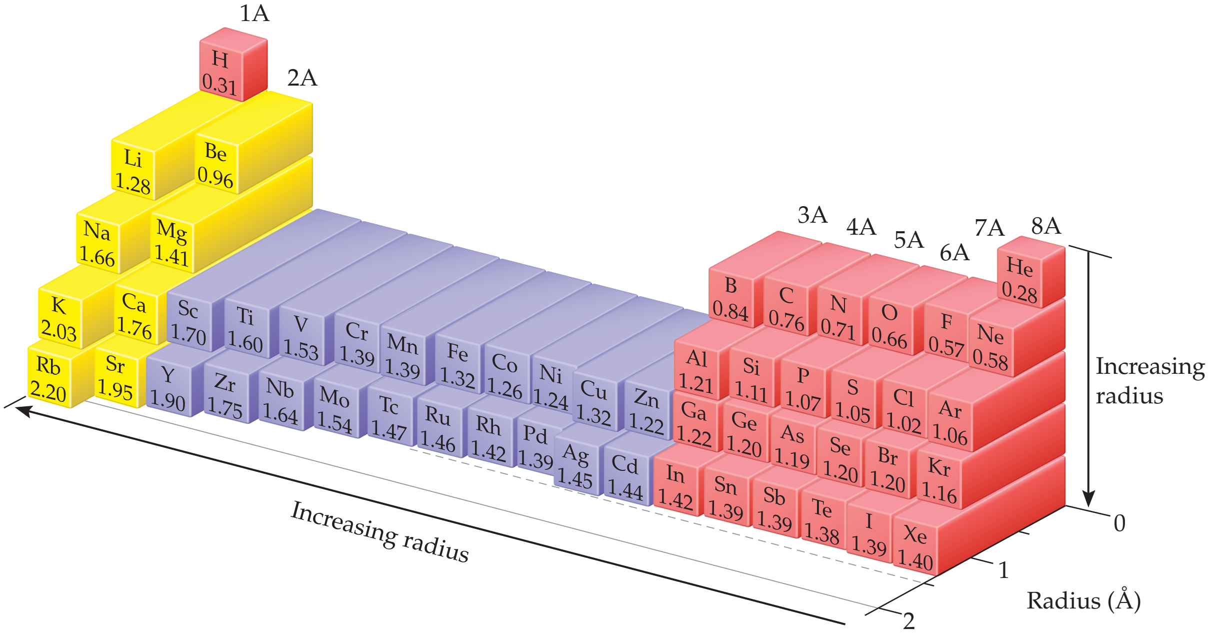
Electron distribution in molecule
Nonbonding atomic radius
d
Distance between nuclei
Bonding atomic radius, $\frac{1}{2}d$
Nuclei cannot get any closer to each other due to repulsion between core electrons on neighboring atoms.

▲ **Figure 7.6 Distinction between nonbonding and bonding atomic radii within a molecule.**

---

* Remember: The angstrom ($1\ \text{Å} = 10^{-10}\ \text{m}$) is a convenient metric unit for atomic measurements of length. It is *not* an SI unit. The most commonly used SI unit for atomic measurements is the picometer ($1\ \text{pm} = 10^{-12}\ \text{m}$; $1\ \text{Å} = 100\ \text{pm}$).

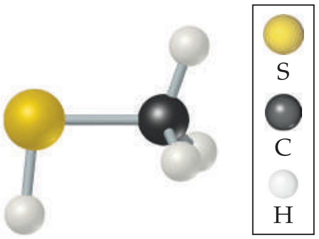
Go Figure In which part of the periodic table (top/bottom, left/right) do you find the elements with the largest radii?



▲ **Figure 7.7** Trends in bonding atomic radii for periods 1 through 5.

Sample Exercise 7.1
Bond Lengths in a Molecule

Natural gas used in home heating and cooking is odorless. Because natural gas leaks pose the danger of explosion or suffocation, various smelly substances are added to the gas to allow detection of a leak. One such substance is methyl mercaptan, CH_3SH. Use Figure 7.7 to predict the lengths of the C—S, C—H, and S—H bonds in this molecule.



Methyl mercaptan

SOLUTION

Analyze and Plan We are given three bonds and are told to use Figure 7.7 for bonding atomic radii. We will assume that each bond length is the sum of the bonding atomic radii of the two atoms involved.

Solve

$$\begin{aligned} \text{C—S bond length} &= \text{bonding atomic radius of C} \\ &\quad + \text{bonding atomic radius of S} \\ &= 0.76\ \text{Å} + 1.05\ \text{Å} = 1.81\ \text{Å} \\ \text{C—H bond length} &= 0.76\ \text{Å} + 0.31\ \text{Å} = 1.07\ \text{Å} \\ \text{S—H bond length} &= 1.05\ \text{Å} + 0.31\ \text{Å} = 1.36\ \text{Å} \end{aligned}$$

Check You can look up experimentally determined bond lengths: C—S = 1.82 Å, C—H = 1.10 Å, and S—H = 1.33 Å. (In general, the lengths of bonds involving hydrogen show larger deviations from the values predicted from bonding atomic radii than do bonds involving larger atoms.)

Comment Our estimated bond lengths are close but not exact matches to the measured bond lengths. Because they are determined by averaging over many substances, bonding atomic radii must be used with some caution in estimating bond lengths.

Practice Exercise

Using Figure 7.7, predict which is longer, the P—Br bond in PBr_3 or the As—Cl bond in $AsCl_3$.

Periodic Trends in Atomic Radii

Figure 7.7 shows two interesting trends:

1. **Within each group, bonding atomic radius tends to increase from top to bottom**. This trend results primarily from the increase in the principal quantum number (n) of the outer electrons. As we go down a column, the outer electrons have a greater probability of being farther from the nucleus, causing the atomic radius to increase.
2. **Within each period, bonding atomic radius tends to decrease from left to right** (although there are some minor exceptions, such as for Cl to Ar or As to Se). The major factor influencing this trend is the increase in Z_{eff} across a period. The increasing effective nuclear charge steadily draws the valence electrons closer to the nucleus, causing the bonding atomic radius to decrease.

Sample Exercise 7.2

Predicting Relative Sizes of Atomic Radii

Referring to the periodic table, arrange (as much as possible) the atoms B, C, Al, and Si in order of increasing size.

SOLUTION

Analyze and Plan We are given the chemical symbols for four elements and told to use their relative positions in the periodic table to predict the relative size of their atomic radii. We can use the two periodic trends described in the text to help with this problem.

Solve

B and C are in the same period, with C to the right of B. Therefore, we expect the radius of C to be smaller than that of B because radii usually decrease as we move left to right across a period.

$\text{radius C} < \text{radius B}$

Al and Si are in the same period, with Si to the right of Al.

$\text{radius Si} < \text{radius Al}$

The radius increases as we move down a group with Al and B belonging to the same group, as do C and Si.

$\text{radius B} < \text{radius Al}$

$\text{radius C} < \text{radius Si}$

Combining these comparisons, we can conclude that C has the smallest radius and Al the largest. The two periodic trends available to us do not supply enough information to determine the relative sizes of B and Si.

$\text{radius C} < \text{radius B} \sim \text{radius Si} < \text{radius Al}$

Check Referring back to Figure 7.7, we can obtain numerical values for each atomic radius that allows us to say that the radius of Si is greater than that of B.

$$\text{C}(0.76\ \text{Å}) < \text{B}\ (0.84\ \text{Å}) < \text{Si}\ (1.11\ \text{Å}) < \text{Al}\ (1.21\ \text{Å})$$

If you examine Figure 7.7 carefully, you will discover that for the *s*- and *p*-block elements the increase in radius moving one element down a column tends to be greater than the increase moving one element left across a row. There are exceptions, however.

Comment The trends we have just discussed are for the *s*- and *p*-block elements. As seen in Figure 7.7, the transition elements do not show a regular decrease moving across a period.

▶ Practice Exercise

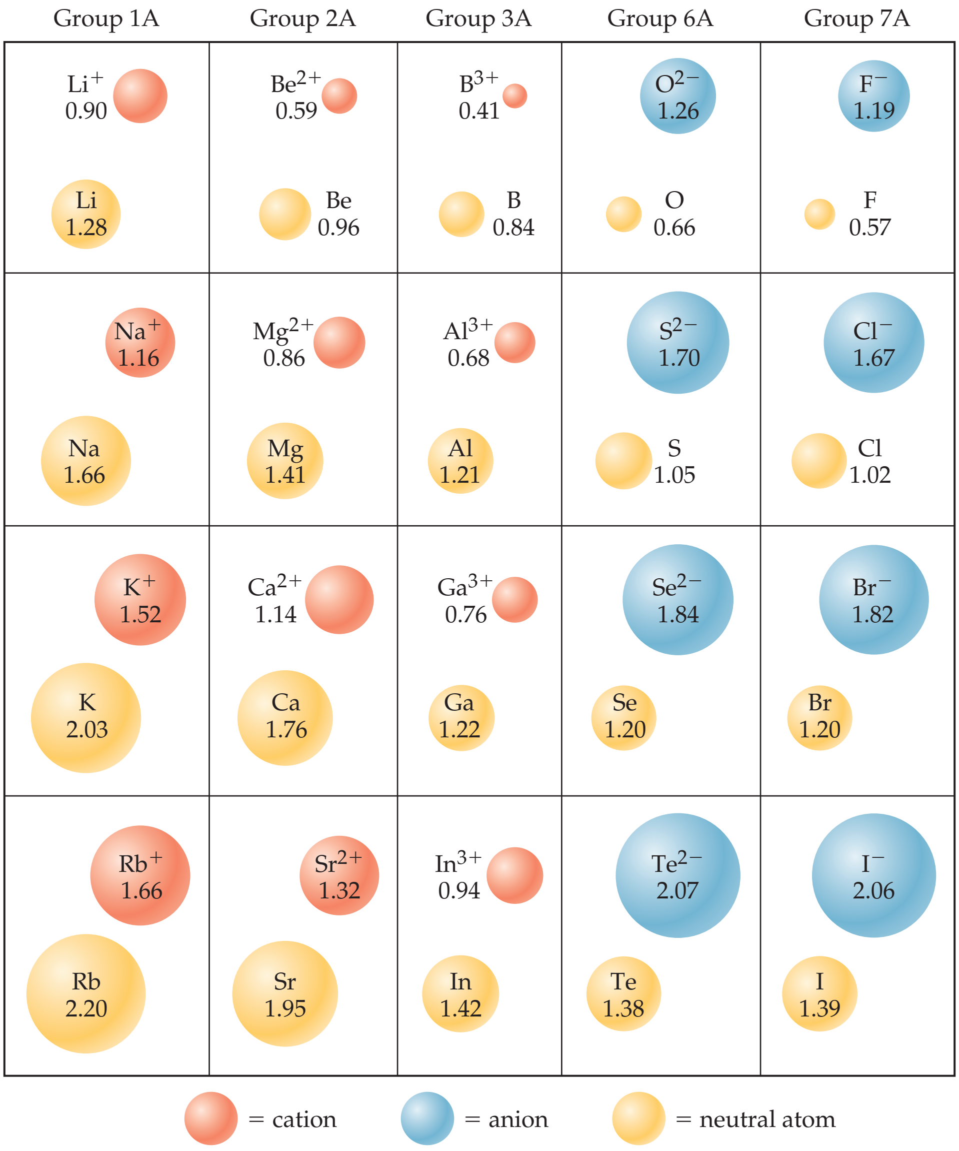
Arrange Be, C, K, and Ca in order of increasing atomic radius.

Periodic Trends in Ionic Radii

Just as bonding atomic radii can be determined from interatomic distances in molecules, ionic radii can be determined from interatomic distances in ionic compounds. Like the size of an atom, the size of an ion depends on its nuclear charge, the number of electrons it possesses, and the orbitals in which the valence electrons reside. When a cation is formed from a neutral atom, electrons are removed from the occupied atomic orbitals that are the most spatially extended from the nucleus. Also, when a cation is formed, the number of electron–electron repulsions is reduced. Therefore, *cations are smaller than*

Go Figure

How do cations of the same charge change in radius as you move down a column in the periodic table?



▲ **Figure 7.8 Cation and anion size.** Radii, in angstroms, of atoms and their ions for five groups of representative elements.

their parent atoms (Figure 7.8). The opposite is true of anions. When electrons are added to an atom to form an anion, the increased electron–electron repulsions cause the electrons to spread out more in space. Thus, *anions are larger than their parent atoms.*

For ions carrying the same charge, ionic radius increases as we move down a column in the periodic table (Figure 7.8). In other words, as the principal quantum number of the outermost occupied orbital of an ion increases, the radius of the ion increases.

Electron Configurations of Ions

When electrons are removed from an atom to form a cation, they are always removed first from the occupied orbitals having the largest principal quantum number, n. For example, when one electron is removed from a lithium atom ($1s^22s^1$), it is the $2s^1$ electron:

$$\mathrm{Li}(1s^22s^1) \Rightarrow \mathrm{Li}^+(1s^2) + e^-$$

Likewise, when two electrons are removed from Fe($[\mathrm{Ar}]4s^2 3d^6$), the $4s^2$ electrons are the ones removed:

$$\mathrm{Fe}([\mathrm{Ar}]4s^2 3d^6) \Rightarrow \mathrm{Fe}^{2+}([\mathrm{Ar}]3d^6) + 2\mathrm{e}^-$$

If an additional electron is removed, forming Fe^{3+}, it comes from a $3d$ orbital because all the orbitals with $n = 4$ are empty:

$$\mathrm{Fe}^{2+}([\mathrm{Ar}]3d^6) \Rightarrow \mathrm{Fe}^{3+}([\mathrm{Ar}]3d^5) + \mathrm{e}^-$$

It may seem odd that $4s$ electrons are removed before $3d$ electrons in forming transition-metal cations. After all, in writing electron configurations, we added the $4s$ electrons before the $3d$ electrons. In writing electron configurations for atoms, however, we are going through an imaginary process in which we move through the periodic table from one element to another. In doing so, we are adding both an electron to an orbital and a proton to the nucleus to change the identity of the element. In ionization, we *do not* reverse this process because no protons are being removed. For example, both Ca and Ti^{2+} have 20 electrons, but a Ti^{2+} ion has more protons than a Ca atom (22 vs. 20). That changes the relative energy levels of the orbitals enough that the two species have different electron configurations: Ca($[\mathrm{Ar}]4s^2$) and Ti^{2+} ($[\mathrm{Ar}]3d^2$).

If there is more than one occupied subshell for a given value of n, the electrons are first removed from the orbital with the highest value of l. For example, a tin atom loses its $5p$ electrons before it loses its $5s$ electrons:

$$\mathrm{Sn}([\mathrm{Kr}]5s^2 4d^{10} 5p^2) \Rightarrow \mathrm{Sn}^{2+}([\mathrm{Kr}]5s^2 4d^{10}) + 2\mathrm{e}^- \Rightarrow \mathrm{Sn}^{4+}([\mathrm{Kr}]4d^{10}) + 4\mathrm{e}^-$$

Electrons added to an atom to form an anion are added to the empty or partially filled orbital having the lowest value of n. For example, an electron added to a fluorine atom to form the F^- ion goes into the one remaining vacancy in the $2p$ subshell:

$$\mathrm{F}(1s^2 2s^2 2p^5) + \mathrm{e}^- \Rightarrow \mathrm{F}^-(1s^2 2s^2 2p^6)$$

An **isoelectronic series** is a group of ions that all contain the same number of electrons. For example, each ion in the isoelectronic series O^{2-}, F^-, Na^+, Mg^{2+}, and Al^{3+} has 10 electrons. In any isoelectronic series, we can list the members in order of increasing atomic number; therefore, the nuclear charge increases as we move through the series. Because the number of electrons remains constant, ionic radius decreases with increasing nuclear charge as the electrons are more strongly attracted to the nucleus:

Sample Exercise 7.3

Electron Configurations of Ions

Write the electron configurations for (**a**) Ca^{2+}, (**b**) Co^{3+}, and (**c**) S^{2-}.

SOLUTION

Analyze and Plan We are asked to write electron configurations for three ions. To do so, we first write the electron configuration of each parent atom and then remove or add electrons to form the ions. Electrons are first removed from the orbitals having the highest value of n. They are added to the empty or partially filled orbitals having the lowest value of n.

Solve

(**a**) Calcium (atomic number 20) has the electron configuration $[\mathrm{Ar}]4s^2$. To form a 2+ ion, the two $4s$ electrons must be removed, giving an ion that is isoelectronic with Ar:

$$\mathrm{Ca}^{2+}: [\mathrm{Ar}]$$

(**b**) Cobalt (atomic number 27) has the electron configuration $[\mathrm{Ar}]4s^2 3d^7$. To form a 3+ ion, three electrons must be removed. As discussed in the text, the $4s$ electrons are removed before the $3d$ electrons. Consequently, we remove the two $4s$ electrons and one of the $3d$ electrons, so the electron configuration for Co^{3+} is

$$\mathrm{Co}^{3+}: [\mathrm{Ar}]3d^6$$

(**c**) Sulfur (atomic number 16) has the electron configuration $[\mathrm{Ne}]3s^2 3p^4$. To form a 2− ion, two electrons must be added. There is room for two additional electrons in the $3p$ orbitals. Thus, the S^{2-} electron configuration is

$$\mathrm{S}^{2-}: [\mathrm{Ne}]3s^2 3p^6 = [\mathrm{Ar}]$$

Comment Remember that many of the common ions of the *s*- and *p*-block elements, such as Ca^{2+} and S^{2-}, have the same number of electrons as the closest noble gas. (Section 2.7)

Practice Exercise

Write the electron configurations for (**a**) Ga^{3+}, (**b**) Cr^{3+}, and (**c**) Br^-.

Increasing nuclear charge ⟶

8 protons 10 electrons	9 protons 10 electrons	11 protons 10 electrons	12 protons 10 electrons	13 protons 10 electrons
O^{2-}	F^-	Na^+	Mg^{2+}	Al^{3+}
1.26 Å	1.19 Å	1.16 Å	0.86 Å	0.68 Å

Decreasing ionic radius ⟶

Notice the positions and atomic numbers of these elements in the periodic table. The nonmetal anions precede the noble gas Ne in the table. The metal cations follow Ne. Oxygen, the largest ion in this isoelectronic series, has the lowest atomic number, 8. Aluminum, the smallest of these ions, has the highest atomic number, 13.

CHEMISTRY AND SUSTAINABILITY Ionic Size and Lithium-Ion Batteries

Sustainable energy sources are those that do not rely on the combustion of fossil fuels; as we know, fossil fuels will not last forever, and the CO_2 emissions they produce lead to climate change. Solar energy is in many ways the perfect energy source for built structures: It arrives on Earth every day and it is free. Harnessing solar energy while the Sun shines is possible with solar panels, but there needs to be a way to store the energy for later use. Likewise, cars, trains, and buses at present mostly use the internal combustion engine to power their motion; electric vehicles would be one solution to avoid fossil fuel combustion. Solutions for the solar energy storage problem and for powering electric vehicles include batteries. Ionic size plays a major role in determining the properties of devices, such as batteries, that rely on the movement of ions. Lithium-ion batteries, which have become common energy sources for electronic devices, such as cell phones, iPads, laptop computers, and electric vehicles, rely in part on the small size of the lithium ion for their operation.

A fully charged battery spontaneously produces an electric current and, therefore, power when its positive and negative electrodes are connected to an electrical load, such as a device to be powered. The positive electrode is called the anode, and the negative electrode is called the cathode. The materials used for the electrodes in lithium-ion batteries are under intense development. Currently, the anode material is graphite, a form of carbon, and the cathode is a transition metal oxide, often lithium cobalt oxide, $LiCoO_2$ (**Figure 7.9**). Between anode and cathode is a *separator*, a porous solid material that allows lithium ions to pass through but not electrons.

When the battery is being charged by an external source, lithium ions migrate through the separator from the cathode to the anode where they insert between the layers of carbon atoms. The ability of an ion to move through a solid increases as the size of the ion decreases and as the charge on the ion decreases. Lithium ions are smaller than most other cations, and they carry only a 1+ charge, which allows them to migrate more readily than other ions can. As an added bonus, lithium is one of the lightest elements, which is attractive for use in electric vehicles. When the battery discharges (which is when it is delivering power), the lithium ions move from anode to cathode. To maintain charge balance, electrons simultaneously migrate from anode to cathode through an external circuit, thereby producing electricity.

At the cathode, lithium ions then insert in the oxide material. Again, the small size of lithium ions is an advantage. For every lithium ion that inserts into the lithium cobalt oxide cathode, a Co^{4+} ion is reduced to a Co^{3+} ion by an electron that has traveled through the external circuit.

The ion migration and the changes in structure that result when lithium ions enter and leave the electrode materials are complicated. Furthermore, the operation of all batteries generates heat because they are not perfectly efficient. In the case of Li-ion batteries, the heating of the separator material (typically a polymer) has led to problems as the size of the batteries has been scaled larger to increase energy capacity. In a very small number of cases, overheating of Li-ion batteries has caused the batteries to catch fire.

Teams worldwide are trying to discover new cathode and anode materials that will easily accept and release lithium ions without falling apart over many repeated cycles, with an eye toward Earth-abundant elements. New separator materials that allow for faster passage of lithium ions with less heat generation are also under development. Some research groups are looking at using sodium ions instead of lithium ions because sodium is far more abundant than lithium. This makes sodium a more sustainable choice of ion, although the larger size of sodium ions poses additional challenges. In the coming years, look for continued advances in battery technology based on alkali metal ions and improvements in lithium-ion battery recycling.

Sample Exercise 7.4

Ionic Radii in an Isoelectronic Series

Arrange the ions K^+, Cl^-, Ca^{2+}, and S^{2-} in order of decreasing size.

SOLUTION

This is an isoelectronic series, with all ions having 18 electrons. In such a series, size decreases as nuclear charge (atomic number) increases. The atomic numbers of the ions are S 16, Cl 17, K 19, and Ca 20. Thus, the ions decrease in size in the order $S^{2-} > Cl^- > K^+ > Ca^{2+}$.

Practice Exercise

In the isoelectronic series Ca^{2+}, Cs^+, Y^{3+}, which ion is largest?

Self-Assessment Exercises

SAE 7.5 Use Figure 7.7 to predict which chemical bond is the longest. **(a)** H—Cl **(b)** C—C **(c)** Ge—S **(d)** B—Br

SAE 7.6 Which corner of the periodic table has the atoms with the largest bonding atomic radii? **(a)** upper left **(b)** upper right **(c)** bottom left **(d)** bottom right

SAE 7.7 Which of these ions has a different electron configuration than the others? **(a)** S^{2-} **(b)** K^+ **(c)** Ga^{3+} **(d)** Ca^{2+}

SAE 7.8 Arrange Mg^{2+}, Ca^{2+}, and Ca in order of decreasing radius.

(a) $Mg^{2+} > Ca^{2+} > Ca$
(b) $Ca > Ca^{2+} > Mg^{2+}$
(c) $Ca^{2+} > Ca > Mg^{2+}$
(d) $Ca > Mg^{2+} > Ca^{2+}$

SAE 7.9 Which ionic compound consists of ions with the largest difference in ionic size? **(a)** NaF **(b)** KCl **(c)** RbBr **(d)** CsF **(e)** CsI

SAE 7.10 Which statement about isoelectronic ions is *false*? **(a)** Na^+ is isoelectronic to Li^+. **(b)** S^{2-} is isoelectronic to Cl^-. **(c)** Anions can be isoelectronic to cations. **(d)** Trends in ionic size for isoelectronic species follow trends in effective nuclear charge.

7.4 | Ionization Energy and Electron Affinity

The ease with which electrons can be removed from an atom or ion has a major impact on chemical behavior. The **ionization energy** of an atom or ion is the minimum energy required to remove an electron from the ground state of the isolated gaseous atom or ion. We first encountered ionization in our discussion of the Bohr model of the hydrogen atom. (Section 6.3) If the electron in an H atom is excited from $n = 1$ (the ground state) to $n = \infty$, the electron is completely removed from the atom; the atom is *ionized*. The atoms of elements with low ionization energies are likely to form cations when they make compounds. Conversely, most atoms can accept electrons in the gas phase to become anions; the energy change for this process is called the **electron affinity** of the atom. Atoms of elements with low (even negative) electron affinities are likely to form anions when they make compounds.

Learning Objectives

When you finish Section 7.4, you should be able to:

- Write the chemical equations that relate to ionization energies.
- Predict periodic trends in ionization energy.
- Write the chemical equations that relate to electron affinities.
- Recognize trends in electron affinity.

In general, the *first ionization energy*, I_1, is the energy needed to remove the first electron from a neutral gas-phase atom (**Figure 7.10**). As we saw in Section 6.3 for the H atom, this corresponds to exciting the electron to $n = \infty$. For example, the first ionization energy for the sodium atom is the energy required for the process

$$Na(g) \longrightarrow Na^+(g) + e^- \qquad [7.2]$$

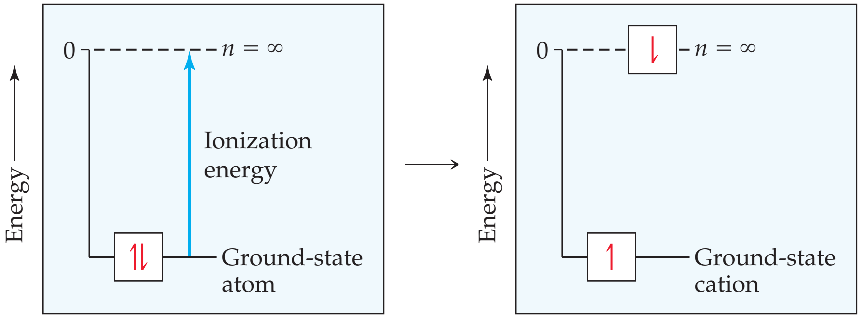

Figure 7.10 The first ionization energy (I_1) of a generic atom. I_1 is the minimum energy required to eject an electron from the indicated orbital, leaving a cation behind.

TABLE 7.2 Successive Values of Ionization Energies, I, for the Elements Sodium through Argon (kJ/mol)

Element	I_1	I_2	I_3	I_4	I_5	I_6	I_7
Na	496	4562					
Mg	738	1451	7733		(inner-shell electrons)		
Al	578	1817	2745	11,577			
Si	786	1577	3232	4356	16,091		
P	1012	1907	2914	4964	6274	21,267	
S	1000	2252	3357	4556	7004	8496	27,107
Cl	1251	2298	3822	5159	6542	9362	11,018
Ar	1521	2666	3931	5771	7238	8781	11,995

The *second ionization energy*, I_2, is the energy needed to remove the second electron, and so forth, for successive removals of additional electrons. Thus, I_2 for the sodium atom is the energy associated with the process

$$Na^{+}(g) \longrightarrow Na^{2+}(g) + e^{-} \qquad [7.3]$$

Variations in Successive Ionization Energies

The magnitude of the ionization energy indicates how much energy is required to remove an electron; the greater the ionization energy, the more difficult it is to remove an electron. **Table 7.2** presents the successive values for the ionization energies of Na through Ar. Notice that ionization energies for a given element increase as successive electrons are removed: $I_1 < I_2 < I_3$, and so forth. This trend should make sense because with each successive removal, an electron is being pulled away from an increasingly positive ion, which requires increasingly more energy.

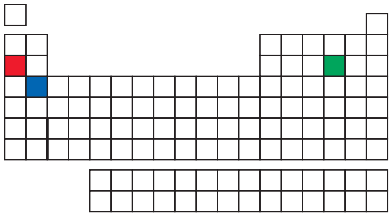
A second important feature shown in Table 7.2 is the sharp increase in ionization energy that occurs when an inner-shell electron is removed. For silicon ($1s^2 2s^2 2p^6 3s^2 3p^2$), for example, the ionization energies increase steadily from 786 to 4356 kJ/mol for the four electrons in the 3*s* and 3*p* subshells. Removal of the fifth electron, which comes from the 2*p* subshell, requires a great deal more energy: 16,091 kJ/mol. The large increase occurs because the 2*p* electron is much more likely to be found close to the nucleus than are the four $n = 3$ electrons, and, therefore, the 2*p* electron experiences a much greater effective nuclear charge than do the 3*s* and 3*p* electrons.

Every element exhibits a large increase in ionization energy when the first of its inner-shell electrons is removed. This observation supports the idea that only the outermost electrons are involved in the sharing and transfer of electrons that give rise to chemical bonding and reactions. As we show when we talk about chemical bonds in Chapters 8 and 9, the inner electrons are too tightly bound to the nucleus to be lost from the atom or even shared with another atom.

Sample Exercise 7.5

Trends in Ionization Energy

Three elements are indicated in this periodic table. Which one has the largest *second* ionization energy?



SOLUTION

Analyze and Plan The locations of the elements in the periodic table allow us to predict the electron configurations. The greatest ionization energies involve removal of core electrons. Thus, we should look first for an element with only one electron in the outermost occupied shell.

Solve The red box represents Na, which has one valence electron. The second ionization energy of this element is associated, therefore, with the removal of a core electron. The other elements indicated, S (green) and Ca (blue), have two or more valence electrons. Thus, Na should have the largest second ionization energy.

Check A chemistry handbook gives the following I_2 values: Ca, 1145 kJ/mol; S, 2252 kJ/mol; Na, 4562 kJ/mol.

▶ Practice Exercise

Which has the greater third ionization energy, Ca or S?

Periodic Trends in First Ionization Energies

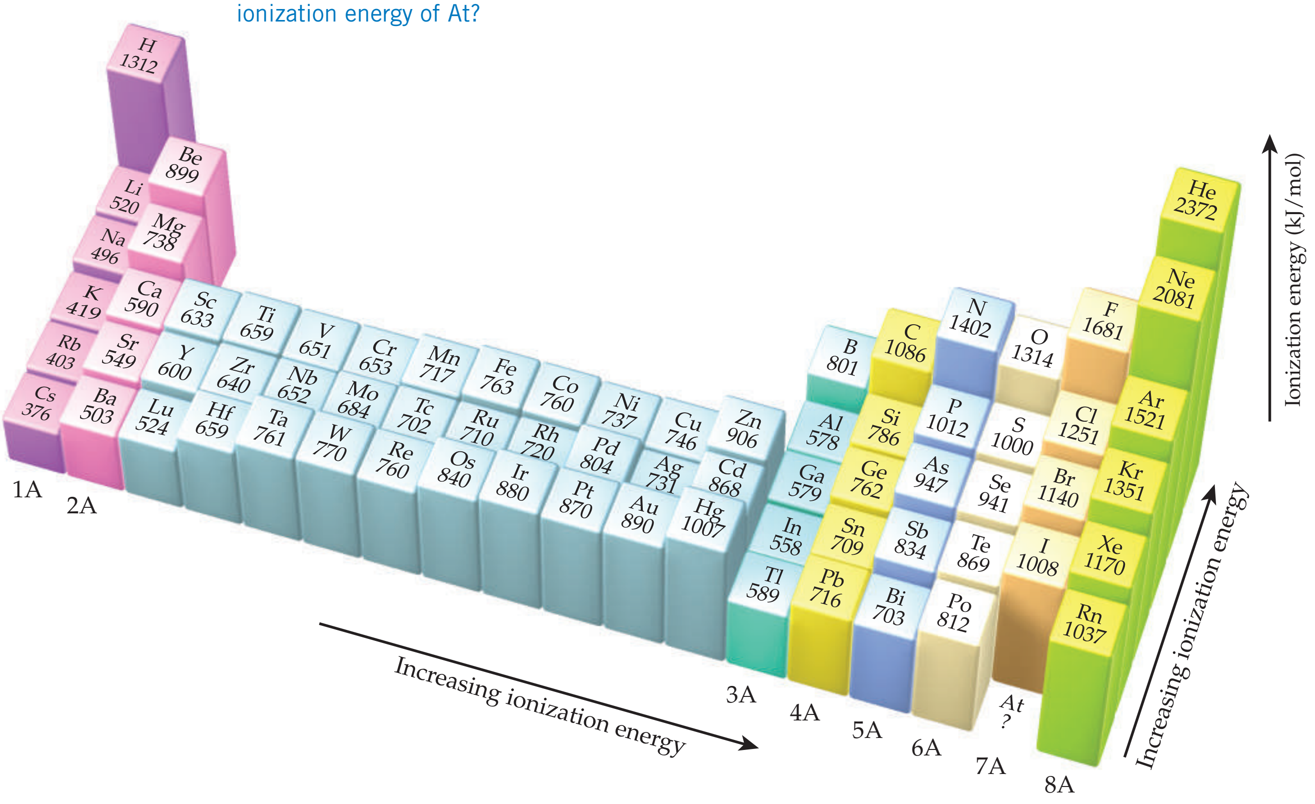
Figure 7.11 shows, for the first 54 elements, the trends we observe in first ionization energies as we move from one element to another in the periodic table. The important trends are as follows:

1. I_1 *generally increases as we move left to right across a period.* The alkali metals show the lowest ionization energy in each period, and the noble gases show the highest. There are slight irregularities in this trend that we discuss shortly.
2. I_1 *generally decreases as we move down any column in the periodic table.* For example, the ionization energies of the noble gases follow the order He > Ne > Ar > Kr > Xe.
3. *The* s- *and* p-*block elements show a larger range of* I_1 *values than do the transition-metal elements.* Generally, the ionization energies of the transition metals increase slowly from left to right in a period. The *f*-block metals (not shown in Figure 7.10) also show only a small variation in the values of I_1.

In general, smaller atoms have higher ionization energies. The same factors that influence atomic size also influence ionization energies. The energy needed to remove an electron from the outermost occupied shell depends on both the effective nuclear charge and the average distance of the electron from the nucleus. Either increasing the effective nuclear charge or decreasing the distance from the nucleus increases the attraction between the electron and the nucleus. As this attraction increases, it becomes more difficult to remove the electron, and, thus, the ionization energy increases. As we move left to right across a period, there is both an increase in effective nuclear charge and a decrease in atomic radius, causing the ionization energy to increase. As we move down a

Go Figure

The value for astatine, At, is missing in this figure. To the nearest 100 kJ/mol, what would you estimate for the first ionization energy of At?



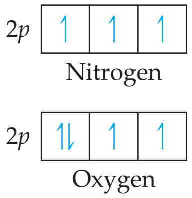
▲ **Figure 7.11 The first ionization energies of the elements in kJ/mol.**

column, the atomic radius increases, while the effective nuclear charge increases only gradually. The increase in radius dominates, so the attraction between the nucleus and the electron decreases, causing the ionization energy to decrease.

The irregularities in a given period are subtle but still readily explained. For example, the decrease in ionization energy from beryllium ([He]$2s^2$) to boron ([He]$2s^22p^1$), shown in Figure 7.11, occurs because the third valence electron of B must occupy the $2p$ subshell, which is empty for Be. Recall that the $2p$ subshell is at a higher energy than the $2s$ subshell (Figure 6.23). The slight decrease in ionization energy when moving from nitrogen ([He]$2s^22p^3$) to oxygen ([He]$2s^22p^4$) is the result of the repulsion of paired electrons in the p^4 configuration (**Figure 7.12**). Remember that according to Hund's rule, each electron in the p^3 configuration resides in a different p orbital, which minimizes the electron–electron repulsion among the three $2p$ electrons. (Section 6.8)

Go Figure

Why is it easier to remove a $2p$ electron from an oxygen atom than from a nitrogen atom?



▲ **Figure 7.12** **$2p$ orbital filling in nitrogen and oxygen.**

Sample Exercise 7.6

Periodic Trends in Ionization Energy

Referring to the periodic table, arrange the atoms Ne, Na, P, Ar, K in order of increasing first ionization energy.

SOLUTION

Analyze and Plan We are given the chemical symbols for five elements. To rank them according to increasing first ionization energy, we need to locate each element in the periodic table. We can then use their relative positions and the trends in first ionization energies to predict their order.

Solve Ionization energy increases as we move from left to right across a period and decreases as we move down a group. Because Na, P, and Ar are in the same period, we expect I_1 to vary in the order Na $<$ P $<$ Ar. Because Ne is above Ar in group 8A, we expect Ar $<$ Ne. Similarly, K is directly below Na in group 1A, and so we expect K $<$ Na.

From these observations, we conclude that the ionization energies follow the order

$$\mathrm{K} < \mathrm{Na} < \mathrm{P} < \mathrm{Ar} < \mathrm{Ne}$$

Check The values shown in Figure 7.11 confirm this prediction.

▶ **Practice Exercise**

Which has the lowest first ionization energy—B, Al, C, or Si? Which has the highest?

Electron Affinity

The first ionization energy of an atom is a measure of the energy change associated with removing an electron from the atom to form a cation. For example, the first ionization energy of Cl(g), 1251 kJ/mol, is the energy change associated with the process

$$\textit{Ionization energy:}\quad \underset{[\mathrm{Ne}]3s^23p^5}{\mathrm{Cl}(g)} \longrightarrow \underset{[\mathrm{Ne}]3s^23p^4}{\mathrm{Cl}^+(g)} + \mathrm{e}^- \qquad \Delta E = 1251\ \mathrm{kJ/mol} \qquad [7.4]$$

The positive value of the ionization energy means that energy must be put into the atom to remove the electron. *All ionization energies for atoms are positive: Energy must be absorbed to remove an electron.*

Most atoms can also gain electrons to form anions. The energy change that occurs when an electron is added to a gaseous atom is called the **electron affinity** because it measures the attraction, or *affinity*, of the atom for the added electron. For most atoms, energy is *released* when an electron is added. For example, the addition of an electron to a chlorine atom is accompanied by an energy change of −349 kJ/mol, where the negative sign indicates that energy is released during the process and that the anion is more stable than the atom. We therefore say that the electron affinity of Cl is −349 kJ/mol.*

---

*Two sign conventions are used for electron affinity. In most introductory texts, including this one, the thermodynamic sign convention is used: A negative sign indicates that addition of an electron is an exothermic process, as in the electron affinity for chlorine, −349 kJ/mol. Historically, however, electron affinity has been defined as the energy released when an electron is added to a gaseous atom or ion. Because 349 kJ/mol is released when an electron is added to Cl(g), the electron affinity by this convention would be +349 kJ/mol.

$$\begin{array}{llll} \textit{Electron affinity:} & \mathrm{Cl}(g) + e^- \longrightarrow \mathrm{Cl}^-(g) & EA = -349\ \mathrm{kJ/mol} & [7.5] \\ & [\mathrm{Ne}]3s^23p^5 \quad\quad [\mathrm{Ne}]3s^23p^6 & & \end{array}$$

Be sure you understand the difference between ionization energy and electron affinity:

- Ionization energy measures the energy change when an atom *loses* an electron.
- Electron affinity measures the energy change when an atom *gains* an electron.

The greater the attraction between an atom and an added electron, the more negative the atom's electron affinity. For some elements, such as the noble gases, the electron affinity has a positive value, meaning that the anion is higher in energy than are the separated atom and electron:

$$\begin{array}{lll} \mathrm{Ar}(g) + e^- \longrightarrow \mathrm{Ar}^-(g) & EA > 0 & [7.6] \\ [\mathrm{Ne}]3s^23p^6 \quad\quad [\mathrm{Ne}]3s^23p^64s^1 & & \end{array}$$

The fact that the electron affinity is positive means that an electron will not attach itself to an Ar atom; in other words, the Ar^- ion is unstable and does not form.

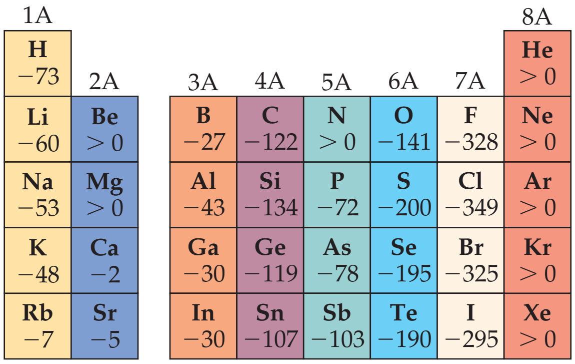
Periodic Trends in Electron Affinity

The electron affinities for the *s*- and *p*-block elements of the first five periods are shown in **Figure 7.13**. Notice that the trends are not as evident as they are for ionization energy. The halogens, which are one electron shy of a filled *p* subshell, have the most negative electron affinities. By gaining an electron, a halogen atom forms a stable anion that has a noble-gas configuration (Equation 7.5). The addition of an electron to a noble gas, however, requires that the electron reside in a higher-energy subshell that is empty in the atom (Equation 7.6). Because occupying a higher-energy subshell is energetically unfavorable, the electron affinity is highly positive. The electron affinities of Be and Mg are positive for the same reason; the added electron would reside in a previously empty *p* subshell that is higher in energy.

The electron affinities of the group 5A elements also stand out. Because these elements have half-filled *p* subshells, the added electron must be put in an orbital that is already occupied, resulting in larger electron–electron repulsions. Consequently, these elements have electron affinities that are either positive (N) or less negative than those of their neighbors to the left (P, As, Sb). Recall from Section 7.4 that there was a discontinuity in the trends in first ionization energy for the same reason.

Go Figure

Why are the electron affinities of the Group 4A elements more negative than those of the Group 5A elements?



1A	2A	3A	4A	5A	6A	7A	8A
H -73							**He** > 0
Li -60	**Be** > 0	**B** -27	**C** -122	**N** > 0	**O** -141	**F** -328	**Ne** > 0
Na -53	**Mg** > 0	**Al** -43	**Si** -134	**P** -72	**S** -200	**Cl** -349	**Ar** > 0
K -48	**Ca** -2	**Ga** -30	**Ge** -119	**As** -78	**Se** -195	**Br** -325	**Kr** > 0
Rb -7	**Sr** -5	**In** -30	**Sn** -107	**Sb** -103	**Te** -190	**I** -295	**Xe** > 0

▲ **Figure 7.13 Electron affinity in kJ/mol for selected *s*- and *p*-block elements.**

Electron affinities do not change greatly as we move down a group (Figure 7.13). With F, for instance, the added electron goes into a 2*p* orbital, for Cl a 3*p* orbital, for Br a 4*p* orbital, and so forth. As we proceed from F to I, therefore, the average distance between the added electron and the nucleus steadily increases, causing the electron–nucleus attraction to decrease. However, the orbital that holds the outermost electron is increasingly spread out, so that as we proceed from F to I, the electron–electron repulsions are also reduced. As a result, the reduction in the electron–nucleus attraction is counterbalanced by the reduction in electron–electron repulsions.

Self-Assessment Exercises

SAE 7.11 Which reaction corresponds to the *second* ionization energy of generic element A?

(a) $A(g) + e^- \longrightarrow A^-(g)$

(b) $2A(g) \longrightarrow A_2^{2+}(g) + 2e^-$

(c) $A(g) \longrightarrow A^+(g) + e^-$

(d) $A^+(g) \longrightarrow A^{2+}(g) + e^-$

(e) $A(g) \longrightarrow A^{2+}(g) + 2e^-$

SAE 7.12 Element X has successive ionization energies of 738 kJ/mol, 1451 kJ/mol, and 7733 kJ/mol, whereas element Z has successive ionization energies of 1000 kJ/mol, 2252 kJ/mol, and 3357 kJ/mol. What are the possible identities of X and Z? **(a)** X could be P because the third ionization energy is so large. Z could be Na because its ionization energies keep going up in regular intervals. **(b)** X could be Mg because its third ionization energy is so large. Z could be S because its ionization energies are large and keep going up in regular intervals. **(c)** X could be Fe because its third ionization energy is so large. Z could be H because its ionization energies keep going up in regular intervals. **(d)** X could be Na because the second and third ionization energies are so much larger than the first one. Z could be a noble gas because its ionization energies are large and keep going up in regular intervals.

Continued

SAE 7.13 A certain element X has an electron affinity that is negative. The equation for the electron affinity of X is ________ and the process is ________.

(**a**) $X(g) + e^- \longrightarrow X^-(g)$, exothermic

(**b**) $X(g) + e^- \longrightarrow X^-(g)$, endothermic

(**c**) $X(g) \longrightarrow X^+(g) + e^-$, exothermic

(**d**) $X(g) \longrightarrow X^+(g) + e^-$, endothermic

SAE 7.14 According to Figure 7.13, the electron affinities for C, N, and O are -122 kJ/mol, > 0 kJ/mol, and -141 kJ/mol, respectively. Which one of these statements about these data is correct? (**a**) The first ionization energy of N must be smaller than that of C or O. (**b**) The most stable gas-phase anion of these three elements is O^-. (**c**) The value for N is anomalous because its ground-state electron configuration is $1s^22s^22p^3$, so adding an electron to the 3*s* orbital costs a lot of energy. (**d**) The fact that the electron affinity of N is positive means that a N atom will spontaneously lose an electron to form a N^+ ion.

7.5 | Metals, Nonmetals, and Metalloids

Learning Objectives

When you finish Section 7.5, you should be able to:

- Predict whether elements are metals, nonmetals, or metalloids based on their position in the periodic table.
- Differentiate the physical and chemical properties of metals from those of nonmetals.
- Predict the products of reactions of metal and nonmetal oxides with water or acid.

Atomic radii, ionization energies, and electron affinities are properties of individual atoms. With the exception of the noble gases, however, none of the elements exist in nature as individual atoms. To get a broader understanding of the properties of elements, we must also examine periodic trends in properties of samples that involve large collections of atoms.

The elements can be broadly grouped as metals, nonmetals, and metalloids (**Figure 7.14**). (Section 2.5) Some of the distinguishing properties of metals and nonmetals are summarized in **Table 7.3**. The more an element exhibits the physical and chemical properties of metals, the greater its **metallic character**. As indicated in Figure 7.14, metallic character generally increases as we proceed down a group of the periodic table and decreases as we proceed from left to right across a period. Let's now examine the close relationships that exist between electron configurations and the properties of metals, nonmetals, and metalloids.

Go Figure

How do the periodic trends in metallic character compare to those for ionization energy?

TABLE 7.3 Characteristic Properties of Metals and Nonmetals

Metals	Nonmetals
Have a shiny luster; various colors, although most are silvery	Do not have a luster; various colors
Solids are malleable and ductile	Solids are usually brittle; some are hard, and some are soft
Good conductors of heat and electricity	Poor conductors of heat and electricity
Most metal oxides are ionic solids that are basic	Most nonmetal oxides are molecular substances that form acidic solutions
Tend to form cations in aqueous solution	Tend to form anions or oxyanions in aqueous solution

Metals

Most metallic elements exhibit the shiny luster we associate with metals (**Figure 7.15**). Metals conduct heat and electricity. In general, they are malleable (can be pounded into thin sheets) and ductile (can be drawn into wires). All are solids at room temperature except mercury (melting point = −39 °C), which is a liquid. Cesium (28.4 °C) and gallium (29.8 °C) melt at slightly above room temperature. At the other extreme, many metals melt at very high temperatures. For example, tungsten, which is used for the filaments of incandescent light bulbs, melts at 3422 °C.

Metals tend to have low ionization energies (Figure 7.11), *so they tend to form cations relatively easily.* As a result, metals tend to be oxidized (lose electrons) when they undergo chemical reactions. Among the fundamental atomic properties (radius, electron configuration, electron affinity, and so forth), first ionization energy is the best indicator of whether an element behaves as a metal or a nonmetal.

Figure 7.16 shows the typical oxidation states of ions of some of the metals and nonmetals. As noted in Section 2.7, the charge on any alkali metal ion in a compound is always 1+, and that on any alkaline earth metal is always 2+. For atoms belonging to either of these groups, the outer *s* electrons are easily lost, yielding a noble-gas electron configuration. For metals belonging to groups with partially occupied *p* orbitals (groups 3A–7A), cations are formed either by losing only the outer *p* electrons (such as Sn^{2+}) or the outer *s* and *p* electrons (such as Sn^{4+}). The charge on transition-metal ions does not follow an obvious pattern. One characteristic of the transition metals is their ability to form more than one cation. For example, compounds of Fe^{2+} and Fe^{3+} are both very common.

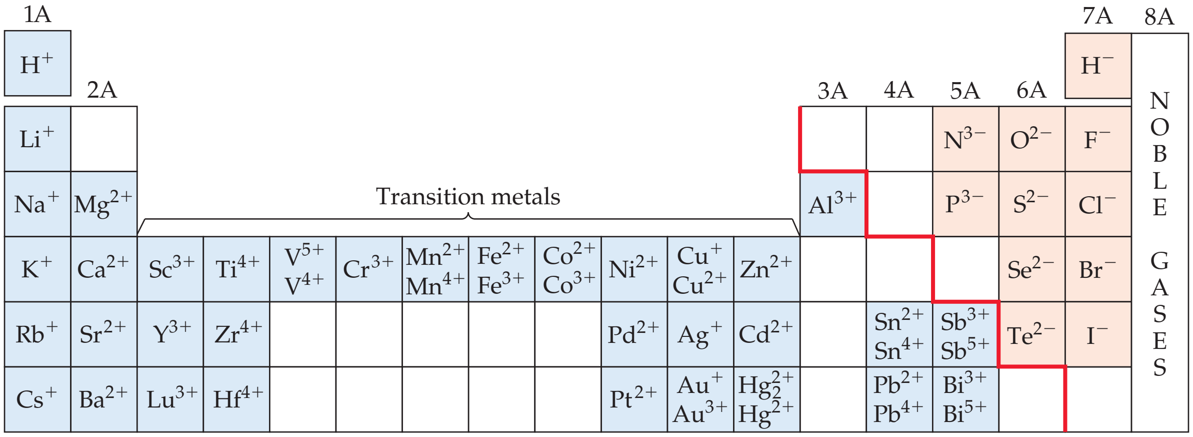
Compounds made up of a metal and a nonmetal tend to be ionic substances. For example, most metal oxides and halides are ionic solids. To illustrate, the reaction between nickel metal and oxygen produces nickel oxide, an ionic solid containing Ni^{2+} and O^{2-} ions:

$$2\,Ni(s) + O_2(g) \longrightarrow 2\,NiO(s) \qquad [7.7]$$

▲ **Figure 7.15 Metals, such as gold, are shiny, malleable, and ductile.** Gold is so malleable that one troy ounce (31.1 g) of it can be hammered into a sheet that covers more than 9 m^2.

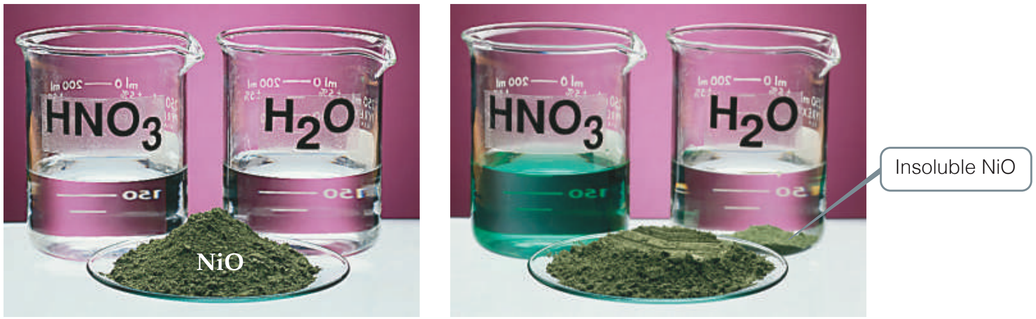
Go Figure

The red stepped line divides metals from nonmetals. How are common oxidation states divided by this line?



▲ **Figure 7.16 Common oxidation states of the elements.** Note that hydrogen exhibits both positive and negative oxidation numbers, +1 and −1.

Go Figure Would you expect NiO to dissolve in an aqueous solution of $NaNO_3$?



Nickel oxide (NiO), nitric acid (HNO_3), and water

NiO is insoluble in water but reacts with HNO_3 to give a green solution of the salt $Ni(NO_3)_2$.

▲ **Figure 7.17** **Metal oxides react with acids.** NiO does not dissolve in water but does react with nitric acid (HNO_3) to give a green solution of $Ni(NO_3)_2$.

The oxides are particularly important because of the great abundance of oxygen in our environment.

Most metal oxides are basic. Those that dissolve in water react to form metal hydroxides, as in the following examples:

$$\text{Metal oxide} + \text{water} \longrightarrow \text{metal hydroxide}$$

$$Na_2O(s) + H_2O(l) \longrightarrow 2\,NaOH(aq) \qquad [7.8]$$

$$CaO(s) + H_2O(l) \longrightarrow Ca(OH)_2(aq) \qquad [7.9]$$

The basicity of metal oxides is due to the oxide ion, which reacts with water to form hydroxide ions:

$$O^{2-}(aq) + H_2O(l) \longrightarrow 2\,OH^-(aq) \qquad [7.10]$$

Even metal oxides that are insoluble in water demonstrate their basicity by reacting with acids to form a salt plus water, as illustrated in **Figure 7.17**:

$$\text{Metal oxide} + \text{acid} \longrightarrow \text{salt} + \text{water}$$

$$NiO(s) + 2\,HNO_3(aq) \longrightarrow Ni(NO_3)_2(aq) + H_2O(l) \qquad [7.11]$$

Sample Exercise 7.7

Properties of Metal Oxides

(**a**) Would you expect scandium oxide to be a solid, liquid, or gas at room temperature?

(**b**) Write the balanced chemical equation for the reaction of scandium oxide with nitric acid.

SOLUTION

Analyze and Plan We are asked about one physical property of scandium oxide—its state at room temperature—and one chemical property—how it reacts with nitric acid.

Solve

(**a**) Because scandium oxide is the oxide of a metal, we expect it to be an ionic solid. Indeed it is, with the very high melting point of 2485 °C.

(**b**) In compounds, scandium has a 3+ charge, Sc^{3+}, and the oxide ion is O^{2-}. Consequently, the formula of scandium oxide is Sc_2O_3. Metal oxides tend to be basic, so they tend to react with acids to form a salt plus water. In this case, the salt is scandium nitrate, $Sc(NO_3)_3$:

$$Sc_2O_3(s) + 6\,HNO_3(aq) \longrightarrow 2\,Sc(NO_3)_3(aq) + 3\,H_2O(l)$$

▶ **Practice Exercise**

Write the balanced chemical equation for the reaction between copper(II) oxide and sulfuric acid.

Nonmetals

Nonmetals can be solid, liquid, or gas. They are not lustrous and generally are poor conductors of heat and electricity. Their melting points are generally lower than those of metals (although diamond, a form of carbon, is an exception; it melts at 3570 °C). Under ordinary conditions, seven nonmetals exist as diatomic molecules. Five of these are gases (H_2, N_2, O_2, F_2, and Cl_2), one is a liquid (Br_2), and one is a volatile solid (I_2). Excluding the noble gases, the remaining nonmetals are solids that can be either hard, such as diamond, or soft, such as sulfur (**Figure 7.18**).

▲ **Figure 7.18 Sulfur, known to the medieval world as "brimstone," is a nonmetal.**

Because of their relatively large, negative electron affinities, nonmetals tend to gain electrons when they react with metals. For example, the reaction of aluminum with bromine produces the ionic compound aluminum bromide:

$$2\mathrm{Al}(s) + 3\,\mathrm{Br_2}(l) \longrightarrow 2\,\mathrm{AlBr_3}(s) \qquad [7.12]$$

A nonmetal will typically gain enough electrons to fill its outermost occupied p subshell, thereby achieving a noble-gas electron configuration. For example, the bromine atom gains one electron to fill its $4p$ subshell:

$$\mathrm{Br}([\mathrm{Ar}]4s^2 3d^{10} 4p^5) + e^- \Rightarrow \mathrm{Br}^-([\mathrm{Ar}]4s^2 3d^{10} 4p^6)$$

Compounds composed entirely of nonmetals are typically molecular substances that tend to be gases, liquids, or low melting point solids at room temperature. Examples include the common hydrocarbons we use for fuel (methane, CH_4; propane, C_3H_8; octane, C_8H_{18}) and the gases HCl, NH_3, and H_2S. Many pharmaceuticals are molecules composed of C, H, N, O, and other nonmetals. For example, the molecular formula for the drug Lipitor®, which is used to treat high cholesterol, is $C_{33}H_{35}FN_2O_5$.

Most nonmetal oxides are acidic, which means that those that dissolve in water form acids:

$$\text{Nonmetal oxide} + \text{water} \longrightarrow \text{acid}$$

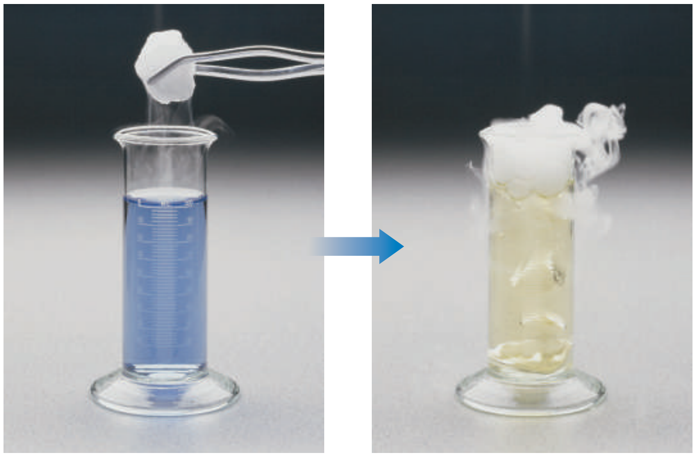
$$\mathrm{CO_2}(g) + \mathrm{H_2O}(l) \longrightarrow \mathrm{H_2CO_3}(aq) \qquad [7.13]$$

$$\mathrm{P_4O_{10}}(s) + 6\,\mathrm{H_2O}(l) \longrightarrow 4\,\mathrm{H_3PO_4}(aq) \qquad [7.14]$$

The reaction of carbon dioxide with water (**Figure 7.19**) accounts for the acidity of carbonated water and, to some extent, rainwater. Because sulfur is present in oil and coal, combustion of these common fuels produces sulfur dioxide and sulfur trioxide. These substances dissolve in water to produce acid rain, a major pollutant in many parts of the world. Like acids, most nonmetal oxides dissolve in basic solutions to form a salt plus water:

$$\text{Nonmetal oxide} + \text{base} \longrightarrow \text{salt} + \text{water}$$

$$\mathrm{CO_2}(g) + 2\,\mathrm{NaOH}(aq) \longrightarrow \mathrm{Na_2CO_3}(aq) + \mathrm{H_2O}(l) \qquad [7.15]$$



◀ **Figure 7.19 The reaction of CO_2 with water containing a bromthymol blue indicator.** Initially, the blue color tells us the water is slightly basic. When a piece of solid carbon dioxide ("dry ice") is added, the color changes to yellow, indicating an acidic solution. The mist is water droplets condensed from the air by cold CO_2 gas that sublimes before reacting.

Sample Exercise 7.8

Reactions of Nonmetal Oxides

Write a balanced chemical equation for the reaction of solid selenium dioxide, $SeO_2(s)$, with **(a)** water, **(b)** aqueous sodium hydroxide.

SOLUTION

Analyze and Plan Selenium is a nonmetal, so we need to write chemical equations for the reaction of a nonmetal oxide with water and with a base, NaOH. Nonmetal oxides are acidic, reacting with water to form an acid and with bases to form a salt and water.

Solve

(a) The reaction between selenium dioxide and water is like that between carbon dioxide and water (Equation 7.13):

$$SeO_2(s) + H_2O(l) \longrightarrow H_2SeO_3(aq)$$

(It does not matter that SeO_2 is a solid and that CO_2 is a gas under ambient conditions; the point is that both are water-soluble nonmetal oxides.)

(b) The reaction with sodium hydroxide is like that in Equation 7.15:

$$SeO_2(s) + 2\,NaOH(aq) \longrightarrow Na_2SeO_3(aq) + H_2O(l)$$

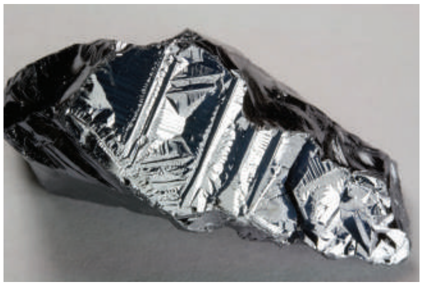
Practice Exercise

Write a balanced chemical equation for the reaction of solid tetraphosphorus hexoxide with water.

Metalloids

Metalloids have properties intermediate between those of metals and those of nonmetals. They may have some characteristic metallic properties but lack others. For example, the metalloid silicon *looks* like a metal (**Figure 7.20**), but it is brittle rather than malleable and does not conduct heat or electricity nearly as well as metals do.

Several metalloids, most notably silicon, are electrical semiconductors and are the principal elements used in integrated circuits and computer chips. One of the reasons metalloids can be used for integrated circuits is that their electrical conductivity is intermediate between that of metals and that of nonmetals. Very pure silicon is an electrical insulator, but its conductivity can be dramatically increased with the addition of specific impurities called *dopants*. This modification provides a mechanism for controlling the electrical conductivity by controlling the chemical composition. We return to this point in Chapter 12.



▲ **Figure 7.20** **Elemental silicon.**

Self-Assessment Exercises

SAE 7.15 Based on its position in the periodic table, is arsenic a **(a)** metal **(b)** nonmetal or **(c)** metalloid?

SAE 7.16 Which of these statements is true about metals? **(a)** The elements on the right side of the periodic table are metals. **(b)** Metals are brittle and fracture easily. **(c)** Metals have high electron affinities and readily form anions in aqueous solution. **(d)** Metals are good at conducting electricity but are not good at conducting heat. **(e)** None of these statements is true.

SAE 7.17 Which of the following is the expected equation for the reaction of $Fe_2O_3(s)$ with hydrochloric acid?

(a) $Fe_2O_3(s) + 6\,HCl(aq) \longrightarrow 2\,Fe(OH)_3(s) + 3\,Cl_2(g)$
(b) $Fe_2O_3(s) + 6\,HCl(aq) \longrightarrow 2\,FeCl_3(aq) + 3\,H_2O(l)$
(c) $Fe_2O_3(s) + 6\,HCl(aq) \longrightarrow 2\,FeH_3(s) + 3\,Cl_2O(aq)$
(d) $Fe_2O_3(s) + 6\,HCl(aq) \longrightarrow 2\,FeCl_2(aq) + 3\,H_2O(l)$
(e) $Fe_2O_3(s) + 6\,HCl(aq) \longrightarrow 2\,H_3FeCl_3(aq) + \frac{3}{2}\,O_2(g)$

7.6 | Trends for Group 1A and Group 2A Metals

Learning Objectives

When you finish Section 7.6, you should be able to:

- Predict the chemical reactivity of Group 1A metals.
- Predict the chemical reactivity of Group 2A metals.

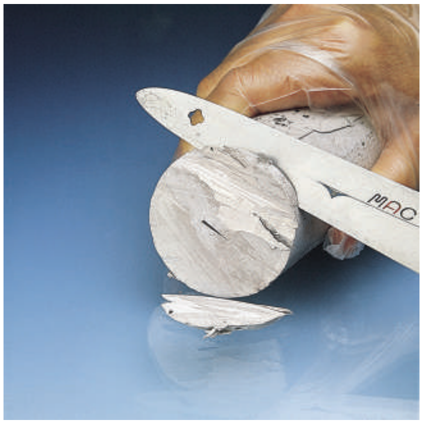
As we have seen, elements in a given group possess general similarities. However, trends also exist within each group. In this section, we use the periodic table and our knowledge of electron configurations to examine the chemistry of the **alkali metals** and **alkaline earth metals**.

Group 1A: The Alkali Metals

The alkali metals are soft metallic solids (**Figure 7.21**). All have characteristic metallic properties, such as a silvery, metallic luster, and high thermal and electrical conductivity.

TABLE 7.4 Some Properties of the Alkali Metals

Element	Electron Configuration	Melting Point (°C)	Density (g/cm^3)	Atomic Radius (Å)	I_1 (kJ/mol)
Lithium	[He]$2s^1$	181	0.53	1.28	520
Sodium	[Ne]$3s^1$	98	0.97	1.66	496
Potassium	[Ar]$4s^1$	63	0.86	2.03	419
Rubidium	[Kr]$5s^1$	39	1.53	2.20	403
Cesium	[Xe]$6s^1$	28	1.88	2.44	376



▲ **Figure 7.21** **Sodium, like the other alkali metals, is soft enough to be cut with a knife.**

The name *alkali* comes from an Arabic word meaning “ashes.” Early chemists isolated many compounds of sodium and potassium, two alkali metals, from wood ashes.

As **Table 7.4** shows, the alkali metals have low densities and melting points, and these properties vary in a fairly regular way with increasing atomic number. We see the usual trends as we move down the group, such as increasing atomic radius and decreasing first ionization energy. The alkali metal of any given period has the lowest I_1 value in the period (Figure 7.11), which reflects the relative ease with which its outer *s* electron can be removed. As a result, the alkali metals are all very reactive, readily losing one electron to form ions carrying a 1+ charge. (Section 2.7)

The alkali metals exist in nature only as compounds. Sodium and potassium are relatively abundant in Earth’s crust, in seawater, and in biological systems, always as the cations of ionic compounds. All alkali metals combine directly with most nonmetals. For example, they react with hydrogen to form hydrides and with sulfur to form sulfides:

$$2\,\mathrm{M}(s) + \mathrm{H_2}(g) \longrightarrow 2\,\mathrm{MH}(s) \qquad [7.16]$$

$$2\,\mathrm{M}(s) + \mathrm{S}(s) \longrightarrow \mathrm{M_2S}(s) \qquad [7.17]$$

where M represents any alkali metal. In hydrides of the alkali metals (LiH, NaH, and so forth), hydrogen is present as H^-, the **hydride ion**. A hydrogen atom that has *gained* an electron, the hydride ion is distinct from the hydrogen ion, H^+, formed when a hydrogen atom *loses* its electron.

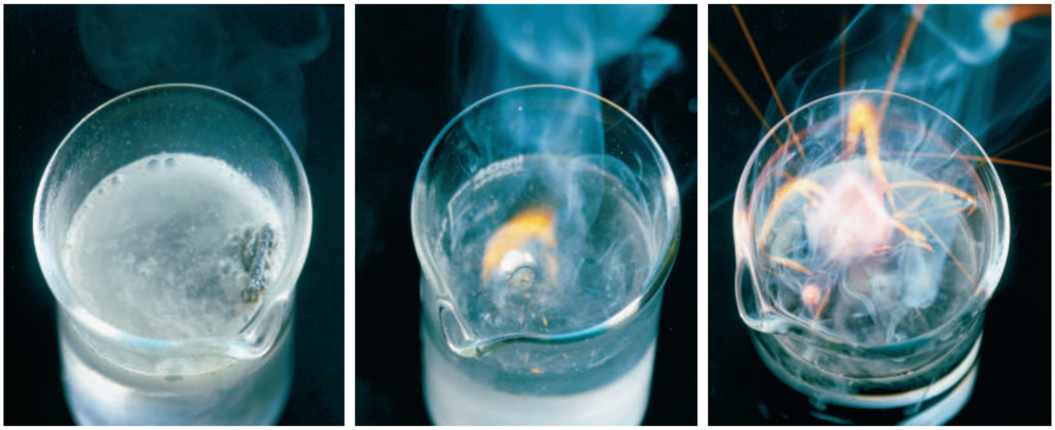
The alkali metals react vigorously with water, producing hydrogen gas and a solution of an alkali metal hydroxide:

$$2\,\mathrm{M}(s) + 2\,\mathrm{H_2O}(l) \longrightarrow 2\,\mathrm{MOH}(aq) + \mathrm{H_2}(g) \qquad [7.18]$$

These reactions are very exothermic (**Figure 7.22**). In many cases, enough heat is generated to ignite the H_2, producing a fire or sometimes even an explosion, as in the case of

Go Figure

Would you expect rubidium metal to be more or less reactive with water than potassium metal?



Li Na K

▲ **Figure 7.22** **The alkali metals react vigorously with water.**

K reacting with water. The reaction is even more violent for Rb and, especially, Cs, because their ionization energies are even lower than those of K.

Recall that the most common ion of oxygen is the oxide ion, O^{2-}. We would therefore expect that the reaction of an alkali metal with oxygen would produce the corresponding metal oxide. Indeed, reaction of Li metal with oxygen does form lithium oxide:

$$4\,\mathrm{Li}(s) + \mathrm{O_2}(g) \longrightarrow \underset{\text{lithium oxide}}{2\,\mathrm{Li_2O}(s)} \qquad [7.19]$$

When dissolved in water, Li_2O and other soluble metal oxides form hydroxide ions from the reaction of O^{2-} ions with H_2O (Equation 7.10).

The reactions of the other alkali metals with oxygen are more complex than we would anticipate. For example, when sodium reacts with oxygen, the main product is sodium *peroxide*, which contains the $O_2{}^{2-}$ ion:

$$2\,\mathrm{Na}(s) + \mathrm{O_2}(g) \longrightarrow \underset{\text{sodium peroxide}}{\mathrm{Na_2O_2}(s)} \qquad [7.20]$$

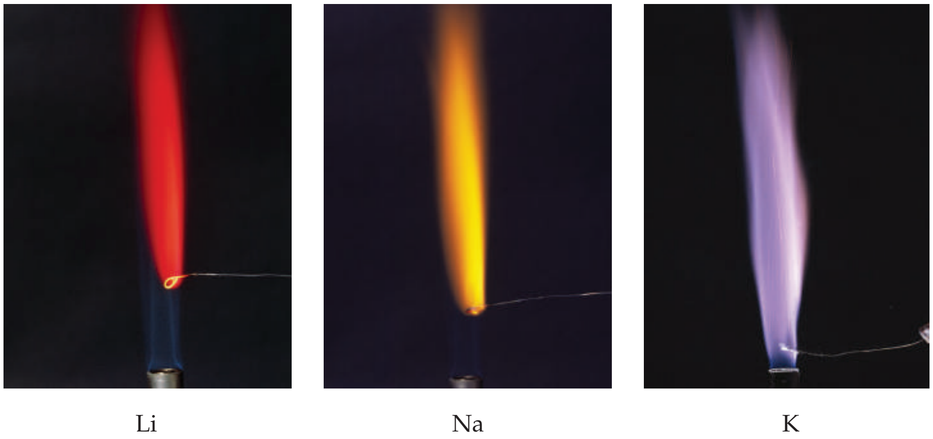
Potassium, rubidium, and cesium react with oxygen to form compounds that contain the $O_2{}^-$ ion, which is called the *superoxide ion*. For example, potassium forms potassium superoxide, KO_2:

$$\mathrm{K}(s) + \mathrm{O_2}(g) \longrightarrow \underset{\text{potassium superoxide}}{\mathrm{KO_2}(s)} \qquad [7.21]$$

The reactions in Equations 7.20 and 7.21 are somewhat unexpected; in most cases, the reaction of oxygen with a metal forms the metal oxide.

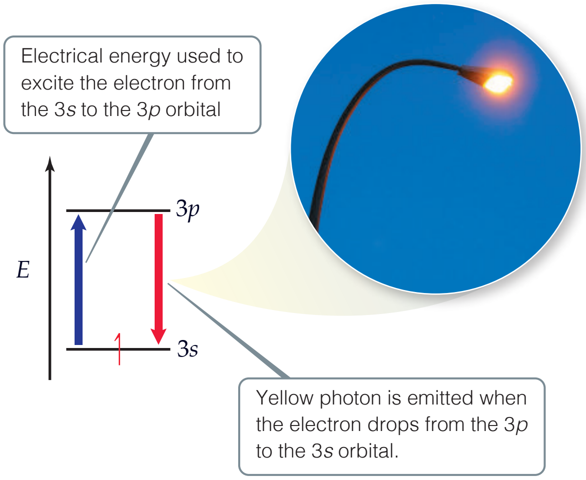
As seen from Equations 7.18–7.21, the alkali metals are extremely reactive toward water and oxygen. Because of this reactivity, the metals are usually stored submerged in a liquid hydrocarbon, such as mineral oil or kerosene.

Although alkali metal ions are colorless, each emits a characteristic color when placed in a flame (**Figure 7.23**). The ions are reduced to gaseous metal atoms in the flame. The high temperature excites the valence electron from the ground state to a higher-energy orbital, causing the atom to be in an excited state. The atom then emits energy in the form of visible light as the electron falls back into the lower-energy orbital and the atom returns to its ground state. The light emitted is at a specific wavelength for each element, just as we saw previously for the line spectra of hydrogen and neon. (Section 6.3) The characteristic yellow emission of sodium at 589 nm is the basis for sodium vapor lamps (**Figure 7.24**).



▲ **Figure 7.23** **Placed in a flame, ions of each alkali metal emit light of a characteristic wavelength.**

Go Figure If we had potassium vapor lamps, what color would they be?



Electrical energy used to excite the electron from the 3*s* to the 3*p* orbital
E
3*p*
3*s*
Yellow photon is emitted when the electron drops from the 3*p* to the 3*s* orbital.

▲ **Figure 7.24** **The characteristic yellow light of a sodium lamp.** It results from excited electrons in the high-energy 3*p* orbital falling back to the lower-energy 3*s* orbital and releasing energy in the form of light.

Sample Exercise 7.9

Reactions of an Alkali Metal

Write a balanced equation for the reaction of cesium metal with (**a**) $Cl_2(g)$, (**b**) $H_2O(l)$, (**c**) $H_2(g)$.

SOLUTION

Analyze and Plan Because cesium is an alkali metal, we expect its chemistry to be dominated by oxidation of the metal to Cs^+ ions. Further, we recognize that Cs is far down the periodic table (period 6), which means it is among the most active of all metals and probably reacts with all three substances.

Solve The reaction between Cs and Cl_2 is a simple combination reaction between a metal and a nonmetal, forming the ionic compound CsCl:

$$2\,Cs(s) + Cl_2(g) \longrightarrow 2\,CsCl(s)$$

From Equations 7.18 and 7.16, we predict the reactions of cesium with water and hydrogen to proceed as follows:

$$\begin{aligned} 2\,Cs(s) + 2\,H_2O(l) &\longrightarrow 2\,CsOH(aq) + H_2(g) \\ 2\,Cs(s) + H_2(g) &\longrightarrow 2\,CsH(s) \end{aligned}$$

All three reactions are redox reactions where cesium forms a Cs^+ ion. The Cl^-, OH^-, and H^- are all 1− ions, which means the products have 1:1 stoichiometry with Cs^+.

▶ **Practice Exercise**

Write a balanced equation for the expected reaction between potassium metal and elemental sulfur, S(*s*).

CHEMISTRY AND LIFE The Improbable Development of Lithium Drugs

Alkali metal ions tend to play an unexciting role in most chemical reactions. As noted in Section 4.2, all salts of the alkali metal ions are soluble in water, and the ions are spectators in most aqueous reactions (except for those involving the alkali metals in their elemental form, such as those in Equations 7.16–7.21). However, these ions play an important role in human physiology. Sodium and potassium ions, for example, are major components of blood plasma and intracellular fluid, respectively, with average concentrations of 0.1 *M*. These electrolytes serve as vital charge carriers in normal cellular function. In contrast, lithium ion has no known function in normal human physiology. Since the discovery of lithium in 1817, however, people have believed that salts of the element possessed almost mystical healing powers. There were even claims that lithium ions were an ingredient in ancient "fountain of youth" formulas. In 1927, C. L. Grigg began marketing a soft drink that contained lithium. The original unwieldy name of the beverage was "Bib-Label Lithiated Lemon-Lime Soda," which was soon changed to the simpler and more familiar name 7UP® (**Figure 7.25**).

In response to the Food and Drug Administration's concerns, lithium was removed from 7UP® during the early 1950s. At nearly the same time, psychiatrists discovered that lithium ions have a remarkable therapeutic effect on the mental condition called *bipolar disorder*. More than 5 million American adults each year suffer from this psychosis, undergoing severe mood swings ranging from deep depression to a manic euphoria. The lithium ion smooths these mood swings, allowing the bipolar patient to function more effectively in daily life.

▲ **Figure 7.25** **Lithium no more.** The soft drink 7UP® originally contained a lithium salt that was claimed to give the beverage healthful benefits, including "an abundance of energy, enthusiasm, a clear complexion, lustrous hair, and shining eyes!" The lithium was removed from the beverage in the early 1950s, about the time that the antipsychotic action of Li^+ was discovered.

The antipsychotic action of Li^+ was discovered by accident in the 1940s by Australian psychiatrist John Cade (1912–1980) as he was researching the use of uric acid—a component of urine—to treat manic-depressive illness. He administered the acid to manic laboratory animals in the form of its most soluble salt, lithium urate, and found that many of the manic symptoms seemed to disappear. Later studies showed that uric acid had no role in the therapeutic effects observed; rather, the Li^+ ions were responsible. Because lithium overdose can cause severe side effects in humans, including kidney failure and death, lithium salts were not approved as antipsychotic drugs for humans until 1970. Today Li^+ is usually administered orally in the form of Li_2CO_3, which is the active ingredient in prescription drugs such as Eskalith®. Lithium drugs are effective for about 70% of the bipolar patients who take it.

In this age of sophisticated drug design and biotechnology, the simple lithium ion is still the most effective treatment of this destructive psychiatric disorder. Remarkably, despite intensive research, scientists still do not fully understand the biochemical action of lithium that leads to its therapeutic effects. Because of its similarity to Na^+, Li^+ is incorporated into blood plasma, where it can affect the behavior of nerve and muscle cells. Because Li^+ has a smaller radius than Na^+ (Figure 7.8), the way Li^+ interacts with molecules in human cells is different from the way Na^+ interacts with those molecules. Other studies indicate that Li^+ alters the function of certain neurotransmitters, which might lead to its effectiveness as an antipsychotic drug.

Group 2A: The Alkaline Earth Metals

Like the alkali metals, the alkaline earth metals are all solids at room temperature and have typical metallic properties (**Table 7.5**). Compared with the alkali metals, the alkaline earth metals are harder and denser, and melt at higher temperatures.

The first ionization energies of the alkaline earth metals are low but not as low as those of the alkali metals. Consequently, the alkaline earth metals are less reactive than their alkali metal neighbors. As noted in Section 7.4, the ease with which the elements lose electrons decreases as we move left to right across a period and increases as we move down a group. Thus, beryllium and magnesium, the lightest alkaline earth metals, are the least reactive.

The trend of increasing reactivity within the group is shown by the way the alkaline earth metals behave in the presence of water. Beryllium does not react with either water or steam, even when heated red-hot. Magnesium reacts slowly with liquid water and more readily with steam:

$$Mg(s) + H_2O(g) \longrightarrow MgO(s) + H_2(g) \qquad [7.22]$$

Calcium and the elements below it react readily with water at room temperature (although more slowly than the alkali metals adjacent to them in the periodic table). The reaction between calcium and water (**Figure 7.26**), for example, is

$$Ca(s) + 2\,H_2O(l) \longrightarrow Ca(OH)_2(aq) + H_2(g) \qquad [7.23]$$

TABLE 7.5 **Some Properties of the Alkaline Earth Metals**

Element	Electron Configuration	Melting Point (°C)	Density (g/cm^3)	Atomic Radius (Å)	I_1 (kJ/mol)
Beryllium	$[He]2s^2$	1287	1.85	0.96	899
Magnesium	$[Ne]3s^2$	650	1.74	1.41	738
Calcium	$[Ar]4s^2$	842	1.55	1.76	590
Strontium	$[Kr]5s^2$	777	2.63	1.95	549
Barium	$[Xe]6s^2$	727	3.51	2.15	503

Equations 7.22 and 7.23 illustrate the dominant pattern in the reactivity of the alkaline earth elements: They tend to lose their two outer *s* electrons and form 2+ ions. For example, magnesium reacts with chlorine at room temperature to form $MgCl_2$ and burns with dazzling brilliance in air to give MgO:

$$Mg(s) + Cl_2(g) \longrightarrow MgCl_2(s) \qquad [7.24]$$

$$2\,Mg(s) + O_2(g) \longrightarrow 2\,MgO(s) \qquad [7.25]$$

In the presence of O_2, magnesium metal is protected by a thin coating of water-insoluble MgO. Thus, even though Mg is high in the activity series (Section 4.4), it can be incorporated into lightweight structural alloys used in, for example, automobile wheels. The heavier alkaline earth metals (Ca, Sr, and Ba) are even more reactive toward nonmetals than is magnesium.

The heavier alkaline earth ions give off characteristic colors when heated in a hot flame. Strontium salts produce the brilliant red color in fireworks, whereas barium salts produce the green color.

Like their neighbors sodium and potassium, magnesium and calcium are relatively abundant on Earth and in seawater and are essential for living organisms as cations in ionic compounds. Calcium is particularly important for the growth and maintenance of bones and teeth.

Self-Assessment Exercises

SAE 7.18 Which reaction(s) is/are likely to occur?

(**a**) $2\,Li(s) + H_2O(l) \longrightarrow 2\,LiH\,(s) + {}^1\!/_2\,O_2(g)$

(**b**) $2\,Li(s) + 2\,H_2O(l) \longrightarrow 2\,LiOH(aq) + H_2(g)$

(**c**) $2\,Li(s) + H_2(g) \longrightarrow 2\,LiH(s)$

(**d**) a and c

(**e**) b and c

SAE 7.19 As you go from top to bottom in group 2A of the periodic table, the elements become more reactive with water. What is the explanation for this trend? (**a**) As you go down this column in the periodic table, atomic size increases, and they are more able to insert themselves into the O—H bonds of water. (**b**) As you go down this column in the periodic table, the density of the elements increases, and so they sink faster to the bottom of a flask of water and therefore have more time to react with water. (**c**) As you go down this column in the periodic table, ionization energies decrease, so it is easier for the elements to be oxidized by water. (**d**) As you go down this column in the periodic table, ionization energies decrease, so it is easier for the elements to be reduced by water.

7.7 | Trends for Selected Nonmetals

The elements on the left side of the periodic table are metals. Progressing from the right edge of the periodic table, elements can switch from nonmetals to metalloids to metals, depending on what column and which row we are considering. Here we highlight hydrogen, which is quite unusual compared to all other elements, and groups 6A (the **chalcogens**), 7A (the **halogens**), and 8A (**the noble gases**).

Learning Objectives

When you finish Section 7.7, you should be able to:

- Describe the properties and chemical reactivity of hydrogen.
- Describe the properties and chemical reactivity of the group 6A elements.
- Describe the properties and chemical reactivity of the group 7A elements.
- Describe the properties and chemical reactivity of the group 8A elements.

Hydrogen

We have seen that the chemistry of the alkali metals is dominated by the loss of their outer ns^1 electron to form cations. The $1s^1$ electron configuration of hydrogen suggests that its chemistry should have some resemblance to that of the alkali metals. The chemistry of hydrogen is much richer and more complex than that of the alkali metals, however, mainly because the ionization energy of hydrogen, 1312 kJ/mol, is higher than that of any metal and comparable to that of oxygen. As a result, hydrogen is a nonmetal that occurs as a colorless diatomic gas, $H_2(g)$, under most conditions.

The reactivity of hydrogen with nonmetals reflects its much greater tendency to hold on to its electron relative to the alkali metals. Unlike the alkali metals, hydrogen reacts with most nonmetals to form molecular compounds in which its electron is shared with, rather than completely transferred to, the other nonmetal. For example, we have seen that sodium metal reacts vigorously with chlorine gas to produce the ionic compound sodium chloride, in which the outermost sodium electron is completely transferred to a chlorine atom (Figure 2.19):

$$\mathrm{Na}(s) + \tfrac{1}{2}\,\mathrm{Cl_2}(g) \longrightarrow \underset{\text{ionic}}{\mathrm{NaCl}(s)} \qquad \Delta H^\circ = -410.9\ \mathrm{kJ} \qquad [7.26]$$

By contrast, molecular hydrogen reacts with chlorine gas to form hydrogen chloride gas, which consists of HCl molecules:

$$\tfrac{1}{2}\,\mathrm{H_2}(g) + \tfrac{1}{2}\,\mathrm{Cl_2}(g) \longrightarrow \underset{\text{molecular}}{\mathrm{HCl}(g)} \qquad \Delta H^\circ = -92.3\ \mathrm{kJ} \qquad [7.27]$$

Hydrogen readily forms molecular compounds with other nonmetals, such as the formation of water, $H_2O(l)$; ammonia, $NH_3(g)$; and methane, $CH_4(g)$. The ability of hydrogen to form bonds with carbon is one of the most important aspects of organic chemistry, as described in later chapters.

We have seen that, particularly in the presence of water, hydrogen does readily form H^+ ions in which the hydrogen atom has lost its electron. (Section 4.3) For example, $HCl(g)$ dissolves in H_2O to form a solution of hydrochloric acid, $HCl(aq)$, in which the electron of the hydrogen atom is transferred to the chlorine atom; a solution of hydrochloric acid consists largely of $H^+(aq)$ and $Cl^-(aq)$ ions stabilized by the H_2O solvent.* Indeed, the ability of molecular compounds of hydrogen with nonmetals to form acids in water is one of the most important aspects of aqueous chemistry. We discuss the chemistry of acids and bases in detail later in the text, particularly in Chapter 16.

Finally, as is typical for nonmetals, hydrogen also has the ability to gain an electron from a metal with a low ionization energy. For example, we saw in Equation 7.16 that hydrogen reacts with active metals to form solid metal hydrides that contain the hydride ion, H^-. The fact that hydrogen can gain an electron further illustrates that it behaves much more like a nonmetal than an alkali metal.

Group 6A: The Chalcogens

As we proceed down group 6A, the **chalcogens**, there is a change from nonmetallic to metallic character (Figure 7.14). Oxygen, sulfur, and selenium are typical nonmetals. Tellurium is a metalloid, and polonium, which is radioactive and quite rare, is a metal. While oxygen is a colorless gas at room temperature, all of the other members of group 6A are solids. Some of the physical properties of the group 6A elements are listed in **Table 7.6**.

As we saw in Section 2.6, oxygen exists in two molecular forms, O_2 and O_3. Because O_2 is the more common form, people generally mean O_2 when they say "oxygen," although the name *dioxygen* is more descriptive. The O_3 form is **ozone**. The two forms of oxygen are examples of *allotropes,* defined as different forms of the same element. About 21% of dry air consists of O_2 molecules. Ozone is present in very small amounts in the

TABLE 7.6 Some Properties of the Group 6A Elements

Element	Electron Configuration	Melting Point (°C)	Density	Atomic Radius (Å)	I_1 (kJ/mol)
Oxygen	$[\mathrm{He}]2s^22p^4$	–218	1.43 g/L	0.66	1314
Sulfur	$[\mathrm{Ne}]3s^23p^4$	115	1.96 g/cm^3	1.05	1000
Selenium	$[\mathrm{Ar}]3d^{10}4s^24p^4$	221	4.82 g/cm^3	1.20	941
Tellurium	$[\mathrm{Kr}]4d^{10}5s^25p^4$	450	6.24 g/cm^3	1.38	869
Polonium	$[\mathrm{Xe}]4f^{14}5d^{10}6s^26p^4$	254	9.20 g/cm^3	1.40	812

---

*A more realistic description is one where an H^+ ion is transferred from HCl to H_2O, thereby forming Cl^- and H_3O^+. We explore this chemistry in detail in Chapter 16.

upper atmosphere and in polluted air. It is also formed from O_2 in electrical discharges, such as in lightning storms:

$$3\,O_2(g) \longrightarrow 2\,O_3(g) \qquad \Delta H^\circ = +284.6\text{ kJ} \qquad [7.28]$$

This reaction is strongly endothermic, telling us that O_3 is less stable than O_2.

Although both O_2 and O_3 are colorless and therefore do not absorb visible light, O_3 absorbs certain wavelengths of ultraviolet light that O_2 does not. Because of this difference, the presence of ozone in the upper atmosphere is beneficial, filtering out harmful UV light. Ozone and oxygen also have different chemical properties. Ozone, which has a pungent odor, is a powerful oxidizing agent. Because of this property, ozone is sometimes added to water to kill bacteria or used in low levels to help to purify air. However, the reactivity of ozone also makes its presence in polluted air near Earth's surface detrimental to human health.

Oxygen has a great tendency to attract electrons from other elements (that is, to *oxidize* them). Oxygen in combination with a metal is almost always present as the oxide ion, O^{2-}. This ion has a noble-gas configuration and is particularly stable. As shown in Figure 5.14, the formation of nonmetal oxides often is also very exothermic and thus energetically favorable.

In our discussion of the alkali metals, we noted two less common oxygen anions—the peroxide (O_2^{2-}) ion and the superoxide (O_2^{-}) ion. Compounds of these ions often react to produce an oxide and O_2:

$$2\,H_2O_2(aq) \longrightarrow 2\,H_2O(l) + O_2(g) \qquad \Delta H^\circ = -196.1\text{ kJ} \qquad [7.29]$$

For this reason, bottles of aqueous hydrogen peroxide are brown (to protect H_2O_2 from light, which can initiate its decomposition to water and oxygen) and are topped with caps that are able to release the $O_2(g)$ produced before the pressure inside becomes too great.

After oxygen, the most important member of group 6A is sulfur. This element exists in several allotropic forms, the most common and stable of which is the yellow solid having the molecular formula S_8. This molecule consists of an eight-membered ring of sulfur atoms (**Figure 7.27**). Even though solid sulfur consists of S_8 rings, we usually write it simply as S(*s*) in chemical equations to simplify the stoichiometric coefficients.

Like oxygen, sulfur has a tendency to gain electrons from other elements to form sulfides, which contain the S^{2-} ion. In fact, most sulfur in nature is present as metal sulfides. Sulfur is below oxygen in the periodic table, and the tendency of sulfur to form sulfide anions is not as great as that of oxygen to form oxide ions. As a result, the chemistry of sulfur is more complex than that of oxygen. Sulfur and its compounds (including those in coal and petroleum) can be burned in oxygen. The main product is sulfur dioxide, a major air pollutant:

$$S(s) + O_2(g) \longrightarrow SO_2(g) \qquad [7.30]$$

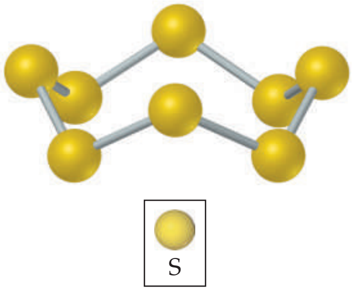
Below sulfur in group 6A is selenium, Se. This relatively rare element is essential for life in trace quantities, although it is toxic at high doses. Many allotropes of Se, including several eight-membered ring structures, resemble the S_8 ring.

The next element in the group is tellurium, Te. Its elemental structure is even more complex than that of Se, consisting of long, twisted chains of Te—Te bonds. Both Se and Te favor the −2 oxidation state, as do O and S.

From O to S to Se to Te, the elements form larger and larger molecules and become increasingly metallic. The thermal stability of group 6A compounds with hydrogen decreases down the column: $H_2O > H_2S > H_2Se > H_2Te$, with H_2O, water, being the most stable of the series.

Go Figure

Suppose it were possible to flatten the S_8 ring. What shape would you expect the flattened ring to have?



▲ **Figure 7.27 Elemental sulfur exists as the S_8 molecule.** At room temperature, this is the most common allotropic form of sulfur.

Group 7A: The Halogens

Some of the properties of the group 7A elements, the **halogens**, are listed in **Table 7.7**. Astatine, which is both extremely rare and radioactive, is omitted because many of its properties are not yet known. Even less is known about the recently discovered Tennessine (element 117).

TABLE 7.7 Some Properties of the Halogens

Element	Electron Configuration	Melting Point (°C)	Density	Atomic Radius (Å)	I_1 (kJ/mol)
Fluorine	$[He]2s^22p^5$	−220	1.69 g/L	0.57	1681
Chlorine	$[Ne]3s^23p^5$	−102	3.12 g/L	1.02	1251
Bromine	$[Ar]4s^23d^{10}4p^5$	−7.3	3.12 g/cm^3	1.20	1140
Iodine	$[Kr]5s^24d^{10}5p^5$	114	4.94 g/cm^3	1.39	1008

Unlike the group 6A elements, all of the halogens that have been characterized are nonmetals. Their melting and boiling points increase with increasing atomic number. Fluorine and chlorine are gases at room temperature, bromine is a liquid, and iodine is a solid. Each element consists of diatomic molecules: F_2, Cl_2, Br_2, and I_2 (**Figure 7.28**).

The halogens have highly negative electron affinities (Figure 7.13). Thus, it is not surprising that the chemistry of the halogens is dominated by their tendency to gain electrons from other elements to form halide ions, X^-. (In many equations, X is used to indicate any one of the halogen elements.) Fluorine and chlorine are more reactive than bromine and iodine. In fact, fluorine removes electrons from almost any substance with which it comes into contact, including water, and usually does so very exothermically, as in the following examples:

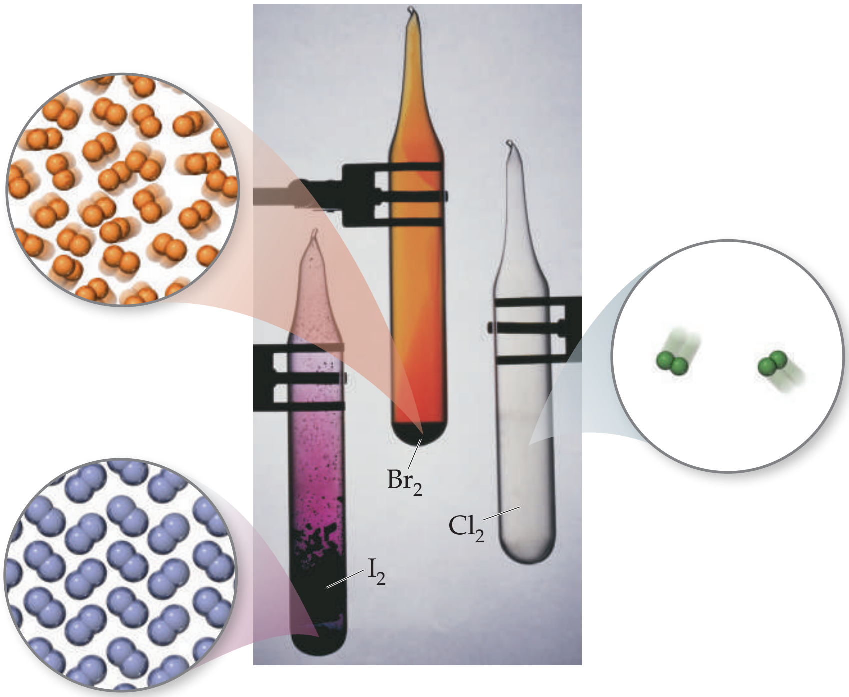
$$2\,H_2O(l) + 2\,F_2(g) \longrightarrow 4\,HF(aq) + O_2(g) \quad \Delta H = -758.9\text{ kJ} \qquad [7.31]$$

$$SiO_2(s) + 2\,F_2(g) \longrightarrow SiF_4(g) + O_2(g) \quad \Delta H = -704.0\text{ kJ} \qquad [7.32]$$

As a result, fluorine gas is difficult and dangerous to use in the laboratory, requiring specialized equipment.

Go Figure

Why are more molecules of I_2 seen in the molecular view relative to the number of Cl_2 molecules?



▲ **Figure 7.28** **The elemental halogens exist as diatomic molecules.**

Chlorine is the most industrially useful of the halogens. It is produced by a process called electrolysis, where an electrical current is used to oxidize chloride anions to molecular chlorine, Cl_2. Unlike fluorine, chlorine reacts slowly with water to form relatively stable aqueous solutions of HCl and HOCl (hypochlorous acid):

$$Cl_2(g) + H_2O(l) \longrightarrow HCl(aq) + HOCl(aq) \quad [7.33]$$

Chlorine is often added to drinking water and swimming pools because the HOCl(*aq*) that is generated serves as a disinfectant.

The halogens react directly with most metals to form ionic halides. The halogens also react with hydrogen to form gaseous hydrogen halide compounds:

$$H_2(g) + X_2 \longrightarrow 2\,HX(g) \quad [7.34]$$

All these compounds are very soluble in water and dissolve to form the hydrohalic acids. As we discussed in Section 4.3, HCl(*aq*), HBr(*aq*), and HI(*aq*) are strong acids, whereas HF(*aq*) is a weak acid.

Group 8A: The Noble Gases

The group 8A elements, known as the **noble gases**, are all nonmetals that are gases at room temperature. They are all *monatomic* (that is, they consist of single atoms rather than molecules). Some physical properties of the first six noble-gas elements are listed in **Table 7.8**. The high radioactivity of radon (Rn, atomic number 86) has limited the study of its reaction chemistry and some of its properties, and very little is known about oganesson (Og, atomic number 118), for which only a few atoms have ever been synthesized.

The noble gases have completely filled *s* and *p* subshells. All elements of group 8A have large first ionization energies, and we see the expected decrease as we move down the column. Because the noble gases possess such stable electron configurations, they are exceptionally unreactive. In fact, until the early 1960s the elements were called the *inert gases* because they were thought to be incapable of forming chemical compounds. In 1962, though, Neil Bartlett (1932–2008) at the University of British Columbia reasoned that the ionization energy of Xe might be low enough to allow it to form compounds. For this to happen, Xe would have to react with a substance that had an extremely high ability to remove electrons from other substances, such as fluorine. Bartlett synthesized the first noble-gas compound by combining Xe with the fluorine-containing compound PtF_6. Xenon also reacts directly with $F_2(g)$ to form the molecular compounds XeF_2, XeF_4, and XeF_6. Krypton has a higher I_1 value than xenon and is therefore less reactive. In fact, only a single stable compound of krypton is known, KrF_2. In 2000, Finnish scientists reported the first neutral molecule that contains argon, the HArF molecule, which is stable only at low temperatures.

TABLE 7.8 Some Properties of the Noble Gases

Element	Electron Configuration	Boiling Point (K)	Density (g/L)	Atomic Radius* (Å)	I_1 (kJ/mol)
Helium	$1s^2$	4.2	0.18	0.28	2372
Neon	$[He]2s^22p^6$	27.1	0.90	0.58	2081
Argon	$[Ne]3s^23p^6$	87.3	1.78	1.06	1521
Krypton	$[Ar]4s^23d^{10}4p^6$	120	3.75	1.16	1351
Xenon	$[Kr]5s^24d^{10}5p^6$	165	5.90	1.40	1170
Radon	$[Xe]6s^24f^{14}5d^{10}6p^6$	211	9.73	1.50	1037

*Only the heaviest of the noble-gas elements form chemical compounds. Thus, the atomic radii for the lighter noble-gas elements are estimated values.

Self-Assessment Exercises

SAE 7.20 Which statement is correct? (**a**) Group 6A elements are likely to form −1 ions. (**b**) Group 7A elements are very unreactive. (**c**) The halogens are likely to form −2 ions. (**d**) Noble gases form diatomic molecules. (**e**) None of these is correct.

SAE 7.21 Which statements is/are *true*?

(**i**) Hydrogen reacts with lithium to make lithium hydride, LiH, where H is in the −1 oxidation state.

(**ii**) Chlorine reacts with water to make hydrochloric acid and hypochlorous acid.

(**iii**) The element fluorine will react with glass (SiO_2).

(**a**) Only i is true. (**b**) Only ii is true. (**c**) Only iii is true. (**d**) Two of i, ii, and iii are true. (**e**) All of i, ii, and iii are true.

SAE 7.22 Which of the following statements about oxygen is *false*? (**a**) The most common form of oxygen is O_2. (**b**) Ozone is an allotrope of oxygen. (**c**) The most common ion formed by oxygen is the peroxide ion. (**d**) The main product when oxygen reacts with sulfur is SO_2.

Putting Concepts Together

The element bismuth (Bi, atomic number 83) is the heaviest member of group 5A. A salt of the element, bismuth subsalicylate, is the active ingredient in Pepto-Bismol®, an over-the-counter medication for gastric distress.

(**a**) Based on values presented in Figure 7.7 and Tables 7.5 and 7.6, what might you expect for the bonding atomic radius of bismuth?

(**b**) What accounts for the general increase in atomic radius going down the group 5A elements?

(**c**) Another major use of bismuth has been as an ingredient in low-melting metal alloys, such as those used in fire sprinkler systems and in typesetting. The element itself is a brittle white crystalline solid. How do these characteristics fit with the fact that bismuth is in the same periodic group with such nonmetallic elements as nitrogen and phosphorus?

(**d**) Bi_2O_3 is a basic oxide. Write a balanced chemical equation for its reaction with dilute nitric acid. If 6.77 g of Bi_2O_3 is dissolved in dilute acidic solution to make 0.500 L of solution, what is the molarity of the solution of Bi^{3+} ion?

(**e**) ^{209}Bi is the heaviest stable isotope of any element. How many protons and neutrons are present in this nucleus?

(**f**) The density of Bi at 25 °C is 9.808 g/cm^3. How many Bi atoms are present in a cube of the element that is 5.00 cm on each edge? How many moles of the element are present?

SOLUTION

(**a**) Bismuth is directly below antimony, Sb, in group 5A. Based on the observation that atomic radii increase as we go down a column, we would expect the radius of Bi to be greater than that of Sb, which is 1.39 Å. We also know that atomic radii generally decrease as we proceed from left to right in a period. Tables 7.5 and 7.6 each give an element in the same period—namely, Ba and Po. We would therefore expect that the radius of Bi is smaller than that of Ba (2.15 Å) and larger than that of Po (1.40 Å). We also see that in other periods, the difference in radius between the neighboring group 5A and group 6A elements is relatively small. We might therefore expect that the radius of Bi is slightly larger than that of Po—much closer to the radius of Po than to the radius of Ba. The tabulated value for the atomic radius on Bi is 1.48 Å, in accord with our expectations.

(**b**) The general increase in radius with increasing atomic number in the group 5A elements occurs because additional shells of electrons are being added, with corresponding increases in nuclear charge. The core electrons in each case largely screen the outermost electrons from the nucleus, so the effective nuclear charge does not vary greatly as we go to higher atomic numbers. However, the principal quantum number, *n*, of the outermost electrons steadily increases, with a corresponding increase in orbital radius.

(**c**) The contrast between the properties of bismuth and those of nitrogen and phosphorus illustrates the general rule that there is a trend toward increased metallic character as we move down in a given group. Bismuth, in fact, is a metal. The increased metallic character occurs because the outermost electrons are more readily lost in bonding, a trend that is consistent with its lower ionization energy.

(**d**) Following the procedures described in Section 4.2 for writing molecular and net ionic equations, we have the following:

Molecular equation:

$$Bi_2O_3(s) + 6\,HNO_3(aq) \longrightarrow 2\,Bi(NO_3)_3(aq) + 3\,H_2O(l)$$

Net ionic equation:

$$Bi_2O_3(s) + 6\,H^+(aq) \longrightarrow 2\,Bi^{3+}(aq) + 3\,H_2O(l)$$

In the net ionic equation, nitric acid is a strong acid and $Bi(NO_3)_3$ is a soluble salt, so we need to show only the reaction of the solid with the hydrogen ion forming the $Bi^{3+}(aq)$ ion and water. To calculate the concentration of the solution, we proceed as follows (Section 4.5):

$$\frac{6.77\ \cancel{g\ Bi_2O_3}}{0.500\ L\ soln} \times \frac{1\ \cancel{mol\ Bi_2O_3}}{466.0\ \cancel{g\ Bi_2O_3}} \times \frac{2\ mol\ Bi^{3+}}{1\ \cancel{mol\ Bi_2O_3}}$$

$$= \frac{0.0581\ mol\ Bi^{3+}}{L\ soln} = 0.0581\ M$$

(**e**) Recall that the atomic number of any element is the number of protons and electrons in a neutral atom of the element. (Section 2.3) Bismuth is element 83, so there are 83 protons in the nucleus. Because the atomic mass number is 209, there are $209 - 83 = 126$ neutrons in the nucleus.

(**f**) We can use the density and the atomic weight to determine the number of moles of Bi, and then we can use Avogadro's number to convert the result to the number of atoms. (Sections 1.4 and 3.4) The volume of the cube is $(5.00)^3\ cm^3 = 125\ cm^3$. Then we have

$$125\ \cancel{cm^3}\ \cancel{Bi} \times \frac{9.808\ \cancel{g\ Bi}}{1\ \cancel{cm^3}} \times \frac{1\ mol\ Bi}{209.0\ \cancel{g\ Bi}} = 5.87\ mol\ Bi$$

$$5.87\ \cancel{mol\ Bi} \times \frac{6.022 \times 10^{23}\ atom\ Bi}{\cancel{1\ mol\ Bi}} = 3.53 \times 10^{24}\ atoms\ Bi$$

Chapter Summary and Key Terms

DEVELOPMENT OF THE PERIODIC TABLE AND EFFECTIVE NUCLEAR CHARGE (SECTIONS 7.1 AND 7.2) The periodic table was first developed by Mendeleev and Meyer on the basis of the similarity in chemical and physical properties exhibited by certain elements. Moseley established that each element has a unique atomic number, which added more order to the periodic table.

We now know that elements in the same column of the periodic table have the same number of electrons in their **valence orbitals**. This similarity in valence electronic structure leads to the similarities among elements in the same group. Differences among elements in the same group arise because their valence orbitals are in different shells.

Many properties of atoms depend on the **effective nuclear charge**, which is the portion of the nuclear charge that an outer electron experiences after accounting for repulsions by other electrons in the atom. The core electrons are very effective in screening the outer electrons from the full charge of the nucleus, whereas electrons in the same shell do not screen each other very effectively. Because the actual nuclear charge increases as we progress through a period, the effective nuclear charge experienced by valence electrons increases as we move left to right across a period.

SIZES OF ATOMS AND IONS (SECTION 7.3) The size of an atom can be gauged by its **bonding atomic radius**, which is based on measurements of the distances separating atoms in their chemical compounds. In general, atomic radii increase down a column in the periodic table and decrease left to right across a row.

Cations are smaller than their parent atoms, whereas anions are larger than their parent atoms. For ions of the same charge, size increases going down a column of the periodic table. We can write electron configurations for ions by first writing the electron configuration of the neutral atom and then removing or adding the appropriate number of electrons. For cations, electrons are removed first from the orbitals of the neutral atom with the largest value of n. If there are two valence orbitals with the same value of n (such as $4s$ and $4p$), then the electrons are lost first from the orbital with a higher value of l (in this case, $4p$). For anions, electrons are added to orbitals in the reverse order.

An **isoelectronic series** is a series of ions that has the same number of electrons. For such a series, size decreases with increasing atomic number as the electrons are attracted more strongly to the nucleus as its positive charge increases.

IONIZATION ENERGY AND ELECTRON AFFINITY (SECTION 7.4) The first **ionization energy** of an atom is the minimum energy needed to remove an electron from the atom in the gas phase, forming a cation. The second ionization energy is the energy needed to remove a second electron from the cation, and so forth. Ionization energies show a sharp increase after all the valence electrons have been removed because of the much higher effective nuclear charge experienced by the core electrons. The first ionization energies of the elements show periodic trends that are opposite those seen for atomic radii, with smaller atoms having higher first ionization energies. Thus, first ionization energies decrease as we go down a column and increase as we proceed left to right across a row.

The **electron affinity** of an element is the energy change upon adding an electron to an atom in the gas phase, forming an anion. A negative electron affinity means that energy is released when the electron is added; hence, when the electron affinity is negative, the anion is stable. By contrast, a positive electron affinity means that the anion is not stable relative to the separated atom and electron. In general, electron affinities become more negative as we proceed from left to right across the periodic table. The halogens have the most negative electron affinities. The electron affinities of the noble gases are positive because the added electron would have to occupy a new, higher-energy subshell.

METALS, NONMETALS, AND METALLOIDS (SECTION 7.5) The elements can be categorized as metals, nonmetals, and metalloids. Most elements are metals; they occupy the left side and the middle of the periodic table. Nonmetals appear in the upper-right section of the table. Metalloids occupy a narrow band between the metals and nonmetals. The tendency of an element to exhibit the properties of metals, called the **metallic character**, increases as we proceed down a column and decreases as we proceed from left to right across a row.

Metals have a characteristic luster, and they are good conductors of heat and electricity. When metals react with nonmetals, the metal atoms are oxidized to cations and ionic substances are generally formed. Most metal oxides are basic; they react with acids to form salts and water.

Nonmetals lack metallic luster and are generally poor conductors of heat and electricity. Several are gases at room temperature. Compounds composed entirely of nonmetals are generally molecular. Nonmetals usually form anions in their reactions with metals. Nonmetal oxides are acidic; they react with bases to form salts and water. Metalloids have properties that are intermediate between those of metals and nonmetals.

TRENDS FOR GROUP 1A AND 2A METALS (SECTION 7.6) The periodic properties of the elements can help us understand the properties of groups of the representative elements. The **alkali metals** (group 1A) are soft metals with low densities and low melting points. They have the lowest ionization energies of the elements. As a result, they are very reactive toward nonmetals, easily losing their outer s electron to form $1+$ ions.

The **alkaline earth metals** (group 2A) are harder and denser, and have higher melting points than the alkali metals. They are also very reactive toward nonmetals, although not as reactive as the alkali metals. The alkaline earth metals readily lose their two outer s electrons to form $2+$ ions. Both alkali and alkaline earth metals react with hydrogen to form ionic substances that contain the **hydride ion**, H^-.

TRENDS FOR SELECTED NONMETALS (SECTION 7.7) Hydrogen is a nonmetal with properties that are distinct from any of the groups of the periodic table. It forms molecular compounds with other nonmetals, such as oxygen and the halogens.

Oxygen and sulfur are the most important elements in group 6A, the **chalcogens**. Oxygen is usually found as a diatomic molecule, O_2. **Ozone**, O_3, is an important allotrope of oxygen. Oxygen has a strong tendency to gain electrons from other elements, thus oxidizing them. In combination with metals, oxygen is usually found as the oxide ion, O^{2-}, although salts of the peroxide ion, O_2^{2-}, and superoxide ion, O_2^-, are sometimes formed. Elemental sulfur is most commonly found as S_8 molecules. In combination with metals, it is most often found as the sulfide ion, S^{2-}.

The **halogens** (group 7A) exist as diatomic molecules. The halogens have the most negative electron affinities of the elements. Thus, their chemistry is dominated by a tendency to form $1-$ ions, especially in reactions with metals.

The **noble gases** (group 8A) exist as monatomic gases. They are very unreactive because they have completely filled s and p subshells. Only the heaviest noble gases are known to form compounds, and they do so only with very active nonmetals, such as fluorine.

EP 7.2 Hypothetical elements X and Y form a linear molecule XY_2, in which both Y atoms are bonded to atom X: Y—X—Y. X_2 and Y_2 are diatomic molecules with an X—X distance of 2.04 Å and a Y—Y distance of 1.68 Å, respectively. What would you predict for the X—Y distance in the XY_2 molecule? (**a**) 0.84 Å (**b**) 1.02 Å (**c**) 1.86 Å (**d**) 2.70 Å (**e**) 3.72 Å

EP 7.3 By referring only to the periodic table, place the following atoms in order of increasing atomic size: N, O, P, Ge.

(**a**) $N < O < P < Ge$

(**b**) $P < N < O < Ge$

(**c**) $O < N < Ge < P$

(**d**) $O < N < P < Ge$

(**e**) $N < P < Ge < O$

EP 7.4 Arrange the following atoms and ions in order of increasing ionic radius: F, S^{2-}, Cl, and Se^{2-}.

(**a**) $F < S^{2-} < Cl < Se^{2-}$

(**b**) $F < Cl < S^{2-} < Se^{2-}$

(**c**) $F < S^{2-} < Se^{2-} < Cl$

(**d**) $Cl < F < Se^{2-} < S^{2-}$

(**e**) $S^{2-} < F < Se^{2-} < Cl$

EP 7.5 Arrange the following ions in order of increasing ionic radius: Br^-, Rb^+, Se^{2-}, Sr^{2+}, Te^{2-}.

(**a**) $Sr^{2+} < Rb^+ < Br^- < Se^{2-} < Te^{2-}$

(**b**) $Br^- < Sr^{2+} < Se^{2-} < Te^{2-} < Rb^+$

(**c**) $Rb^+ < Sr^{2+} < Se^{2-} < Te^{2-} < Br^-$

(**d**) $Rb^+ < Br^- < Sr^{2+} < Se^{2-} < Te^{2-}$

(**e**) $Sr^{2+} < Rb^+ < Br^- < Te^{2-} < Se^{2-}$

EP 7.6 The third ionization energy of bromine is the energy required for which of the following processes?

(**a**) $Br(g) \longrightarrow Br^+(g) + e^-$

(**b**) $Br^+(g) \longrightarrow Br^{2+}(g) + e^-$

(**c**) $Br(g) \longrightarrow Br^{2+}(g) + 2e^-$

(**d**) $Br(g) \longrightarrow Br^{3+}(g) + 3e^-$

(**e**) $Br^{2+}(g) \longrightarrow Br^{3+}(g) + e^-$

EP 7.7 Consider the following statements about first ionization energies:

(**i**) Because the effective nuclear charge for Mg is greater than that for Be, the first ionization energy of Mg is greater than that for Be.

(**ii**) The first ionization energy of O is less than that of N because in O we must pair electrons in one of the 2*p* orbitals.

(**iii**) The first ionization energy of Ar is less than that of Ne because a 3*p* electron in Ar is farther from the nucleus than a 2*p* electron in Ne.

Which of the statements i, ii, and iii is/are true? (**a**) Only one of the statements is true. (**b**) Statements i and ii are true. (**c**) Statements i and iii are true. (**d**) Statements ii and iii are true. (**e**) All three statements are true.

EP 7.8 The ground-state electron configuration of a Tc atom is $[Kr]5s^24d^5$. What is the electron configuration of a Tc^{3+} ion? (**a**) $[Kr]4d^4$ (**b**) $[Kr]5s^24d^2$ (**c**) $[Kr]5s^14d^3$ (**d**) $[Kr]5s^24d^8$ (**e**) $[Kr]4d^{10}$

EP 7.9 If an element has a large negative value for electron affinity, (**a**) it is likely to be a noble gas. (**b**) it is likely to have a large negative first ionization energy. (**c**) it is likely to be a halogen. (**d**) it is likely to have a negative value for effective nuclear charge.

EP 7.10 As you go down a column in the periodic table, first ionization energy ________ and atomic size ________. (**a**) increases, increases (**b**) increases, decreases (**c**) decreases, decreases (**d**) decreases, increases

EP 7.11 Which of the following statements about effective nuclear charge is *false*? (**a**) Effective nuclear charge generally increases as we traverse across a row of the periodic table from left to right. (**b**) In the simple model of effective nuclear charge, the core electrons completely shield the valence electrons. (**c**) In the simple model of effective nuclear charge, valence electrons do not shield one another at all. (**d**) If the nuclear charge of atom A is greater than that of atom B, then the effective nuclear charge of A is greater than that of B.

EP 7.12 As you go across a row in the periodic table from left to right, first ionization energy ________ and atomic size ________. (**a**) increases, increases (**b**) increases, decreases (**c**) decreases, decreases (**d**) decreases, increases

EP 7.13 An element conducts electricity to some extent, and it tends to form molecular compounds. What is the most likely identity of the element? (**a**) O (**b**) Cl (**c**) Al (**d**) Si (**e**) Bi

EP 7.14 An element conducts electricity, and its oxidation state in ionic compounds is usually 1+. What is the most likely identity of the element? (**a**) F (**b**) Zn (**c**) Ca (**d**) Ag (**e**) Cr

EP 7.15 Suppose that a metal oxide of formula M_2O_3 were soluble in water. What would be the major product or products of dissolving the substance in water?

(**a**) $MH_3(aq) + O_2(g)$

(**b**) $M(s) + H_2(g) + O_2(g)$

(**c**) $M^{3+}(aq) + H_2O_2(aq)$

(**d**) $M(OH)_2(aq)$

(**e**) $M(OH)_3(aq)$

EP 7.16 Consider the following oxides: SO_2, Y_2O_3, MgO, Cl_2O, N_2O_5. How many are expected to form acidic solutions in water? (**a**) 1 (**b**) 2 (**c**) 3 (**d**) 4 (**e**) 5

EP 7.17 Consider the following three statements about the reactivity of an alkali metal M with oxygen gas:

(**i**) Based on their positions in the periodic table, the expected product is the ionic oxide M_2O.

(**ii**) Some of the alkali metals produce metal peroxides or metal superoxides when they react with oxygen.

(**iii**) When dissolved in water, an alkali metal oxide produces a basic solution.

Which of the statements i, ii, and iii is/are true? (**a**) Only one of the statements is true. (**b**) Statements i and ii are true. (**c**) Statements i and iii are true. (**d**) Statements ii and iii are true. (**e**) All three statements are true.

EP 7.18 Consider the mystery element "Z." Elemental Z is a powdery solid that does not conduct electricity at all. It reacts with metals to form MZ compounds, where Z is in the −2 oxidation state. What is the likely identity of Z? (**a**) O (**b**) S (**c**) F (**d**) Cl (**e**) None of these is correct

EP 7.19 Elemental cesium reacts more violently with water than does elemental sodium. Which of the following best explains this difference in reactivity?

(**a**) Sodium has more metallic character than does cesium.

(**b**) The first ionization energy of cesium is less than that of sodium.

(**c**) The electron affinity of sodium is less than that of cesium.

(**d**) The effective nuclear charge for cesium is less than that of sodium.

(**e**) The atomic radius of cesium is less than that of sodium.

EP 7.20 Which of the following are the expected products when Sr(*s*) is added to $H_2O(l)$?

(**a**) $Sr^{2+}(aq) + OH^-(aq) + O_2(g)$

(**b**) $Sr^3 + (aq) + OH^-(aq) + H_2(g)$

(**c**) $Sr^+(aq) + OH^-(aq) + H_2(g)$

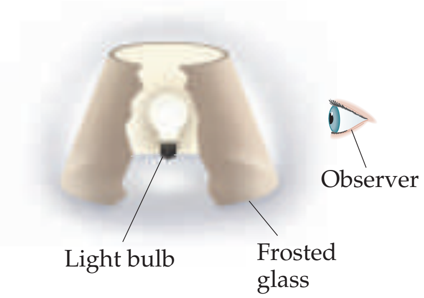
(**d**) $Sr^{2+}(aq) + H_2(g) + O_2(g)$

(**e**) $Sr^{2+}(aq) + OH^-(aq) + H_2(g)$

Exercises

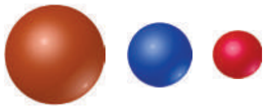
Visualizing Concepts

7.1 As discussed in the text, we can draw an analogy between the attraction of an electron to a nucleus and the act of perceiving light from a light bulb through a frosted glass shade, as shown in the illustration.

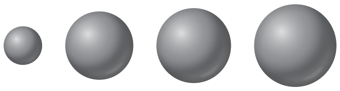


Using the simple method of estimating effective nuclear charge, Equation 7.1, how does the intensity of the light bulb and/or the thickness of the frosting change in the following cases. (**a**) Moving from boron to carbon? (**b**) Moving from boron to aluminum? [Section 7.2]

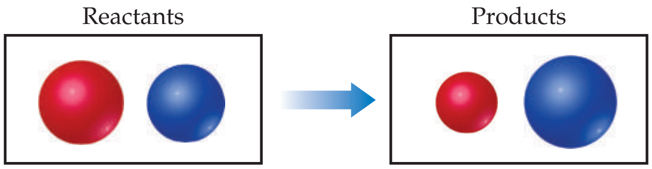
7.2 Which of these spheres represents F, which represents Br, and which represents Br^-? [Section 7.3]



7.3 Consider the Mg^{2+}, Cl^-, K^+, and Se^{2-} ions. The four spheres below represent these four ions, scaled according to ionic size. (**a**) Without referring to Figure 7.8, match each ion to its appropriate sphere. (**b**) In terms of size, between which of the spheres would you find the (i) Ca^{2+} and (ii) S^{2-} ions? [Section 7.3]

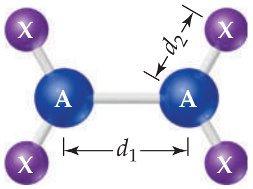


7.4 In the following reaction

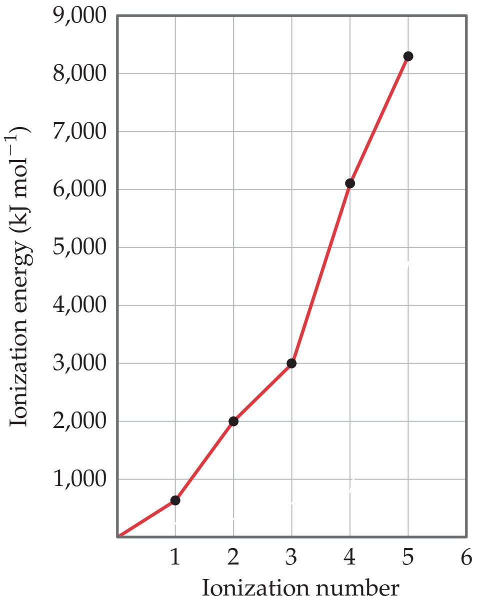


which sphere represents a metal and which represents a nonmetal? [Sections 7.3, 7.5, 7.6]

7.5 Consider the A_2X_4 molecule depicted here, where A and X are elements. The A—A bond length in this molecule is d_1, and the four A—X bond lengths are each d_2. (**a**) In terms of d_1 and d_2, how could you define the bonding atomic radii of atoms A and X? (**b**) In terms of d_1 and d_2, what would you predict for the X—X bond length of an X_2 molecule? [Section 7.2]

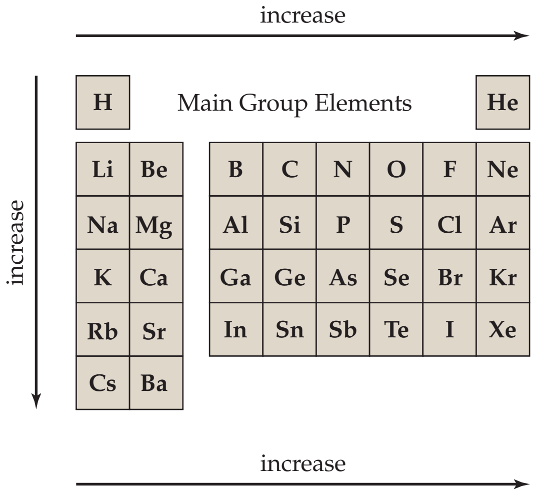


7.6 The graph below shows the ionization energies for a particular element. In which group is the element most likely a member of? [Section 7.3]

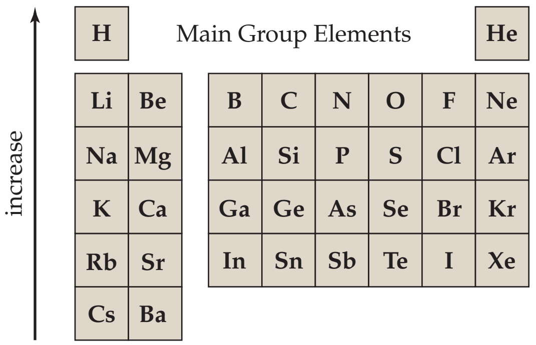


7.7 Which of the charts below shows the general periodic trends for each of the following properties of the main-group elements? (You can neglect small deviations going either left to right across a row or down a column of the periodic table.) (**1**) Bonding atomic radius, (**2**) first ionization energy, (**3**) effective nuclear charge. [Sections 7.1–7.3]

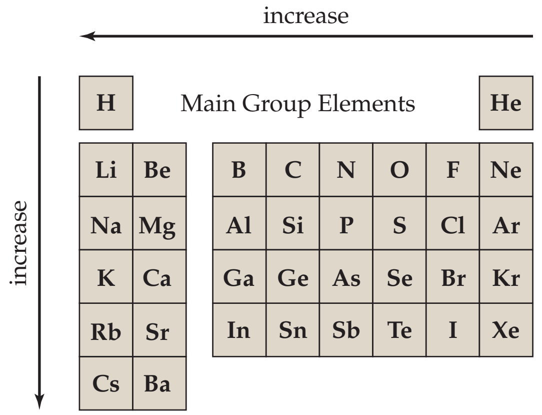
(i)



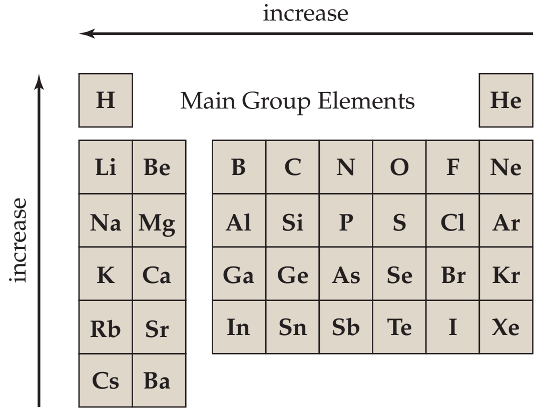
(ii)



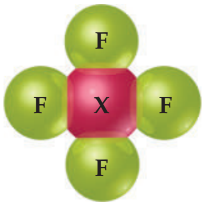
(iii)



(iv)



7.8 An element X reacts with $F_2(g)$ to form the molecular product shown here. (**a**) Write a balanced equation for this reaction (do not worry about the phases for X and the product). (**b**) If X were a metal, what oxidation state must it have? (**c**) Suggest an identity for X if X is a nonmetal. [Sections 7.4–7.6]



Periodic Table; Effective Nuclear Charge (Sections 7.1 and 7.2)

7.9 Group 1A and 2A elements are sometimes called, collectively, "the s-block." Therefore, what is an analogous name for the entire collection of the group 3A, 4A, 5A, 6A, 7A, and 8A elements?

7.10 The prefix *eka-* comes from the Sanskrit word for "one." Mendeleev used this prefix to indicate that the unknown element was one place away from the known element that followed the prefix. For example, *eka-silicon*, which we now call germanium, is one element below silicon. Mendeleev also predicted the existence of *eka-manganese*, which was not experimentally confirmed until 1937 because this element is radioactive and does not occur in nature. Based on the periodic table shown in Figure 7.1, what do we now call the element Mendeleev called *eka-manganese*?

7.11 (**a**) The five most abundant elements in Earth's crust are O, Si, Al, Fe, and Ca. Referring to Figure 7.1, are any of these elements among those known before 1700? If so, which ones? (**b**) Seven of the nine elements known since ancient times are metals. Referring to Table 4.5, are these metals mostly found at the bottom or top of the activity series?

7.12 Moseley's experiments on X rays emitted from atoms led to the concept of atomic numbers. (**a**) If arranged in order of increasing atomic mass, which element would come after chlorine? (**b**) Describe two ways in which the properties of this element differ from the other elements in group 8A.

7.13 Among elements 1–18, which element or elements have the smallest effective nuclear charge if we use Equation 7.1 to calculate Z_{eff}? Which element or elements have the largest effective nuclear charge?

7.14 Which of the following statements about effective nuclear charge for the outermost valence electron of an atom is *incorrect*?

(**a**) The effective nuclear charge can be thought of as the true nuclear charge minus a screening constant due to the other electrons in the atom.

(**b**) Effective nuclear charge increases going left to right across a row of the periodic table.

(**c**) Valence electrons screen the nuclear charge more effectively than do core electrons.

(**d**) The effective nuclear charge shows a sudden decrease when we go from the end of one row to the beginning of the next row of the periodic table.

(**e**) The change in effective nuclear charge going down a column of the periodic table is generally less than that going across a row of the periodic table.

7.15 Detailed calculations show that the value of Z_{eff} for the outermost electrons in Na and K atoms is 2.51+ and 3.49+, respectively. (**a**) What value do you estimate for Z_{eff} experienced by the outermost electron in both Na and K by assuming core electrons contribute 1.00 and valence electrons contribute 0.00 to the screening constant? (**b**) What values do you estimate for Z_{eff} using Slater's rules? (**c**) Which approach gives a more accurate estimate of Z_{eff}? (**d**) Does either method of approximation account for the gradual increase in Z_{eff} that occurs upon moving down a group? (**e**) Predict Z_{eff} for the outermost electrons in the Rb atom based on the calculations for Na and K.

7.16 Detailed calculations show that the value of Z_{eff} for the outermost electrons in Si and Cl atoms is 4.29+ and 6.12+, respectively. (**a**) What value do you estimate for Z_{eff} experienced by the outermost electron in both Si and Cl by assuming core electrons contribute 1.00 and valence electrons contribute 0.00 to the screening constant? (**b**) What values do you estimate for Z_{eff} using Slater's rules? (**c**) Which approach gives a more accurate estimate of Z_{eff}? (**d**) Which method of approximation more accurately accounts for the steady increase in Z_{eff} that occurs upon moving left to right across a period? (**e**) Predict Z_{eff} for a valence electron in P, phosphorus, based on the calculations for Si and Cl.

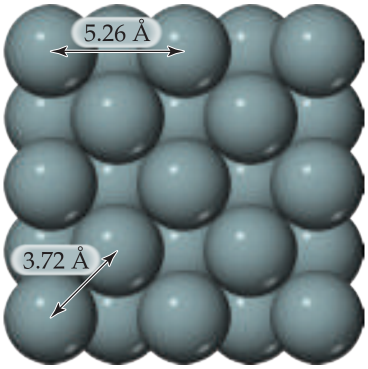
7.17 Which will experience the greater effective nuclear charge, the electrons in the $n = 3$ shell in Ar or the $n = 3$ shell in Kr? Which is more likely to be closer to the nucleus?

7.18 Arrange the following atoms in order of increasing effective nuclear charge experienced by the electrons in the $n = 3$ electron shell: K, Mg, P, Rh, Ti.

Atomic and Ionic Radii; Electronic Configuration of Ions (Section 7.3)

7.19 If you look up the radius of the Cl atom in various online sources, you will find values ranging from 79 to 182 pm (picometers; $1\ \text{pm} = 1 \times 10^{-12}\ \text{m}$). The most common values are 100 pm and 182 pm. What can you conclude from these data? (**a**) Chemists must be doing something wrong if they cannot agree on a simple number like this. (**b**) The 100 pm number is probably the van der Waals radius, whereas the 182 pm number is probably the bonding atomic radius. (**c**) The 100 pm number is probably the bonding atomic radius, whereas the 182 pm number is probably the van der Waals radius. (**d**) The databases are probably including Cl ions in with atoms; so the 100 pm value is probably the chlorine anion radius, whereas the 182 pm value is probably the Cl atomic radius.

7.20 With the exception of helium, the noble gases condense to form solids when they are cooled sufficiently. At temperatures below 83 K, argon forms a close-packed solid whose structure is shown below. (**a**) What is the apparent radius of an argon atom in solid argon, assuming the atoms touch as shown in this figure? (**b**) Is this value larger or smaller than the bonding atomic radius estimated for argon in Figure 7.7? (**c**) Based on this comparison, would you say that the atoms are held together by chemical bonds in solid argon?



7.21 Tungsten has the highest melting point of any metal in the periodic table: 3422 °C. The distance between the centers of W atoms in tungsten metal is 2.74 Å. (**a**) What is the atomic radius of a tungsten atom in this environment? (This radius is called the *metallic radius*.) (**b**) If you put tungsten metal under high pressure, predict what would happen to the distance between W atoms.

7.22 Which of the following statements about the bonding atomic radii in Figure 7.7 is *incorrect*?

(**a**) For a given period, the radii of the representative elements generally decrease from left to right across a period.

(**b**) The radii of the representative elements for the $n = 3$ period are all larger than those of the corresponding elements in the $n = 2$ period.

(**c**) For most of the representative elements, the change in radius from the $n = 2$ to the $n = 3$ period is greater than the change in radius from $n = 3$ to $n = 4$.

(**d**) The radii of the transition elements generally increase moving from left to right within a period. (**v**) The large radii of the group 1A elements are due to their relatively small effective nuclear charges.

7.23 Estimate the As—I bond length from the data in Figure 7.7 and compare your value to the experimental As—I bond length in arsenic triiodide, AsI_3, 2.55 Å.

7.24 The experimental Bi—I bond length in bismuth triiodide, BiI_3, is 2.81 Å. Based on this value and the data in Figure 7.7, predict the atomic radius of Bi.

7.25 Using only the periodic table, arrange each set of atoms in order from largest to smallest. (**a**) K, Li, Cs, (**b**) Pb, Sn, Si, (**c**) F, O, N

7.26 Using only the periodic table, arrange each set of atoms in order of increasing radius. (**a**) Ba, Ca, Na, (**b**) In, Sn, As, (**c**) Al, Be, Si.

7.27 Identify each statement as true or false. (**a**) Cations are larger than their corresponding neutral atoms. (**b**) Li^+ is smaller than Li. (**c**) Cl^- is bigger than I^-.

7.28 For each set of atoms and ions, pick the smallest one.

(**a**) I, I^+, I^-

(**b**) Be^{2+}, Ca^{2+}, Mg^{2+}

(**c**) Fe, Fe^{2+}, Fe^{3+}

7.29 For each ion, identify the neutral atom that is isoelectronic with it. (**a**) Ga^{3+} (**b**) Zr^{4+} (**c**) Mn^{7+} (**d**) I^- (**e**) Pb^{2+}

7.30 For each ion, identify the neutral atom that is isoelectronic with it. (**a**) Cl^- (**b**) Sc^{3+} (**c**) Fe^{2+} (**d**) Zn^{2+} (**e**) Sn^{4+}

7.31 Consider the isoelectronic ions F^- and Na^+. (**a**) Which ion is smaller? (**b**) Using Equation 7.1 and assuming that core electrons contribute 1.00 and valence electrons contribute 0.00 to the screening constant, *S*, calculate Z_{eff} for the $2p$ electrons in both ions. (**c**) Repeat this calculation using Slater's rules to estimate the screening constant, *S*. (**d**) For isoelectronic ions, how are effective nuclear charge and ionic radius related?

7.32 Consider the isoelectronic ions Cl^- and K^+. (**a**) Which ion is smaller? (**b**) Using Equation 7.1 and assuming that core electrons contribute 1.00 and valence electrons contribute nothing to the screening constant, *S*, calculate Z_{eff} for these two ions. (**c**) Repeat this calculation using Slater's rules to estimate the screening constant, *S*. (**d**) For isoelectronic ions, how are effective nuclear charge and ionic radius related?

7.33 Consider S, Cl, and K and their most common ions. (**a**) List the atoms in order of increasing size. (**b**) List the ions in order of increasing size. (**c**) Explain any differences in the orders of the atomic and ionic sizes.

7.34 Arrange each of the following sets of atoms and ions in order of increasing size. (**a**) Se^{2-}, Te^{2-}, Se (**b**) Co^{3+}, Fe^{2+}, Fe^{3+} (**c**) Ca, Ti^{4+}, Sc^{3+} (**d**) Be^{2+}, Na^+, Ne

7.35 True or false? (**a**) O^{2-} is smaller than O. (**b**) S^{2-} is smaller than O^{2-}. (**c**) S^{2-} is larger than K^+. (**d**) K^+ is larger than Ca^{2+}.

7.36 In the ionic compounds LiF, NaCl, KBr, and RbI, the measured cation–anion distances are 2.01 Å (Li–F), 2.82 Å (Na–Cl), 3.30 Å (K–Br), and 3.67 Å (Rb–I), respectively. (**a**) Predict the cation–anion distance using the values of ionic radii given in Figure 7.8. (**b**) Calculate the difference between the experimentally measured ion–ion distances and the ones predicted from Figure 7.8. (**c**) What estimates of the cation–anion distance would you obtain for these four compounds using neutral atom *bonding atomic radii*? Are these estimates as accurate as the estimates using ionic radii?

7.37 Write the electron configurations for the following ions, and determine which have noble-gas configurations. (**a**) Co^{2+} **b**) Sn^{2+} (**c**) Zr^{4+} (**d**) Ag^+ (**e**) S^{2-}

7.38 Write the electron configurations for the following ions, and determine which have noble-gas configurations. (**a**) Ru^{3+} (**b**) As^{3-} (**c**) Y^{3+} (**d**) Pd^{2+} (**e**) Pb^{2+} (**f**) Au^{3+}

7.39 Which of the ions Ni^{2+}, Fe^{2+}, Co^{3+}, and Pt^{2+} has an electron configuration of nd^8 ($n = 3, 4, 5, \ldots$)? (**a**) Ni^{2+} (**b**) Fe^{2+} (**c**) Co^{3+} (**d**) Pt^{2+} (**e**) More than one of these

7.40 Which of the ions Ni^{2+}, Fe^{2+}, Co^{3+}, and Pt^{2+} has an electron configuration of nd^6 ($n = 3, 4, 5, \ldots$)? (**a**) Ni^{2+} (**b**) Fe^{2+} (**c**) Co^{3+} (**d**) Pt^{2+} (**e**) More than one of these

Ionization Energy and Electron Affinity (Section 7.4)

7.41 (**a**) Write an equation for the second electron affinity of chlorine. (**b**) Would you predict a positive or a negative quantity for this process?

7.42 True or false: If the electron affinity for an element is a negative number, then the anion of the element is more stable than the neutral atom.

7.43 Write equations that show the processes that describe the first, second, and third ionization energies of an aluminum atom. Which process would require the least amount of energy?

7.44 Write equations that show the process for (**a**) the first two ionization energies of lead and (**b**) the fourth ionization energy of zirconium.

7.45 Which element has the highest second ionization energy: Li, K, or Be?

7.46 Identify each statement as true or false. (**a**) Ionization energies are always negative quantities. (**b**) Oxygen has a larger first ionization energy than fluorine. (**c**) The second ionization energy of an atom is always greater than its first ionization energy. (**d**) The third ionization energy is the energy needed to ionize three electrons from a neutral atom.

7.47 (**a**) Pick the correct word to complete the sentence: The larger the atom, the (smaller/larger) its first ionization energy. (**b**) Which element in the periodic table has the largest first ionization energy? (**c**) Which element has the smallest first ionization energy?

7.48 (**a**) What is the trend in first ionization energies as one proceeds down the group 7A elements? (**b**) Do the atomic radii of the group 7A elements show the same trend as first ionization energies? (**c**) What is the trend in first ionization energies as one moves across the fourth period from K to Kr? (**d**) Do the atomic radii of period 4 elements show the same trend as first ionization energies?

7.49 Based on their positions in the periodic table, predict which atom of the following pairs will have the smaller first ionization energy. (**a**) Cl, Ar, (**b**) Be, Ca, (**c**) K, Co, (**d**) S, Ge, (**e**) Sn, Te

7.50 For each of the following pairs, predict which element has the smaller first ionization energy. (**a**) Ti, Ba, (**b**) Ag, Cu, (**c**) Ge, Cl, (**d**) Pb, Sb

7.51 Would a neutral K atom or a K^+ ion have a more negative value of electron affinity?

7.52 What is the relationship between the ionization energy of an anion with a 1− charge such as F^- and the electron affinity of the neutral atom, F?

7.53 Consider the first ionization energy of neon and the electron affinity of fluorine. (**a**) Write equations, including electron configurations, for each process. (**b**) These two quantities have opposite signs. Which will be positive, and which will be negative? (**c**) Predict which of these quantities will be larger in magnitude.

7.54 Consider the following equation:

$$Ca^+(g) + e^- \longrightarrow Ca(g)$$

Which of the following statements are true?

(**i**) The energy change for this process is the electron affinity of the Ca^+ ion.

(**ii**) The energy change for this process is the negative of the first ionization energy of the Ca atom.

(**iii**) The energy change for this process is the negative of the electron affinity of the Ca atom.

(**a**) Only statement i is true. (**b**) Only statement ii is true. (**c**) Only statement iii is true. (**d**) Only statements i and ii are true. (**e**) All three statements are true.

Properties of Metals and Nonmetals (Section 7.5)

7.55 (**a**) Does metallic character increase, decrease, or remain unchanged as you go from left to right across a row of the periodic table? (**b**) Does metallic character increase, decrease, or remain unchanged as you go down a column of the periodic table? (**c**) Are the periodic trends in (a) and (b) the same as or different from those for first ionization energy?

7.56 You read the following statement about two solid elements X and Y: Experiments show that the first ionization energy of X is twice as great as that of Y. Which element has the greater metallic character?

7.57 True or false: An element that commonly forms a cation is a metal.

7.58 True or false: Because elements that form cations are metals, and elements that form anions are nonmetals, elements that do not form ions are metalloids.

7.59 Predict whether each of the following oxides is ionic or molecular: SnO_2, Al_2O_3, CO_2, Li_2O, Fe_2O_3, H_2O.

7.60 Some metal oxides, such as Sc_2O_3, do not react with pure water, but they do react when the solution becomes either acidic or basic. Do you expect Sc_2O_3 to react when the solution becomes acidic or when it becomes basic? Write a balanced chemical equation to support your answer.

7.61 Would you expect manganese(II) oxide, MnO, to react more readily with $HCl(aq)$ or $NaOH(aq)$?

7.62 Arrange the following oxides in order of increasing acidity: CO_2, CaO, Al_2O_3, SO_3, SiO_2, P_2O_5.

7.63 Chlorine reacts with oxygen to form Cl_2O_7. (**a**) What is the name of this product (see Table 2.6)? (**b**) Write a balanced equation for the formation of $Cl_2O_7(l)$ from the elements. (**c**) Would you expect Cl_2O_7 to be more reactive toward $H^+(aq)$ or $OH^-(aq)$? (**d**) If the oxygen in Cl_2O_7 is considered to have the −2 oxidation state, what is the oxidation state of the Cl? What is the electron configuration of Cl in this oxidation state?

7.64 An element X reacts with oxygen to form XO_2 and with chlorine to form XCl_4. XO_2 is a white solid that melts at high temperatures (above 1000 °C). Under usual conditions, XCl_4 is a colorless liquid with a boiling point of 58 °C. (**a**) XCl_4 reacts with water to form XO_2 and another product. What is the likely identity of the other product? (**b**) Do you think that element X is a metal, nonmetal, or metalloid? (**c**) Which is the most likely identity of X: Zr, C, Si, P, or S?

7.65 Write balanced equations for the following reactions. (**a**) barium oxide with water, (**b**) iron(II) oxide with perchloric acid, (**c**) sulfur trioxide with water, (**d**) carbon dioxide with aqueous sodium hydroxide.

7.66 Write balanced equations for the following reactions. (**a**) potassium oxide with water, (**b**) diphosphorus trioxide with water, (**c**) chromium(III) oxide with dilute hydrochloric acid, (**d**) selenium dioxide with aqueous potassium hydroxide.

Group Trends in Metals and Nonmetals (Sections 7.6 and 7.7)

7.67 Arrange these elements in order of increasing reactivity: Ca, Mg, K.

7.68 Silver and rubidium both form +1 ions. Predict which of these elements is more reactive to form ionic compounds.

7.69 Write a balanced equation for the reaction that occurs in each of the following cases. (**a**) Potassium metal is exposed to an atmosphere of chlorine gas. (**b**) Strontium oxide is added to water. (**c**) A fresh surface of lithium metal is exposed to oxygen gas. (**d**) Sodium metal reacts with molten sulfur.

7.70 Write a balanced equation for the reaction that occurs in each of the following cases. (**a**) Cesium is added to water. (**b**) Strontium is added to water. (**c**) Sodium reacts with oxygen. (**d**) Calcium reacts with iodine.

7.71 (**a**) As described in Section 7.7, the alkali metals react with hydrogen to form hydrides and react with halogens to form halides. Compare the roles of hydrogen and halogens in these reactions. Write balanced equations for the reaction of fluorine with calcium and for the reaction of hydrogen with calcium. (**b**) What is the oxidation number and electron configuration of calcium in each product?

7.72 Potassium and hydrogen react to form the ionic compound potassium hydride. (**a**) Write a balanced equation for this reaction. (**b**) Use the data in Figures 7.11 and 7.13 to determine the energy change in kJ/mol for the following two reactions:

$$K(g) + H(g) \longrightarrow K^+(g) + H^-(g)$$
$$K(g) + H(g) \longrightarrow K^-(g) + H^+(g)$$

(**c**) Based on your calculated energy changes in (b), which of these reactions is energetically more favorable (or less unfavorable)? (**d**) Is your answer to (c) consistent with the description of potassium hydride as containing hydride ions?

7.73 Consider the elements bromine and chlorine. For each element, write its: (**a**) electron configuration, (**b**) most common ionic charge, (**c**) first ionization energy, (**d**) primary reaction toward water, (**e**) electron affinity, (**f**) atomic radius.

7.74 Little is known about the properties of astatine, At, because of its rarity and high radioactivity. Nevertheless, it is possible for us to make many predictions about its properties. (**a**) Do you expect the element to be a gas, liquid, or solid at room temperature? (**b**) Would you expect At to be a metal, nonmetal, or metalloid? (**c**) What is the chemical formula of the compound it forms with Na?

7.75 Until the early 1960s, the group 8A elements were called the inert gases. (**a**) Why was the term *inert gases* dropped? (**b**) What discovery triggered this change in name? (**c**) What name is applied to the group now?

7.76 (**a**) Why does xenon react with fluorine, whereas neon does not? (**b**) Using appropriate reference sources, look up the bond lengths of Xe—F bonds in several molecules. How do these numbers compare to the bond lengths calculated from the atomic radii of the elements?

7.77 Write a balanced equation for the reaction that occurs in each of the following cases. (**a**) Ozone decomposes to dioxygen. (**b**) Xenon reacts with fluorine. (Write three different equations.) (**c**) Sulfur reacts with hydrogen gas. (**d**) Fluorine reacts with water.

7.78 Write a balanced equation for the reaction that occurs in each of the following cases. (**a**) Chlorine reacts with water. (**b**) Barium metal is heated in an atmosphere of hydrogen gas. (**c**) Lithium reacts with sulfur. (**d**) Fluorine reacts with magnesium metal.

Additional Exercises

7.79 Consider the stable elements through lead ($Z = 82$). In how many instances are the atomic weights of the elements out of order relative to the atomic numbers of the elements?

7.80 Figure 7.4 shows the radial probability distribution functions for the 2*s* orbitals and 2*p* orbitals. (**a**) Which orbital, 2*s* or 2*p*, has more electron density close to the nucleus? (**b**) How would you modify Slater's rules to adjust for the difference in electronic penetration of the nucleus for the 2*s* and 2*p* orbitals?

7.81 (**a**) If the core electrons were totally effective at screening the valence electrons and the valence electrons provided no screening for each other, what would be the effective nuclear charge acting on the 3*s* and 3*p* valence electrons in P? (**b**) Repeat these calculations using Slater's rules. (**c**) Detailed calculations indicate that the effective nuclear charge is 5.6+ for the 3*s* electrons and 4.9+ for the 3*p* electrons. Why are the values for the 3*s* and 3*p* electrons different? (**d**) If you remove a single electron from a P atom, which orbital will it come from?

7.82 In the series of group 5A hydrides, of general formula MH_3, the measured bond distances are P—H, 1.419 Å; As—H, 1.519 Å; Sb—H, 1.707 Å. (**a**) Compare these values with those estimated by use of the atomic radii in Figure 7.7. (**b**) Explain the steady increase in M—H bond distance in this series in terms of the electron configurations of the M atoms.

7.83 In Table 7.8, the bonding atomic radius of neon is listed as 0.58 Å, whereas that for xenon is listed as 1.40 Å. A classmate of yours states that the value for Xe is more realistic than the one for Ne. Is she correct? If so, what is the basis for her statement?

7.84 The As—As bond length in elemental arsenic is 2.48 Å. The Cl—Cl bond length in Cl_2 is 1.99 Å. (**a**) Based on these data, what is the predicted As—Cl bond length in arsenic trichloride, $AsCl_3$, in which each of the three Cl atoms is bonded to the As atom? (**b**) What bond length is predicted for $AsCl_3$, using the atomic radii in Figure 7.7?

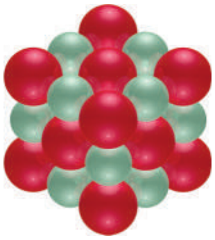
7.85 The following observations are made about two hypothetical elements A and B: The A—A and B—B bond lengths in the elemental forms of A and B are 2.36 and 1.94 Å, respectively. A and B react to form the binary compound AB_2, which has a *linear* structure (that is, $\angle B{-}A{-}B = 180°$). Based on these statements, predict the separation between the two B nuclei in a molecule of AB_2.

7.86 Elements in group 7A in the periodic table are called the halogens; elements in group 6A are called the chalcogens. (**a**) What is the most common oxidation state of the chalcogens compared to the halogens? (**b**) For each of the following periodic properties, state whether the halogens or the chalcogens have larger values: atomic radii, ionic radii of the most common oxidation state, first ionization energy, second ionization energy.

7.87 (**a**) Which ion is smaller, Co^{3+} or Co^{4+}? (**b**) In a lithium-ion battery that is discharging to power a device, for every Li^+ that inserts into the lithium cobalt oxide electrode, a Co^{4+} ion must be reduced to a Co^{3+} ion to balance charge. Using the *CRC Handbook of Chemistry and Physics* or other standard reference, find the ionic radii of Li^+, Co^{3+}, and Co^{4+}. Order these ions from smallest to largest. (**c**) Will the lithium cobalt oxide cathode expand or contract as lithium ions are inserted? (**d**) Lithium is not nearly as abundant as sodium. If sodium-ion batteries were developed that function in the same manner as lithium-ion batteries, do you think "sodium cobalt oxide" would still work as the electrode material? Explain.

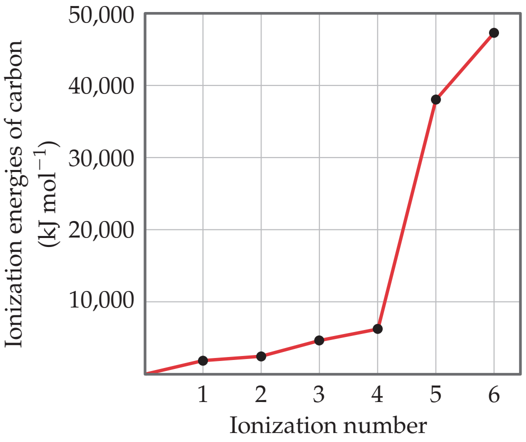
(**e**) If you don't think cobalt would work as the redox-active partner ion in the sodium version of the electrode, suggest an alternative metal ion and explain your reasoning.

7.88 The ionic substance strontium oxide, SrO, forms from the reaction of strontium metal with molecular oxygen. The arrangement of the ions in solid SrO is analogous to that in solid NaCl:



(**a**) Write a balanced equation for the formation of SrO(s) from its elements. (**b**) Based on the ionic radii in Figure 7.8, predict the length of the side of the cube in the figure (the distance from the center of an atom at one corner to the center of an atom at a neighboring corner). (**c**) The density of SrO is 5.10 g/cm^3. Given your answer to part (b), how many formula units of SrO are contained in the cube shown here?

7.89 Explain the variation in the ionization energies of carbon, as displayed in this graph:



7.90 Group 4A elements have much more negative electron affinities than their neighbors in groups 3A and 5A (see Figure 7.13). Which of the following statements best explains this observation?

(**a**) The group 4A elements have much higher first ionization energies than their neighbors in groups 3A and 5A.

(**b**) The addition of an electron to a group 4A element leads to a half-filled np^3 outer electron configuration.

(**c**) The group 4A elements have unusually large atomic radii.

(**d**) The group 4A elements are easier to vaporize than are the group 3A and 5A elements.

7.91 In the chemical process called *electron transfer*, an electron is transferred from one atom or molecule to another. (We discuss electron transfer extensively in Chapter 20.) A simple electron transfer reaction is

$$A(g) + A(g) \longrightarrow A^+(g) + A^-(g)$$

In terms of the ionization energy and electron affinity of atom A, what is the energy change for this reaction? For a representative nonmetal such as chlorine, is this process exothermic? For a representative metal such as sodium, is this process exothermic?

7.92 (**a**) Use orbital diagrams to illustrate what happens when an oxygen atom gains two electrons. (**b**) Why does O^{3-} not exist?

7.93 Use electron configurations to explain the following observations: (**a**) The first ionization energy of phosphorus is greater than that of sulfur. (**b**) The electron affinity of nitrogen is lower (less negative) than those of both carbon and oxygen. (**c**) The second ionization energy of oxygen is greater than the first ionization energy of fluorine. (**d**) The third ionization energy of manganese is greater than those of both chromium and iron.

7.94 Identify two ions that have the following ground-state electron configurations: (**a**) [Ar] (**b**) [Ar]$3d^5$ (**c**) [Kr]$5s^2 4d^{10}$

7.95 Which of the following chemical equations is connected to the definitions of (**a**) the first ionization energy of oxygen, (**b**) the second ionization energy of oxygen, and (**c**) the electron affinity of oxygen?

(**i**) $O(g) + e^- \longrightarrow O^-(g)$
(**ii**) $O(g) \longrightarrow O^+(g) + e^-$
(**iii**) $O(g) + 2e^- \longrightarrow O^{2-}(g)$
(**iv**) $O(g) \longrightarrow O^{2+}(g) + 2e^-$
(**v**) $O^+(g) \longrightarrow O^{2+}(g) + e^-$

7.96 Hydrogen is an unusual element because it behaves in some ways like the alkali metal elements and in other ways like nonmetals. Its properties can be explained in part by its electron configuration and by the values for its ionization energy and electron affinity. (**a**) Explain why the electron affinity of hydrogen is much closer to the values for the alkali elements than for the halogens. (**b**) Is the following statement true? "Hydrogen has the smallest bonding atomic radius of any element that forms chemical compounds." If not, correct it. If it is correct, explain in terms of electron configurations. (**c**) Explain why the ionization energy of hydrogen is closer to the values for the halogens than for the alkali metals. (**d**) The hydride ion is H^-. Write out the process corresponding to the first ionization energy of the hydride ion. (**e**) How does the process in part (d) compare to the process for the electron affinity of a neutral hydrogen atom?

7.97 The first ionization energy of the oxygen molecule is the energy required for the following process:

$$O_2(g) \longrightarrow O_2^+(g) + e^-$$

The energy needed for this process is 1175 kJ/mol, very similar to the first ionization energy of Xe. Would you expect O_2 to react with F_2? If so, suggest a product or products of this reaction.

7.98 It is possible to define *metallic character* as we do in this book and base it on the reactivity of the element and the ease with which it loses electrons. Alternatively, you could measure how well electricity is conducted by each of the elements to determine how "metallic" the elements are. On the basis of conductivity, there is not much of a trend in the periodic table: Silver is the most conductive metal, and manganese the least. Look up the first ionization energies of silver and manganese; which of these two elements would you call more metallic based on the way we define it in this book?

7.99 Which of the following is the expected product of the reaction of K(s) and $H_2(g)$? (**a**) KH(s), (**b**) $K_2H(s)$, (**c**) $KH_2(s)$, (**d**) $K_2H_2(s)$, (**e**) K(s) and $H_2(g)$ will not react with one another.

7.100 Elemental cesium reacts more violently with water than does elemental sodium. Which of the following best explains this difference in reactivity? (**a**) Sodium has greater metallic character than does cesium. (**b**) The first ionization energy of cesium is less than that of sodium. (**c**) The electron affinity of sodium is smaller than that of cesium. (**d**) The effective nuclear charge for cesium is less than that of sodium. (**e**) The atomic radius of cesium is smaller than that of sodium.

7.101 (**a**) One of the alkali metals reacts with oxygen to form a solid white substance. When this substance is dissolved in water, the solution gives a positive test for hydrogen peroxide, H_2O_2. When the solution is tested in a burner flame, a lilac-purple flame is produced. What is the likely identity of the metal? (**b**) Write a balanced chemical equation for the reaction of the white substance with water.

7.102 A historian discovers a nineteenth-century notebook in which some observations, dated 1822, were recorded on a substance thought to be a new element. Here are some of the data recorded in the notebook: "Ductile, silver-white, metallic looking. Softer than lead. Unaffected by water. Stable in air. Melting point: 153 °C. Density: 7.3 g/cm^3. Electrical conductivity: 20% that of copper. Hardness: About 1% as hard as iron. When 4.20 g of the unknown is heated in an excess of oxygen, 5.08 g of a white solid is formed. The solid could be sublimed by heating to over 800 °C." (**a**) Using information in the text and the *CRC Handbook of Chemistry and Physics*, and making allowances for possible variations in numbers from current values, identify the element reported. (**b**) Write a balanced chemical equation for the reaction with oxygen. (**c**) Judging from Figure 7.1, might this nineteenth-century investigator have been the first to discover a new element?

7.103 In April 2010, a research team reported that it had made Element 117. This discovery was confirmed in 2012 by additional experiments. Write the ground-state electron configuration for Element 117 and estimate values for its first ionization energy, electron affinity, atomic size, and common oxidation state based on its position in the periodic table.

7.104 We show in Chapter 12 that semiconductors are materials that conduct electricity better than nonmetals but not as well as metals. The only two elements in the periodic table that are technologically useful semiconductors are silicon and germanium. Integrated circuits in computer chips today are based on silicon. Compound semiconductors are also used in the electronics industry. Examples are gallium arsenide, GaAs; gallium phosphide, GaP; cadmium sulfide, CdS; and cadmium selenide, CdSe. (**a**) What is the relationship between the compound semiconductors' compositions and the positions of their elements on the periodic table relative to Si and Ge? (**b**) Workers in the semiconductor industry refer to "II–VI" and "III–V" materials, using Roman numerals. Can you identify which compound semiconductors are II–VI and which are III–V? (**c**) Suggest other compositions of compound semiconductors based on the positions of their elements in the periodic table.

7.105 Moseley established the concept of atomic number by studying X rays emitted by the elements. The X rays emitted by some of the elements have the following wavelengths:

Element	Wavelength (Å)
Ne	14.610
Ca	3.358
Zn	1.435
Zr	0.786
Sn	0.491

(**a**) Calculate the frequency, ν, of the X rays emitted by each of the elements, in Hz. (**b**) Plot the square root of ν versus the atomic number of the element. What do you observe about the plot? (**c**) Explain how the plot in part (b) allowed Moseley to predict the existence of undiscovered elements. (**d**) Use the result from part (b) to predict the X-ray wavelength emitted by iron. (**e**) A particular element emits X rays with a wavelength of 0.980 Å. What element do you think it is?

7.106 (**a**) Write the electron configuration for Li and estimate the effective nuclear charge experienced by the valence electron. (**b**) The energy of an electron in a one-electron atom or ion equals $(-2.18 \times 10^{-18}\,\text{J})\left(\frac{Z^2}{n^2}\right)$, where Z is the nuclear charge and n is the principal quantum number of the electron. Estimate the first ionization energy of Li. (**c**) Compare the result of your calculation with the value reported in Table 7.4 and explain the difference. (**d**) What value of the effective nuclear charge gives the proper value for the ionization energy? Does this agree with your explanation in part (c)?

7.107 One way to measure ionization energies is ultraviolet photoelectron spectroscopy (PES), a technique based on the photoelectric effect. (Section 6.2) In PES, monochromatic light is directed onto a sample, causing electrons to be emitted. The kinetic energy of the emitted electrons is measured. The difference between the energy of the photons and the kinetic energy of the electrons corresponds to the energy needed to remove the electrons (that is, the ionization energy). Suppose that a PES experiment is performed in which mercury vapor is irradiated with ultraviolet light of wavelength 58.4 nm. (**a**) What is the energy of a photon of this light, in joules? (**b**) Write an equation that shows the process corresponding to the first ionization energy of Hg. (**c**) The kinetic energy of the emitted electrons is measured to be 1.72×10^{-18} J. What is the first ionization energy of Hg, in kJ/mol? (**d**) Using Figure 7.11, determine which of the halogen elements has a first ionization energy closest to that of mercury.

7.108 When magnesium metal is burned in air (Figure 3.5), two products are produced. One is magnesium oxide, MgO. The other is the product of the reaction of Mg with molecular nitrogen, magnesium nitride. When water is added to magnesium nitride, it reacts to form magnesium oxide and ammonia gas. (**a**) Based on the charge of the nitride ion (Table 2.5), predict the formula of magnesium nitride. (**b**) Write a balanced equation for the reaction of magnesium nitride with water. What is the driving force for this reaction? (**c**) In an experiment, a piece of magnesium ribbon is burned in air in a crucible. The mass of the mixture of MgO and magnesium nitride after burning is 0.470 g. Water is added to the crucible, further reaction occurs, and the crucible is heated to dryness until the final product is 0.486 g of MgO. What was the mass percentage of magnesium nitride in the mixture obtained after the initial burning? (**d**) Magnesium nitride can also be formed by reaction of the metal with ammonia at high temperature. Write a balanced equation for this reaction. If a 6.3-g Mg ribbon reacts with 2.57 g $NH_3(g)$ and the reaction goes to completion, which component is the limiting reactant? What mass of $H_2(g)$ is formed in the reaction? (**e**) The standard enthalpy of formation of solid magnesium nitride is −461.08 kJ/mol. Calculate the standard enthalpy change for the reaction between magnesium metal and ammonia gas.

7.109 Potassium superoxide, KO_2, is often used in oxygen masks (such as those used by firefighters) because KO_2 reacts with CO_2 to release molecular oxygen. Experiments indicate that 2 mol of $KO_2(s)$ react with each mole of $CO_2(g)$. (**a**) The products of the reaction are $K_2CO_3(s)$ and $O_2(g)$. Write a balanced equation for the reaction between $KO_2(s)$ and $CO_2(g)$. (**b**) Indicate the oxidation number for each atom involved in the reaction in part (a). What elements are being oxidized and reduced? (**c**) What mass of $KO_2(s)$ is needed to consume 18.0 g $CO_2(g)$? What mass of $O_2(g)$ is produced during this reaction?

Design an Experiment

In this chapter we have seen that the reaction of potassium metal with oxygen leads to a product that we might not expect—namely, potassium superoxide, $KO_2(s)$. Let's design some experiments to learn more about this unusual product.

(**a**) One of your team members proposes that the capacity to form a superoxide such as KO_2 is related to a low value for the first ionization energy. How would you go about testing this hypothesis for the metals of group 1A? What other periodic property of the alkali metals might be considered as a factor favoring superoxide formation?

(**b**) $KO_2(s)$ is the active ingredient in many breathing masks used by firefighters because it can be used as a source of $O_2(g)$. In principle, $KO_2(s)$ can react with both major components of human breath, $H_2O(g)$ and $CO_2(g)$, to produce $O_2(g)$ and other products (all of which follow the expected patterns of reactivity we have seen). Predict the other products in these reactions and design experiments to determine whether $KO_2(s)$ does actually react with both $H_2O(g)$ and $CO_2(g)$.

(**c**) Propose an experiment to determine whether either of the reactions in part (b) is more important in the operation of a firefighter's breathing mask.

(**d**) The reaction of $K(s)$ and $O_2(g)$ leads to a mixture of $KO_2(s)$ and $K_2O(s)$. Use ideas presented in this exercise to design an experiment to determine the percentages of $KO_2(s)$ and $K_2O(s)$ in the product mixture that results from the reaction of $K(s)$ with excess $O_2(g)$.

8

BASIC CONCEPTS OF CHEMICAL BONDING

▲ **GIANT CRYSTALS.** These gypsum crystals, large enough for people to walk on, are composed of $CaSO_4 \cdot 2H_2O$. The ionic bonding between calcium and sulfate ions at the atomic scale leads to the characteristic crystal shape at the human scale.

Whenever two atoms or ions are strongly held together, we say there is a **chemical bond** between them. There are three general types of chemical bonds: *ionic, covalent*, and *metallic*. These three types of bonds are in the substances illustrated in **Figure 8.1**: table salt, water, and stainless steel.

Table salt is sodium chloride, NaCl, which consists of sodium ions, Na^+, and chloride ions, Cl^-. The structure is held together by **ionic bonds**, which are due to the electrostatic attractions between oppositely charged ions. Water consists mainly of H_2O molecules. The hydrogen and oxygen atoms are bonded to one another through **covalent bonds**, in which molecules are formed by the sharing of electrons between atoms. The spoon consists mainly of iron metal, in which Fe atoms are connected to one another by **metallic bonds**, which are formed by electrons that are relatively free to move from one atom to another. These different substances—NaCl, H_2O, and Fe metal—behave as they do because of the ways in which their constituent atoms are connected to one another. For example, NaCl readily dissolves in water, but Fe metal does not.

In this chapter and the next, we examine the relationship between the electronic structure of atoms and the ionic and covalent chemical bonds they form. We discuss metallic bonding in Chapter 12.

WHAT'S AHEAD

- 8.1 ▶ **Lewis Symbols and the Octet Rule** Learn about the three main types of chemical bonds: *ionic*, *covalent*, and *metallic.* In discussing bonding, *Lewis symbols* provide a useful shorthand for keeping track of valence electrons. We observe that atoms usually follow the *octet rule*.
- 8.2 ▶ **Ionic Bonding** Explore ionic substances, in which atoms are held together by the electrostatic attractions between ions of opposite charge. Analyze the energetics of forming ionic substances and describe the *lattice energy* of these substances.
- 8.3 ▶ **Covalent Bonding** Examine the bonding in molecular substances, in which atoms bond by sharing one or more electron pairs. In general, the electrons are shared in such a way that each atom attains an octet of electrons.
- 8.4 ▶ **Bond Polarity and Electronegativity** Learn that *electronegativity* is the ability of an atom in a compound to attract electrons to itself. In general, electron pairs are shared unequally between atoms with different electronegativities, leading to *polar covalent bonds*.
- 8.5 ▶ **Drawing Lewis Structures** Learn that *Lewis structures* are a simple yet powerful way of predicting covalent bonding patterns in molecules. In addition to the octet rule, see how the concept of *formal charge* can be used to identify the dominant Lewis structure.
- 8.6 ▶ **Resonance Structures** We see that, in some cases, more than one equivalent Lewis structure can be drawn for a molecule or polyatomic ion. The bonding description in such cases is a blend of two or more *resonance structures*.
- 8.7 ▶ **Exceptions to the Octet Rule** Recognize that the octet rule is more of a guideline than an absolute rule. Exceptions to the rule include molecules with an odd number of electrons, molecules where large differences in electronegativity prevent an atom from completing its octet, and molecules where an element from period 3 or below in the periodic table attains more than an octet of electrons.
- 8.8 ▶ **Strengths and Lengths of Single and Multiple Bonds** Observe that bond strengths and lengths vary with the number of shared electron pairs between a given atom pair.

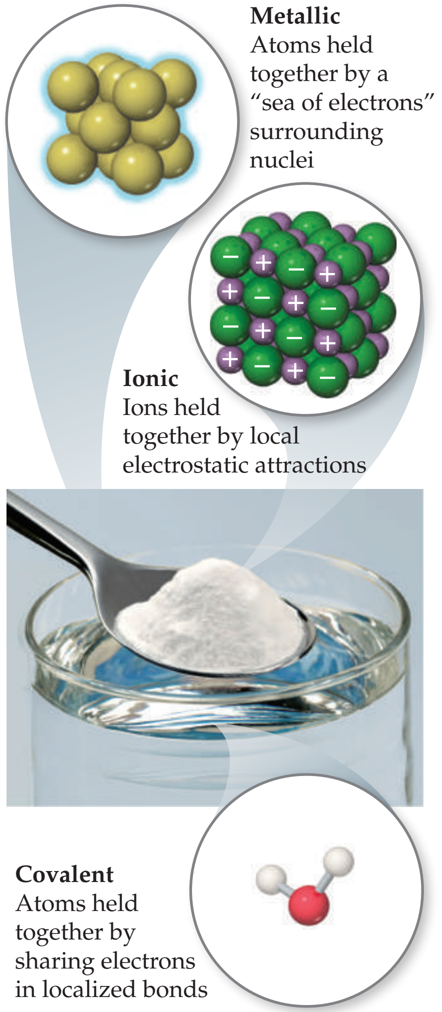
Learning Objective

When you finish Section 8.1, you should be able to:

- Draw Lewis symbols for atoms and use them to determine how many electrons an atom must lose or gain to obey the octet rule.

Go Figure

If the white powder were sugar, $C_{12}H_{22}O_{11}$, how would we have to change this picture?



Metallic
Atoms held together by a "sea of electrons" surrounding nuclei
Ionic
Ions held together by local electrostatic attractions
Covalent
Atoms held together by sharing electrons in localized bonds

▲ **Figure 8.1 Ionic, covalent, and metallic bonds.** The three different substances shown here are held together by different types of chemical bonds.

8.1 | Lewis Symbols and the Octet Rule

The electrons involved in chemical bonding are the *valence electrons*, which, for most atoms, are those in the outermost occupied shell. (Section 6.8) The American chemist G. N. Lewis (1875–1946) suggested a simple way of showing the valence electrons in an atom and tracking them during bond formation, using what are now known as either *Lewis electron-dot symbols* or simply Lewis symbols. The **Lewis symbol** for an element consists of the element's chemical symbol plus a dot for each valence electron. Sulfur, for example, has the electron configuration $[Ne]3s^23p^4$ and therefore six valence electrons. Its Lewis symbol is

The dots are placed on the four sides of the symbol—top, bottom, left, and right—and each side can accommodate up to two electrons. All four sides are equivalent, which means that the choice of sides for placement of two electrons rather than one electron is arbitrary. In general, we spread out the dots as much as possible. In the Lewis symbol for S, for instance, we prefer the dot arrangement shown rather than the arrangement having two electrons on three of the sides and none on the fourth.

The electron configurations and Lewis symbols for the main-group elements of periods 2 and 3 are shown in **Figure 8.2**. Notice that the number of valence electrons in any representative element is the same as the element's group number. For example, the Lewis symbols for oxygen and sulfur, members of group 6A, both show six dots.

The Octet Rule

Atoms often gain, lose, or share electrons to achieve the same number of electrons as the noble gas closest to them in the periodic table. The noble gases have very stable electron arrangements, as evidenced by their high ionization energies, low affinity for additional electrons, and general lack of chemical reactivity. (Section 7.8) Because all the noble gases except He have eight valence electrons, many atoms undergoing reactions end up with eight valence electrons. This observation has led to a guideline known as the **octet rule**: *Atoms tend to gain, lose, or share electrons until they are surrounded by eight valence electrons.*

An octet of electrons consists of full *s* and *p* subshells in an atom. In a Lewis symbol, an octet is shown as four pairs of valence electrons arranged around the element symbol, as in the Lewis symbols for Ne and Ar in Figure 8.2. There are exceptions to the octet rule, as we explain in Section 8.7, but it provides a useful framework for introducing many important concepts of bonding. The octet rule mostly applies to atoms that have *s* and *p* valence electrons; compounds of the transition metals, having valence *d* electrons, are examined in Chapter 23.

Self-Assessment Exercises

SAE 8.1 Which of the following is the most correct Lewis symbol for an oxygen atom?

(a) **(b)** **(c)** **(d)**

SAE 8.2 For each of the following Lewis symbols, indicate the group in the periodic table in which element Q belongs:

(i) **(ii)** **(iii)**

(a) i Group 1A, ii Group 5A, iii Group 3A **(b)** i Group 5A, ii Group 1A, iii Group 3A **(c)** i Group 0A, ii Group 3A, iii Group 1A **(d)** i Group 3A, ii Group 7A, iii Group 5A

8.2 | Ionic Bonding

Learning Objectives

When you finish Section 8.2, you should be able to:

- Analyze the factors that lead to the stability of ionic compounds.
- Order a series of ionic compounds from lowest to highest lattice energy.
- Use the octet rule to predict the preferred charges on ions.

Ionic substances generally result from the interaction of metals on the left side of the periodic table with nonmetals on the right side (excluding the noble gases, group 8A). In this section we look more closely at several aspects of the formation of ions and of ionic bonding.

When sodium metal, Na(*s*), is brought into contact with chlorine gas, $Cl_2(g)$, a violent reaction ensues (**Figure 8.3**). The product of this very exothermic reaction is sodium chloride, NaCl(*s*):

$$\mathrm{Na}(s) + \tfrac{1}{2}\mathrm{Cl}_2(g) \longrightarrow \mathrm{NaCl}(s) \qquad \Delta H_f^\circ = -410.9\ \mathrm{kJ} \qquad [8.1]$$

Sodium chloride is composed of Na^+ and Cl^- ions arranged in a three-dimensional array (**Figure 8.4**).

The formation of Na^+ from Na and Cl^- from Cl_2 indicates that an electron has been lost by a sodium atom and gained by a chlorine atom—we say there has been an *electron transfer* from the Na atom to the Cl atom. Two of the atomic properties discussed in Chapter 7 give us an indication of how readily electron transfer occurs: ionization energy, which shows how easily an electron can be removed from an atom; and electron affinity, which measures how much an atom wants to gain an electron. (Section 7.4) Electron transfer to form oppositely charged ions occurs when one atom readily gives up an electron (low ionization energy) and another atom readily gains an electron (high electron affinity). Thus, NaCl is a typical ionic compound because it consists of a metal of low ionization energy and a nonmetal of high electron affinity. Using Lewis electron-dot symbols (and showing a chlorine atom rather than the Cl_2 molecule), we can represent this reaction as

$$\mathrm{Na}\cdot + \cdot\ddot{\underset{\cdot\cdot}{\mathrm{Cl}}}: \longrightarrow \mathrm{Na}^+ + [:\ddot{\underset{\cdot\cdot}{\mathrm{Cl}}}:]^- \qquad [8.2]$$

The arrow indicates the transfer of an electron from the Na atom to the Cl atom. Each ion has an octet of electrons, the Na^+ octet being the $2s^22p^6$ electrons that lie below the single 3*s* valence electron of the Na atom. We have put a bracket around the chloride ion to emphasize that all eight electrons are located on it.

Ionic substances possess several characteristic properties. They are usually brittle substances with high melting points. They are usually crystalline. Furthermore, ionic crystals often can be cleaved; that is, they break apart along smooth, flat surfaces. These

Energetics of Ionic Bond Formation

The formation of sodium chloride from sodium and chlorine is *very* exothermic, as indicated by the large negative enthalpy of formation value given in Equation 8.1, $\Delta H_f^\circ = -410.9$ kJ. Appendix C shows that the heat of formation of other ionic substances is also quite negative. What factors make the formation of ionic compounds so exothermic?

In Equation 8.2, we represented the formation of NaCl as the transfer of an electron from Na to Cl. Recall from Section 7.4 that the loss of electrons from an atom is always an endothermic process. The energy needed to remove an electron from $Na(g)$ to form $Na^+(g)$ is the first ionization energy of Na, 496 kJ/mol. Recall that when a nonmetal gains an electron, the process is generally exothermic: The energy change when an electron is added to $Cl(g)$ is the electron affinity of Cl, −349 kJ/mol., where the negative sign indicates that energy is released in the process. (Section 7.4) From these energies, we can see that the transfer of an electron from an Na atom to a Cl atom would not be exothermic—the overall process would be an endothermic process that requires $496 - 349 = 147$ kJ/mol. This endothermic process corresponds to the formation of gaseous sodium and chloride ions that are infinitely far apart; in other words, the positive energy change assumes that the ions do not interact with each other, which is quite different from the situation in ionic solids.

The principal reason ionic compounds are stable is the electrostatic attraction between ions of opposite charge. This attraction draws the ions together, releasing energy and leads to the formation of a crystalline solid with a repeating pattern of cations and anions, such as that shown in Figure 8.4. A measure of how much stabilization results from arranging oppositely charged ions in an ionic solid is given by the **lattice energy**, which is *the energy required to completely separate one mole of a solid ionic compound into its gaseous ions*.

To envision this process for NaCl, imagine that the structure in Figure 8.4 expands from within, so that the distances between the ions increase until the ions are very far apart. This process requires 788 kJ/mol, which is the value of the lattice energy:

$$\mathrm{NaCl}(s) \longrightarrow \mathrm{Na}^+(g) + \mathrm{Cl}^-(g) \qquad \Delta H_{\mathrm{lattice}} = +788\ \mathrm{kJ/mol} \tag{8.3}$$

This process is highly endothermic, so the reverse process—the coming together of $Na^+(g)$ and $Cl^-(g)$ to form $NaCl(s)$—is highly exothermic ($\Delta H = -788$ kJ/mol).

Table 8.1 lists the lattice energies for a number of ionic compounds. The large positive values indicate that the ions are strongly attracted to one another in ionic solids. The energy released by the attraction between ions of unlike charge more than makes

TABLE 8.1 Lattice Energies for Some Ionic Compounds

Compound	Lattice Energy (kJ/mol)	Compound	Lattice Energy (kJ/mol)
LiF	1030	$MgCl_2$	2326

CsI	600		

up for the endothermic nature of ionization energies, making the formation of ionic compounds an exothermic process. The strong attractions also cause most ionic materials to be hard and brittle with high melting points; NaCl, for example, melts at 801 °C.

The magnitude of the lattice energy of an ionic solid depends on the charges of the ions, their sizes, and their arrangement in the solid. We saw in Section 5.1 that the electrostatic potential energy of two interacting charged particles is given by:

$$E_{\mathrm{el}} = \frac{\kappa Q_1 Q_2}{d} \qquad [8.4]$$

In this equation Q_1 and Q_2 are the charges on the particles in coulombs, including their signs; d is the distance between their centers in meters; and κ is a constant, 8.99×10^9 J-m/C^2. From Equation 8.4 we can see that the attractive interaction between two oppositely charged ions increases as the magnitudes of their charges increase and as the distance between their centers decreases. Thus, *for a given arrangement of ions, the lattice energy increases as the charges on the ions increase and as their radii decrease*. The variation in the magnitude of lattice energies depends more on ionic charge than on ionic radius because ionic radii vary over only a limited range compared to charges.

Sample Exercise 8.1

Magnitudes of Lattice Energies

Without consulting Table 8.1, arrange the ionic compounds NaF, CsI, and CaO in order of increasing lattice energy.

SOLUTION

Analyze From the formulas for three ionic compounds, we must determine their relative lattice energies.

Plan We need to determine the charges and relative sizes of the ions in the compounds. We then use Equation 8.4 qualitatively to determine the relative energies, knowing that (**a**) the larger the ionic charges, the greater the energy and (**b**) the farther apart the ions are, the lower the energy.

Solve NaF consists of Na^+ and F^- ions, CsI of Cs^+ and I^- ions, and CaO of Ca^{2+} and O^{2-} ions. Because the product Q_1Q_2 appears in the numerator of Equation 8.4, the lattice energy increases dramatically when the magnitudes of the charges increase. Thus, we expect the lattice energy of CaO, which has 2+ and 2− ions, to be the greatest of the three.

The ionic charges are the same in NaF and CsI. The difference in their lattice energies thus depends on the difference in the distance between ions in the lattice. Because ionic size increases as we go down a group in the periodic table (Section 7.3), we know that Cs^+ is larger than Na^+ and I^- is larger than F^-. Therefore, the distance between Na^+ and F^- ions in NaF is less than the distance between the Cs^+ and I^- ions in CsI. As a result, the lattice energy of NaF should be greater than that of CsI. In order of increasing energy, therefore, we have CsI $<$ NaF $<$ CaO.

Check Table 8.1 confirms our predicted order is correct.

Practice Exercise

Which substance do you expect to have the greatest lattice energy: MgF_2, CaF_2, or ZrO_2?

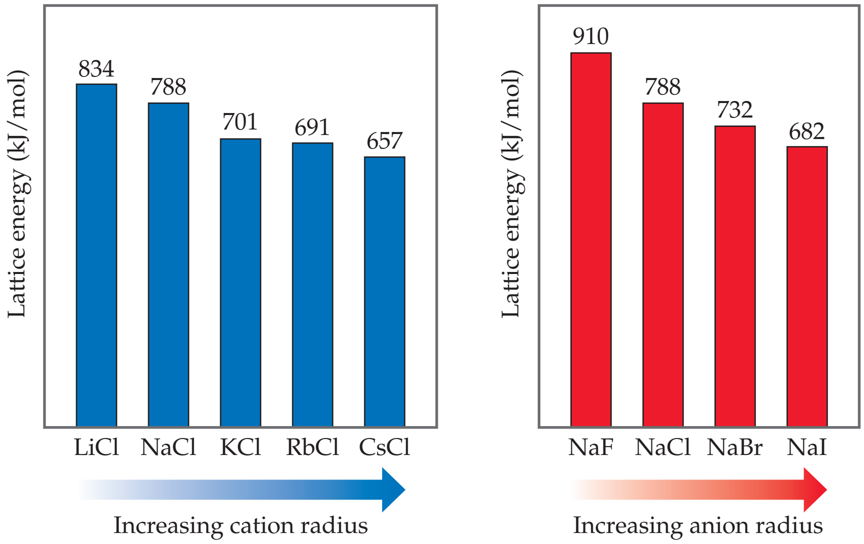
Because lattice energy decreases as distance between ions increases, lattice energies follow trends that parallel those in ionic radius shown in Figure 7.8. In particular, because ionic radius increases as we go down a group of the periodic table, we find that, for a given type of ionic compound, lattice energy decreases as we go down a group. **Figure 8.5** illustrates this trend for the alkali chlorides MCl (M = Li, Na, K, Rb, Cs) and the sodium halides NaX(X = F, Cl, Br, I).

Electron Configurations of Ions of the *s*- and *p*-Block Elements

The energetics of ionic bond formation helps explain why many ions tend to have noble-gas electron configurations. For example, sodium readily loses one electron to form Na^+, which has the same electron configuration as Ne:

$$\begin{array}{lll} \mathrm{Na} & 1s^22s^22p^63s^1 & = [\mathrm{Ne}]3s^1 \\ \mathrm{Na}^+ & 1s^22s^22p^6 & = [\mathrm{Ne}] \end{array}$$

Go Figure Using this figure, predict the lattice energy of KF to one significant figure.



▲ **Figure 8.5 Periodic trends in lattice energy as a function of cation or anion radius.**

Even though lattice energy increases with increasing ionic charge, we never find ionic compounds that contain Na^{2+} ions. The second electron removed would have to come from an inner shell of the sodium atom, and removing electrons from an inner shell requires a very large amount of energy. (Section 7.4) The increase in lattice energy is not enough to compensate for the energy needed to remove an inner-shell electron. Thus, sodium and the other group 1A metals are found in ionic substances only as 1+ ions.

Similarly, adding electrons to nonmetals is either exothermic or only slightly endothermic as long as the electrons are added to the valence shell. Thus, a Cl atom readily adds an electron to form Cl^-, which has the same electron configuration as Ar:

$$\text{Cl} \qquad 1s^22s^22p^63s^23p^5 = [\text{Ne}]3s^23p^5$$

$$\text{Cl}^- \qquad 1s^22s^22p^63s^23p^6 = [\text{Ne}]3s^23p^6 = [\text{Ar}]$$

To form a Cl^{2-} ion, the second electron would have to be added to the next higher shell of the Cl atom, an addition that is energetically very unfavorable. Therefore, we never observe Cl^{2-} ions in ionic compounds. We thus expect ionic compounds of the representative metals from groups 1A, 2A, and 3A to contain 1+, 2+, and 3+ cations, respectively, and we usually expect ionic compounds of the representative nonmetals of groups 5A, 6A, and 7A to contain 3−, 2−, and 1− anions, respectively.

Transition-Metal Ions

We have seen that the octet rule is a useful tool for predicting the preferred ionic charges of many ions of the representative elements. It is less useful as a guide to predict the charges on ions formed by atoms of the transition elements. Consider an Fe atom, for example, which has an electron configuration of $[\text{Ar}]4s^23d^6$. (Section 6.9) Fe forms two common cations, Fe^{2+} and Fe^{3+}, which have electron configurations of $[\text{Ar}]3d^6$ and $[\text{Ar}]3d^5$, respectively. (Sections 2.8 and 7.4) Neither Fe^{2+} nor Fe^{3+} has an octet of electrons, nor is there a simple analogy to allow us to predict these as the preferred ionic charges.

The octet rule, though useful, is clearly limited in scope and is generally not useful for transition metals. That said, once we know the charge on a transition metal ion, we can predict the way it will combine with nonmetals to make ionic compounds. For example, both Fe^{2+} and Fe^{3+} form oxides—namely, FeO and Fe_2O_3, respectively. Consistent with our expectations for ionic substances, both FeO and Fe_2O_3 are brittle solids with high melting points.

A CLOSER LOOK Calculation of Lattice Energies: The Born–Haber Cycle

Lattice energies cannot be determined directly by experiment. They can, however, be calculated by envisioning the formation of an ionic compound as occurring in a series of well-defined steps. We can then use Hess's law (Section 5.6) to combine the steps in a way that gives the lattice energy for the compound. By so doing, we construct a **Born–Haber cycle**, a thermochemical cycle named after the German scientists Max Born (1882–1970) and Fritz Haber (1868–1934), who introduced it to analyze the factors contributing to the stability of ionic compounds.

Let's use NaCl as an example. In Equation 8.3, which defines lattice energy, NaCl(*s*) is the reactant, and the gas-phase ions $Na^+(g)$ and $Cl^-(g)$ are the products. This equation is our target as we apply Hess's law.

In seeking a set of other equations that can be added up to give our target equation, we can use the heat of formation for NaCl (Section 5.7):

$$Na(s) + \tfrac{1}{2}Cl_2(g) \longrightarrow NaCl(s) \qquad \Delta H_f^\circ[NaCl(s)] = -411\text{ kJ} \qquad [8.5]$$

This equation must be turned around, however, so that we have NaCl(*s*) as the reactant as we do in the equation for the lattice energy. We can use two other equations to arrive at our target, as shown below:

$$\begin{aligned}
&1.\ NaCl(s) \longrightarrow Na(s) + \tfrac{1}{2}Cl_2(g) && \Delta H_1 = -\Delta H_f^\circ[NaCl(s)] \\
& && = +411\text{ kJ} \\
&2.\ Na(s) \longrightarrow Na^+(g) + e^- && \Delta H_2 = ? \\
&3.\ e^- + \tfrac{1}{2}Cl_2(g) \longrightarrow Cl^-(g) && \Delta H_3 = ? \\
\hline
&4.\ NaCl(s) \longrightarrow Na^+(g) + Cl^-(g) && \Delta H_4 = \Delta H_1 + \Delta H_2 + \Delta H_3 \\
& && = \Delta H_{\text{lattice}}
\end{aligned}$$

Step 2 involves the formation of sodium ion from solid sodium, which is just the heat of formation for sodium gas and the first ionization energy for sodium (Appendix C and Figure 7.11 list numbers for these processes):

$$Na(s) \longrightarrow Na(g) \qquad \Delta H = \Delta H_f^\circ[Na(g)] = 108\text{ kJ} \qquad [8.6]$$

$$Na(g) \longrightarrow Na^+(g) + e^- \qquad \Delta H = I_1(Na) = 496\text{ kJ} \qquad [8.7]$$

The sum of these two processes gives us the required energy for Step 2 (above), which is 604 kJ.

Similarly, for Step 3, we have to create chlorine atoms, and then anions, from the Cl_2 molecule, in two steps. The enthalpy changes for these two steps are the sum of the enthalpy of formation of Cl(*g*) and the electron affinity of chlorine, *EA*(Cl):

$$\tfrac{1}{2}Cl_2(g) \longrightarrow Cl(g) \qquad \Delta H = \Delta H_f^\circ[Cl(g)] = 122\text{ kJ} \qquad [8.8]$$

$$e^- + Cl(g) \longrightarrow Cl^-(g) \qquad \Delta H = EA(Cl) = -349\text{ kJ} \qquad [8.9]$$

The sum of these two processes gives us the required energy for Step 3 (above), which is −227 kJ.

Finally, when we put it all together, we have:

$$\begin{aligned}
&1.\ NaCl(s) \longrightarrow Na(s) + \tfrac{1}{2}Cl_2(g) && \Delta H_1 = -\Delta H_f^\circ[NaCl(s)] \\
& && = +411\text{ kJ} \\
&2.\ Na(s) \longrightarrow Na^+(g) + e^- && \Delta H_2 = 604\text{ kJ} \\
&3.\ e^- + \tfrac{1}{2}Cl_2(g) \longrightarrow Cl^-(g) && \Delta H_3 = -227\text{ kJ} \\
\hline
&4.\ NaCl(s) \longrightarrow Na^+(g) + Cl^-(g) && \Delta H_4 = 788\text{ kJ} = \Delta H_{\text{lattice}}
\end{aligned}$$

This process is described as a "cycle" because it corresponds to the scheme in **Figure 8.6**, which shows how all the quantities we have just calculated are related. The sum of all the blue "up" arrow energies has to be equal to the sum of all the red "down" arrow energies in this cycle. Born and Haber recognized that if we know the value of every quantity in the cycle except the lattice energy, we can calculate it from this cycle.

Sample Exercise 8.2

Charges on Ions

Predict the ion generally formed by **(a)** Sr, **(b)** S, **(c)** Al.

SOLUTION

Analyze We must decide how many electrons are most likely to be gained or lost by atoms of Sr, S, and Al.

Plan In each case, we can use the element's position in the periodic table to predict whether the element forms a cation or an anion. We can then use its electron configuration to determine the most likely ion formed.

Solve

(a) Strontium is a metal in group 2A, so it forms a cation. Its electron configuration is $[Kr]5s^2$, and so we expect that the two valence electrons will be lost to give an Sr^{2+} ion.

(b) Sulfur is a nonmetal in group 6A, so it will tend to be found as an anion. Its electron configuration ($[Ne]3s^23p^4$) is two electrons short of a noble-gas configuration. Thus, we expect that sulfur will form S^{2-} ions.

(c) Aluminum is a metal in group 3A. We therefore expect it to form Al^{3+} ions.

Check The ionic charges we predict here are confirmed in Tables 2.4 and 2.5.

▶ Practice Exercise

Predict the charges on the ions formed when magnesium reacts with nitrogen.

Self-Assessment Exercises

SAE 8.3 Which of the following statements about ions and ionic bonding is or are *true*?

- **(i)** An atom with a low first ionization energy and low electron affinity is more likely to form a cation than an anion.
- **(ii)** The most common ion for an atom of a representative element generally adopts a noble-gas electron configuration.
- **(iii)** The stability of KBr is due to the electrostatic attraction between the potassium ions and the bromide ions.

(**a**) Only one of the statements is true. (**b**) i and ii are true. (**c**) i and iii are true. (**d**) ii and iii are true. (**e**) All three statements are true.

SAE 8.4 Which of the following statements about ionic bonding is *false*? (**a**) Ionic bonds are found in compounds formed from metals combined with nonmetals. (**b**) The attraction between cations and anions increases as the charges on the ions increase. (**c**) The attraction between cations and anions increases as the radii of the ions increase. (**d**) Lattice energy is the energy needed to break an ionic compound into gaseous ions.

SAE 8.5 Place the following ionic substances in order from smallest to largest lattice energy: CaO, CsI, KF, KI, MgO. (**a**) CsI < KI < KF < CaO < MgO (**b**) CaO < MgO < CsI < KI < KF (**c**) KF < KI < CsI < MgO < CaO (**d**) CsI < CaO < KF < KI < MgO (**e**) KI < CsI < CaO < MgO < KF

SAE 8.6 Which of the following is the electron configuration of the most common ion of a P atom? (**a**) [Ne]$3s^23p^3$ (**b**) [Ne]$3s^2$ (**c**) $1s^22s^22p^6$ (**d**) [Ne]$3s^23p^6$ (**e**) [Ne]$3s^23p^33d^3$

8.3 | Covalent Bonding

Learning Objectives

When you finish Section 8.3, you should be able to:

- ▶ Describe covalent bonding and differentiate it from ionic bonding.
- ▶ Draw Lewis structures to represent the distribution of electrons in molecules.
- ▶ Use Lewis structures and the octet rule to predict the presence and location of multiple bonds in molecules.

The vast majority of chemical substances do not have the characteristics of ionic materials. Most of the substances with which we come into daily contact—such as water—tend to be gases, liquids, or solids with low melting points. Many, such as gasoline, vaporize readily. Many are pliable in their solid forms—for example, plastic bags and wax.

For the very large class of substances that do not behave like ionic substances, we need a different model to describe the bonding between atoms. G. N. Lewis reasoned that atoms might acquire a noble-gas electron configuration by sharing electrons with other atoms. A chemical bond formed by sharing a pair of electrons is a *covalent bond*. The hydrogen molecule, H_2, provides the simplest example of a covalent bond. When two hydrogen atoms are close to each other, the two positively charged nuclei repel each other, the two negatively charged electrons repel each other, and the nuclei and electrons attract each other, as shown in **Figure 8.7(a)**. Because the molecule is stable, we know that the attractive forces must overcome the repulsive ones. Let's take a closer look at the attractive forces that hold H_2 together.

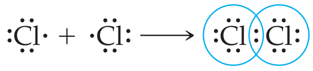
By using quantum-mechanical methods analogous to those applied to atoms in Section 6.5, we can calculate the distribution of electron density in molecules. Such a calculation for H_2 shows that the attractions between the nuclei and the electrons cause electron density to concentrate between the nuclei, as shown in Figure 8.7(b). As a result, the overall electrostatic interactions are attractive. Thus, the atoms in H_2 are held together principally because the two positive nuclei are attracted to the concentration of negative charge between them. In essence, the shared pair of electrons in any covalent bond acts as a kind of "glue" to bind atoms together.

Lewis Structures

The formation of covalent bonds can be represented with Lewis symbols. The formation of the H_2 molecule from two H atoms, for example, can be represented as

In forming the covalent bond, each hydrogen atom acquires a second electron, achieving the stable, two-electron, noble-gas electron configuration of helium.

Formation of a covalent bond between two Cl atoms to give a Cl_2 molecule can be represented in a similar way:

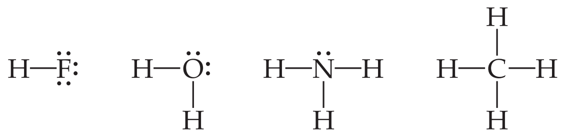


By sharing the bonding electron pair, each chlorine atom has eight electrons (an octet) in its valence shell, thus achieving the noble-gas electron configuration of argon.

The structures shown here for H_2 and Cl_2 are **Lewis structures**, or *Lewis dot structures*. While these structures show circles to indicate electron sharing, the more common convention is to show each shared electron pair or **bonding pair**, as a line and any unshared electron pairs (also called **lone pairs** or **nonbonding pairs**) as dots. Written this way, the Lewis structures for H_2 and Cl_2 are

$$\mathrm{H{-}H} \qquad :\!\underset{\cdot\cdot}{\overset{\cdot\cdot}{\mathrm{Cl}}}{-}\underset{\cdot\cdot}{\overset{\cdot\cdot}{\mathrm{Cl}}}\!:$$

For nonmetals, the number of valence electrons in a neutral atom is the same as the group number. Therefore, one might predict that 7A elements, such as F, would form one covalent bond to achieve an octet; 6A elements, such as O, would form two covalent bonds; 5A elements, such as N, would form three; and 4A elements, such as C, would form four. These predictions are borne out in many compounds, as in, for example, the compounds with hydrogen of the nonmetals of the second row of the periodic table:



$$\mathrm{H{-}}\underset{\cdot\cdot}{\overset{\cdot\cdot}{\mathrm{F}}}\!: \qquad \mathrm{H{-}}\overset{\cdot\cdot}{\underset{|\atop \mathrm{H}}{\mathrm{O}}}\!: \qquad \mathrm{H{-}}\overset{\cdot\cdot}{\underset{|\atop \mathrm{H}}{\mathrm{N}}}\mathrm{{-}H} \qquad \mathrm{H{-}}\overset{\mathrm{H}\atop |}{\underset{|\atop \mathrm{H}}{\mathrm{C}}}\mathrm{{-}H}$$

Multiple Bonds

A shared electron pair constitutes a single covalent bond, generally referred to simply as a **single bond**. In many molecules, atoms attain complete octets by sharing more than one pair of electrons. When two electron pairs are shared by two atoms, two lines are drawn in the Lewis structure, representing a **double bond**. In carbon dioxide, for example, bonding occurs between carbon, with four valence electrons, and oxygen, with six:

$$:\!\underset{\cdot}{\overset{\cdot\cdot}{\mathrm{O}}}\!: + \cdot\underset{\cdot}{\overset{\cdot}{\mathrm{C}}}\cdot + :\!\underset{\cdot}{\overset{\cdot\cdot}{\mathrm{O}}}\!: \longrightarrow \underset{\cdot\cdot}{\overset{\cdot\cdot}{\mathrm{O}}}\!::\!\mathrm{C}\!::\!\underset{\cdot\cdot}{\overset{\cdot\cdot}{\mathrm{O}}} \qquad (\text{or } \underset{\cdot\cdot}{\overset{\cdot\cdot}{\mathrm{O}}}{=}\mathrm{C}{=}\underset{\cdot\cdot}{\overset{\cdot\cdot}{\mathrm{O}}})$$

As the diagram shows, each oxygen atom acquires an octet by sharing two electron pairs with carbon. In the case of CO_2, carbon acquires an octet by sharing two electron pairs with each of the two oxygen atoms; each double bond involves four electrons.

A **triple bond** corresponds to the sharing of three pairs of electrons, such as in the N_2 molecule:

$$:\!\underset{\cdot}{\overset{\cdot}{\mathrm{N}}}\cdot + \cdot\underset{\cdot}{\overset{\cdot}{\mathrm{N}}}\!: \longrightarrow :\!\mathrm{N}\!:::\!\mathrm{N}\!: \qquad (\text{or } :\!\mathrm{N}{\equiv}\mathrm{N}\!:)$$

Because each nitrogen atom has five valence electrons, three electron pairs must be shared to achieve the octet configuration.

The properties of N_2 are in complete accord with its Lewis structure. Nitrogen is a diatomic gas with exceptionally low reactivity that results from the very stable nitrogen–nitrogen bond. The nitrogen atoms are separated by only 1.10 Å. The short separation distance between the two N atoms is a result of the triple bond between the atoms. From studies of the structures of many different substances in which nitrogen atoms share one or two electron pairs, we have learned that the average distance between bonded nitrogen atoms varies with the number of shared electron pairs:

N—N	N═N	N≡N
1.47 Å	1.24 Å	1.10 Å

As a general rule, the length of the bond between two atoms decreases as the number of shared electron pairs increases. We explore this point in greater detail in Section 8.8.

Go Figure

What would happen to the concentration of electron density between the nuclei in (b) if you pulled the nuclei farther apart?

Sample Exercise 8.3

Lewis Structure of a Compound

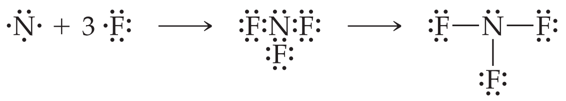
Given the Lewis symbols for nitrogen and fluorine in Figure 8.2, predict the formula of the stable binary compound (a compound composed of two elements) formed when nitrogen reacts with fluorine and draw its Lewis structure.

SOLUTION

Analyze According to the Lewis symbols for nitrogen and fluorine, nitrogen has five valence electrons and fluorine has seven.

Plan We need to find a combination of the two elements that results in an octet of electrons around each atom. Nitrogen requires three additional electrons to complete its octet, and fluorine requires one. Sharing a pair of electrons between one N atom and one F atom will result in an octet of electrons for fluorine but not for nitrogen. We therefore need to figure out a way to get two more electrons for the N atom.

Solve Nitrogen must share a pair of electrons with three fluorine atoms to complete its octet. Thus, the binary compound these two elements form must be NF_3:



Check The Lewis structure in the center shows that each atom is surrounded by an octet of electrons. Once you are accustomed to thinking of each line in a Lewis structure as representing *two* electrons, you can just as easily use the structure on the right to check for octets.

Practice Exercise

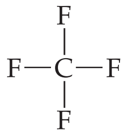
Compare the Lewis structure for water, H_2O, with that for methane, CH_4. How many valence electrons are in each structure? How many bonding pairs and how many nonbonding pairs does each structure have?

Self-Assessment Exercises

SAE 8.7 The CF_4 molecule has a central C atom bonded to four F atoms, as shown in the figure. Which of the following statements about the CF_4 molecule is or are *true*?

- **(i)** The electrons in the C—F bonds are attracted to both the C and F nuclei.
- **(ii)** The correct Lewis structure of CF_4 has four bonding pairs of electrons and no nonbonding pairs.
- **(iii)** Every atom in the CF_4 molecule satisfies the octet rule.

(**a**) Only one of the statements is true. (**b**) i and ii are true. (**c**) i and iii are true. (**d**) ii and iii are true. (**e**) All three statements are true.



SAE 8.8 Which of the following statements about multiple bonds is *false*? (**a**) A double bond is shorter than a single bond. (**b**) A triple bond involves the sharing of three electrons between the two atoms. (**c**) The formation of multiple bonds allows atoms to satisfy the octet rule. (**d**) A molecule can have more than one multiple bond in it.

8.4 | Bond Polarity and Electronegativity

Learning Objectives

When you finish Section 8.4, you should be able to:

- Describe the concept of electronegativity and its periodic trends.
- Categorize different types of bonds based on the electronegativity difference of the two bonded atoms.
- Relate the dipole moment of a diatomic molecule to the partial charges on its atoms.
- Differentiate compounds that possess ionic bonds from those that possess covalent bonds based on their physical properties.

When two identical atoms bond, as in Cl_2 or H_2, the electron pairs must be shared equally. When two atoms from opposite sides of the periodic table bond, such as NaCl, there is relatively little sharing of electrons, which means that NaCl is best described as an ionic compound composed of Na^+ and Cl^- ions. The 3*s* electron of the Na atom is, in effect, transferred completely to chlorine. The bonds that are found in most substances fall somewhere between these extremes. In this section, we look more closely at bonds in which electrons are shared unequally between the two atoms.

When discussing the degree of sharing of electrons between two atoms in a bond, it is helpful to introduce some new terminology. **Bond polarity** is a measure of how equally or unequally the electrons in any covalent bond are shared. A **nonpolar covalent bond** is one in which the electrons are shared equally, as in Cl_2 and N_2. In a **polar covalent bond**, one of the atoms exerts a greater attraction for the bonding electrons than the other. If the difference in relative ability to attract electrons is large enough, an ionic bond is formed.

Electronegativity

We use a quantity called *electronegativity* to estimate whether a given bond is nonpolar covalent, polar covalent, or ionic:

> **Electronegativity** is defined as the ability of an atom *in a molecule* to attract electrons to itself.

The greater an atom's electronegativity, the greater its ability to attract electrons to itself. The electronegativity of an atom in a molecule is related to the atom's ionization energy and electron affinity, which are properties of isolated atoms. An atom with a very negative electron affinity and a high ionization energy both attracts electrons from other atoms and resists having its electrons attracted away; therefore, it is highly electronegative.

Electronegativity values can be based on a variety of properties, not just ionization energy and electron affinity. The American chemist Linus Pauling (1901–1994) developed the first and most widely used electronegativity scale, which is based on thermochemical data. In the Pauling scale, electronegativity values range from 0.7 to 4.0, with no units. As **Figure 8.8** shows, there is generally an increase in electronegativity from left to right across a period—that is, from the most metallic to the most nonmetallic elements. With some exceptions (especially in the transition metals), electronegativity decreases from top to bottom in a group. This is what we expect because ionization energies decrease as we go down a group and electron affinities do not change very much.

You do not need to memorize electronegativity values. Instead, you should know the periodic trends so that you can predict which of two elements is more electronegative.

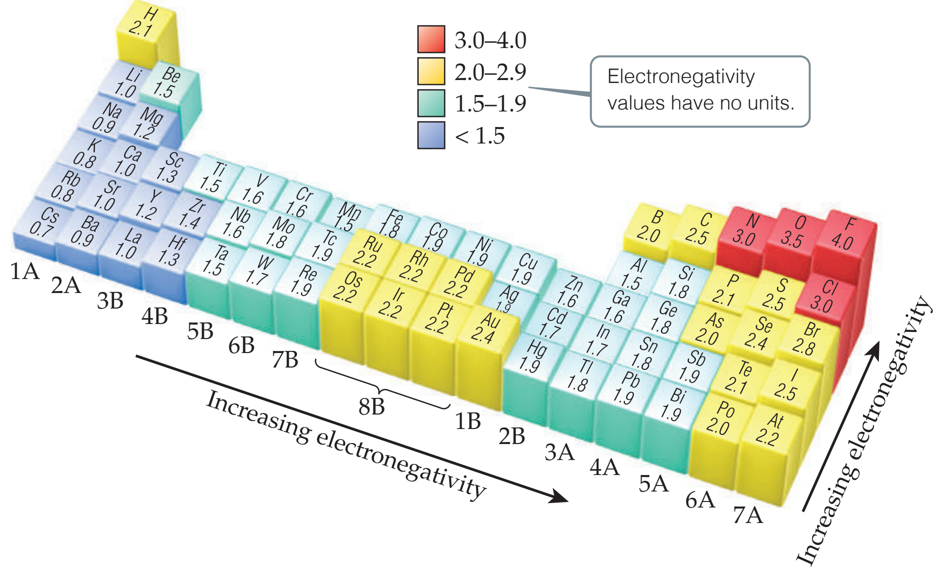
Electronegativity and Bond Polarity

We can use the difference in electronegativity between two atoms to gauge the polarity of the bond the atoms form. Consider these three fluorine-containing compounds:

	F_2	HF	LiF
Electronegativity difference	$4.0 - 4.0 = 0$	$4.0 - 2.1 = 1.9$	$4.0 - 1.0 = 3.0$
Type of bond	Nonpolar covalent	Polar covalent	Ionic

Go Figure

For the group 6A elements, what is the trend in electronegativity with increasing atomic number?



Electronegativity values have no units.

▲ **Figure 8.8 Electronegativity values based on Pauling's thermochemical data.** Notice the general increase in values from left to right across a period, and the general decrease from top to bottom down a group.

In F_2 the electrons are shared equally between the fluorine atoms and, thus, the covalent bond is *nonpolar*. A nonpolar covalent bond results when the electronegativities of the bonded atoms are equal.

In HF the fluorine atom has a greater electronegativity than the hydrogen atom, with the result that the electrons are shared unequally—the bond is *polar*. In general, a polar covalent bond results when the atoms differ in electronegativity. In HF the more electronegative fluorine atom attracts electron density away from the less electronegative hydrogen atom, leaving a partial positive charge on the hydrogen atom and a partial negative charge on the fluorine atom. We can represent this charge distribution as

$$\overset{\delta+}{\mathrm{H}}-\overset{\delta-}{\mathrm{F}}$$

The $\delta+$ and $\delta-$ (read "delta plus" and "delta minus") symbolize the partial positive and negative charges, respectively. In a polar bond, these values are less than the full charges of the ions.

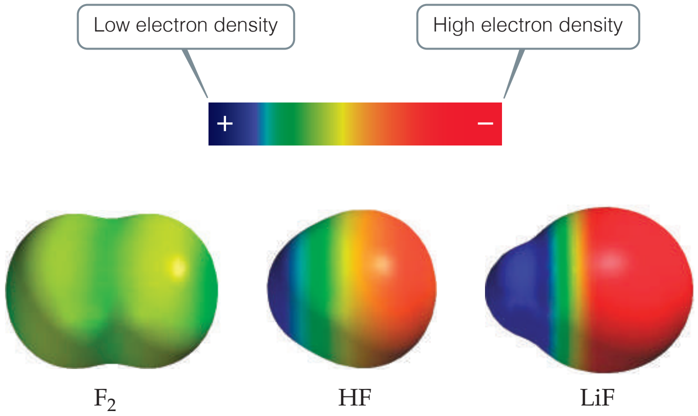
In LiF the electronegativity difference is very large, meaning that the electron density is shifted far toward F. The resulting bond is therefore most accurately described as *ionic*. Thus, if we considered the bond in LiF to be fully ionic, we could say $\delta+$ for Li is $1+$ and $\delta-$ for F is $1-$. If the electronegativity difference between two atoms is greater than 2.0, we generally consider a bond between these two atoms to be an ionic bond.

The shift of electron density toward the more electronegative atom in a bond can be seen from the results of calculations of electron-density distributions. For the three species in our example, the calculated electron-density distributions are shown in **Figure 8.9**. Notice that the distribution in F_2 is symmetrical, whereas the electron density in HF is clearly shifted toward fluorine, and in LiF the shift is even greater. These examples illustrate, therefore, that *the greater the difference in electronegativity between two atoms, the more polar their bond*.

Dipole Moments

The difference in electronegativity between H and F leads to a polar covalent bond in the HF molecule. As a consequence, there is a concentration of negative charge on the more electronegative F atom, leaving the less electronegative H atom at the positive end of the molecule. A molecule such as HF, in which the centers of positive and negative charge do

Go Figure If an electron-density distribution has a blue side to it, what can you conclude about the partial charge on that atom?



▲ **Figure 8.9 Electron-density distribution.** This computer-generated rendering shows the calculated electron-density distribution on the surface of the F_2, HF, and LiF molecules.

Sample Exercise 8.4

Bond Polarity

In each case, which bond is more polar? (**a**) B—Cl or C—Cl, (**b**) P—F or P—Cl. Indicate in each case which atom has the partial negative charge.

SOLUTION

Analyze We are asked to determine relative bond polarities, given nothing but the atoms involved in the bonds.

Plan Because we are not asked for quantitative answers, we can use the periodic table and our knowledge of electronegativity trends to answer the question.

Solve

(**a**) The chlorine atom is common to both bonds. Therefore, we just need to compare the electronegativities of B and C. Because boron is to the left of carbon in the periodic table, we predict that boron has the lower electronegativity. Chlorine, being on the right side of the table, has high electronegativity. The more polar bond will be the one between the atoms with the biggest differences in electronegativity. Consequently, the B—Cl bond is more polar; the chlorine atom carries the partial negative charge because it has a higher electronegativity.

(**b**) In this example, phosphorus is common to both bonds, and so we just need to compare the electronegativities of F and Cl. Because fluorine is above chlorine in the periodic table, it should be more electronegative and will form the more polar bond with P. The higher electronegativity of fluorine means that it will carry the partial negative charge.

Check

(**a**) Using Figure 8.8: The difference in the electronegativities of chlorine and boron is $3.0 - 2.0 = 1.0$; the difference between the electronegativities of chlorine and carbon is $3.0 - 2.5 = 0.5$. Hence, the B—Cl bond is more polar, as we had predicted.

(**b**) Using Figure 8.8: The difference in the electronegativities of chlorine and phosphorus is $3.0 - 2.1 = 0.9$; the difference between the electronegativities of fluorine and phosphorus is $4.0 - 2.1 = 1.9$. Hence, the P—F bond is more polar, as we had predicted.

Practice Exercise

Which of the following bonds is most polar: S—Cl, S—Br, Se—Cl, or Se—Br?

not coincide, is a **polar molecule**. Thus, we describe both bonds and entire molecules as being polar and nonpolar.

We can indicate the polarity of the HF molecule in two ways:

$$\overset{\delta+}{\text{H}}-\overset{\delta-}{\text{F}} \quad or \quad \overset{+\!\!\!\longrightarrow}{\text{H}-\text{F}}$$

In the notation on the right, the arrow denotes the shift in electron density toward the fluorine atom. The crossed end of the arrow can be thought of as a plus sign designating the positive end of the molecule.

Polarity helps determine many properties we observe at the macroscopic level in the laboratory and in everyday life. Polar molecules align themselves with respect to one another, with the negative end of one molecule and the positive end of another attracting each other. Polar molecules are likewise attracted to ions. The negative end of a polar molecule is attracted to a positive ion, whereas the positive end is attracted to a negative ion. These interactions account for many properties of liquids, solids, and solutions, as we explore in Chapters 11, 12, and 13. Charge separation within molecules plays an important role in energy conversion processes such as photosynthesis and in solar cells.

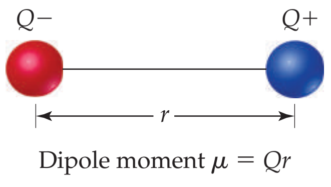
How can we quantify the polarity of a molecule? Whenever two electrical charges of equal magnitude but opposite sign are separated by a distance, a **dipole** is established. The quantitative measure of the magnitude of a dipole is called its **dipole moment**, denoted with the Greek letter mu, μ. The dipole moment is what we call a *vector* quantity, meaning that it has both a magnitude and a direction. The direction of a dipole moment is given by the "crossed arrow" that we used previously to describe the polarity of HF. The magnitude of the dipole moment depends on how much charge is separated and the distance of the separation. If two equal and opposite charges Q+ and Q− are separated by a distance *r*, as in **Figure 8.10**, the magnitude of the dipole moment is the product of Q and *r*:

$$\mu = Qr \qquad [8.10]$$

This expression tells us that the dipole moment increases as the magnitude of Q increases and as *r* increases. The larger the dipole moment, the more polar the bond. For a nonpolar

Go Figure

If the charged particles are moved closer together, does μ increase, decrease, or stay the same?



▲ **Figure 8.10 Dipole and dipole moment.** When charges of equal magnitude and opposite sign Q+ and Q− are separated by a distance *r*, a dipole is produced.

molecule, such as F_2, the dipole moment is zero because the atoms are identical and the electrons in the bond between them are shared equally.

Dipole moments are experimentally measurable and are usually reported in *debyes* (D), a unit that equals 3.34×10^{-30} coulomb-meters (C-m). For molecules, we usually measure charge in units of the electronic charge e, 1.60×10^{-19} C, and distance in angstroms. This means we need to convert units whenever we want to report a dipole moment in debyes. Suppose that two charges 1+ and 1− (in units of e) are separated by 1.00 Å. The dipole moment produced is

$$\mu = Qr = (1.60 \times 10^{-19}\,\cancel{\text{C}})(1.00\,\cancel{\mathring{\text{A}}})\left(\frac{10^{-10}\,\cancel{\text{m}}}{1\,\cancel{\mathring{\text{A}}}}\right)\left(\frac{1\text{ D}}{3.34 \times 10^{-30}\,\cancel{\text{C-m}}}\right) = 4.79\text{ D}$$

Measurement of the dipole moments can provide us with valuable information about the charge distributions in molecules, as illustrated in Sample Exercise 8.5.

Sample Exercise 8.5

Dipole Moments of Diatomic Molecules

The bond length in the HCl molecule is 1.27 Å. (**a**) Calculate the dipole moment, in debyes, that results if the charges on the H and Cl atoms were 1+ and 1− respectively. (**b**) The experimentally measured dipole moment of HCl(g) is 1.08 D. What magnitude of charge, in units of e, on the H and Cl atoms leads to this dipole moment?

SOLUTION

Analyze and Plan We are asked in part (a) to calculate the dipole moment of HCl that would result if there were a full charge transferred from H to Cl. We can use Equation 8.10 to obtain this result. In part (b), we are given the actual dipole moment for the molecule and will use that value to calculate the actual partial charges on the H and Cl atoms.

Solve

(**a**) Because Cl is more electronegative than H, we expect that the Cl atom has a negative charge and the H atom has a positive charge. The magnitude of the charge on each atom is the electronic charge, $e = 1.60 \times 10^{-19}$ C. The separation is 1.27 Å. The dipole moment is therefore:

$$\mu = Qr = (1.60 \times 10^{-19}\,\cancel{\text{C}})(1.27\,\cancel{\mathring{\text{A}}})\left(\frac{10^{-10}\,\cancel{\text{m}}}{1\,\cancel{\mathring{\text{A}}}}\right)\left(\frac{1\text{ D}}{3.34 \times 10^{-30}\,\cancel{\text{C-m}}}\right) = 6.08\text{ D}$$

(**b**) We know the value of μ, 1.08 D, and the value of r, 1.27 Å. We want to calculate the value of Q:

$$Q = \frac{\mu}{r} = \frac{(1.08\,\cancel{\text{D}})\left(\dfrac{3.34 \times 10^{-30}\text{ C-}\cancel{\text{m}}}{1\,\cancel{\text{D}}}\right)}{(1.27\,\cancel{\mathring{\text{A}}})\left(\dfrac{10^{-10}\,\cancel{\text{m}}}{1\,\cancel{\mathring{\text{A}}}}\right)} = 2.84 \times 10^{-20}\text{ C}$$

We can readily convert this charge to units of e:

$$\text{Charge in } e = (2.84 \times 10^{-20}\,\cancel{\text{C}})\left(\frac{1e}{1.60 \times 10^{-19}\,\cancel{\text{C}}}\right) = 0.178e$$

Thus, the experimental dipole moment indicates that the charge separation in the HCl molecule is:

$$\overset{0.178+}{\text{H}}\text{—}\overset{0.178-}{\text{Cl}}$$

Because the experimental dipole moment is less than that calculated in part (a), the charges on the atoms are much less than a full electronic charge. We could have anticipated this because the H—Cl bond is polar covalent rather than ionic.

Practice Exercise

The dipole moment of chlorine monofluoride, ClF(g), is 0.88 D. The bond length of the molecule is 1.63 Å. (**a**) Which atom is expected to have the partial negative charge? (**b**) What is the charge on that atom in units of e?

Table 8.2 presents the bond lengths and dipole moments of the hydrogen halides. Notice that as we proceed from HF to HI, the electronegativity difference decreases and the bond length increases. The first effect decreases the amount of charge separated and causes the dipole moment to decrease from HF to HI, even though the bond length is increasing. Calculations identical to those used in Sample Exercise 8.5 show that the charges on the atoms decrease from 0.41+ and 0.41− in HF to 0.057+ and 0.057− in HI. We can visualize the varying degree of electronic charge shift in these substances from computer-generated renderings based on calculations of electron distribution, as shown

TABLE 8.2 Bond Lengths, Electronegativity Differences, and Dipole Moments of the Hydrogen Halides

Compound	Bond Length (Å)	Electronegativity Difference	Dipole Moment (D)
HF	0.92	1.9	1.82
HCl	1.27	0.9	1.08
HBr	1.41	0.7	0.82
HI	1.61	0.4	0.44

in **Figure 8.11**. For these molecules, the change in the electronegativity difference has a greater effect on the dipole moment than does the change in bond length.

Before leaving this section, let's return to the LiF molecule in Figure 8.9. Under standard conditions, LiF exists as an ionic solid with an arrangement of atoms analogous to the sodium chloride structure shown in Figure 8.4. However, it is possible to generate LiF *molecules* by vaporizing the ionic solid at high temperature. The molecules have a dipole moment of 6.28 D and a bond distance of 1.53 Å. From these values we can calculate the charge on lithium and fluorine to be 0.857+ and 0.857−, respectively. This bond is extremely polar, and the presence of such large charges strongly favors the formation of an extended ionic lattice in which each lithium ion is surrounded by fluoride ions and vice versa. But even here, the experimentally determined charges on the ions are still not 1+ and 1−. This tells us that even in ionic compounds, there is still some covalent contribution to the bonding.

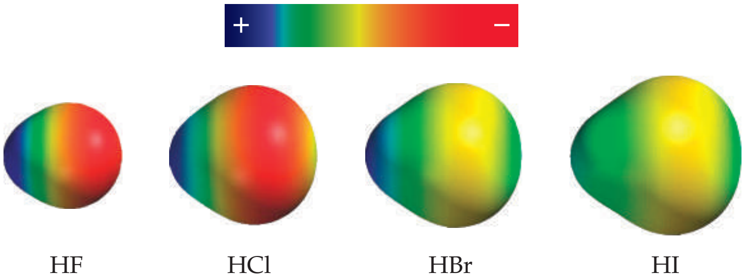
Comparing Ionic and Covalent Bonding

To understand the interactions responsible for chemical bonding, it is advantageous to treat ionic and covalent bonding separately. That is the approach taken in this chapter, as well as in most other undergraduate-level chemistry texts. In reality, however, there is a continuum between the extremes of ionic and covalent bonding. This lack of a well-defined separation between the two types of bonding may seem unsettling or confusing at first.

The simple models of ionic and covalent bonding presented here go a long way toward understanding and predicting the structures and properties of chemical compounds. When covalent bonding is dominant, we expect compounds to exist as molecules,* having all the properties we associate with molecular substances, such as relatively low melting and boiling points and nonelectrolyte behavior when dissolved in water. When ionic bonding is dominant, we expect the compounds to be brittle, high-melting solids with extended lattice structures, exhibiting strong electrolyte behavior when dissolved in water.

Go Figure

As you go from HF to HI, does the H—X bond become more or less polar?



▲ **Figure 8.11 Charge separation in the hydrogen halides.** In HF, the strongly electronegative F pulls much of the electron density away from H. In HI, the I, being much less electronegative than F, does not attract the shared electrons as strongly, so the bond is far less polar.

---

*There are some exceptions to this statement, such as network solids, including diamond, silicon, and germanium, where an extended structure is formed even though the bonding is clearly covalent. These substances are discussed in Section 12.7.

Not surprisingly, there are exceptions to these general characterizations, some of which we examine later in the book. Nonetheless, the ability to quickly categorize the predominant bonding interactions in a substance as covalent or ionic imparts considerable insight into the properties of that substance. The question then becomes what is the best way to recognize which type of bonding dominates?

The simplest approach is to assume that the interaction between a metal and a nonmetal is ionic and that the interaction between two nonmetals is covalent. While this classification scheme is reasonably predictive, there are far too many exceptions to allow us to use it blindly. For example, tin is a metal and chlorine is a nonmetal, but $SnCl_4$ is a molecular substance that exists as a colorless liquid at room temperature. It freezes at −33 °C and boils at 114 °C. The characteristics of $SnCl_4$ are not those typical of an ionic substance. Is there a more predictable way of determining what type of bonding is prevalent in a compound? A more sophisticated approach is to use the difference in electronegativity as the main criterion for determining whether ionic or covalent bonding will be dominant. This approach correctly predicts the bonding in $SnCl_4$ to be polar covalent based on an electronegativity difference of 1.2 and at the same time correctly predicts the bonding in NaCl to be predominantly ionic based on an electronegativity difference of 2.1.

Evaluating bonding based on electronegativity difference is a useful system, but it has one shortcoming. The electronegativity values given in Figure 8.8 do not take into account changes in bonding that accompany changes in the oxidation state of the metal. (Section 4.4) For example, Figure 8.8 gives the electronegativity difference between manganese and oxygen as $3.5 - 1.5 = 2.0$, which falls in the range where the bonding is normally considered ionic (the electronegativity difference for NaCl is $3.0 - 0.9 = 2.1$). Therefore, it is not surprising to learn that manganese(II) oxide, MnO, is a green solid that melts at 1842 °C and has the same crystal structure as NaCl.

However, the bonding between manganese and oxygen is not always ionic. Manganese(VII) oxide, Mn_2O_7, is a green liquid that freezes at 5.9 °C, an indication that covalent rather than ionic bonding dominates. The change in the oxidation state of manganese is responsible for the change in bonding. In general, as the oxidation state of a metal increases, so does the degree of covalent bonding. When the oxidation state of the metal is highly positive (roughly speaking, +4 or larger), we can expect significant covalency in the bonds it forms with nonmetals. Thus, metals in high oxidation states form molecular substances, such as Mn_2O_7, or polyatomic ions, such as MnO_4^- and CrO_4^{2-}, rather than ionic compounds.

Self-Assessment Exercises

SAE 8.9 Which of the following statements about electronegativity is *false*? (**a**) Electronegativity is a measure of the ability of an atom in a molecule to attract electrons to itself. (**b**) Fluorine is the most electronegative element. (**c**) Elements that have a high electronegativity generally have a high first ionization energy and a high electron affinity. (**d**) Electronegativity generally increases from top to bottom in the periodic table. (**e**) The alkali metals are the family that has the lowest electronegativity values.

SAE 8.10 Arrange the following elements in order of lowest to highest electronegativity: S, Cl, Ca, As, Rb.

(**a**) $\mathrm{Rb} < \mathrm{Ca} < \mathrm{As} < \mathrm{S} < \mathrm{Cl}$
(**b**) $\mathrm{Ca} < \mathrm{As} < \mathrm{Rb} < \mathrm{Cl} < \mathrm{S}$
(**c**) $\mathrm{S} < \mathrm{Cl} < \mathrm{Ca} < \mathrm{As} < \mathrm{Rb}$
(**d**) $\mathrm{Rb} < \mathrm{Ca} < \mathrm{Cl} < \mathrm{As} < \mathrm{S}$

SAE 8.11 Arrange the following bonds in order of increasing polarity: B—Cl, P—S, Al—F, Br—Br.

(**a**) $\text{P—S} < \text{Br—Br} < \text{Al—F} < \text{B—Cl}$
(**b**) $\text{Br—Br} < \text{P—S} < \text{Al—F} < \text{B—Cl}$
(**c**) $\text{B—Cl} < \text{Br—Br} < \text{P—S} < \text{Al—F}$
(**d**) $\text{Br—Br} < \text{P—S} < \text{B—Cl} < \text{Al—F}$

SAE 8.12 The ICl molecule has a dipole moment of 1.24 D and a bond length of 2.32 Å. In units of the electronic charge, what is the partial charge on the I atom in the ICl molecule? (**a**) 0.11+ (**b**) 0.11− (**c**) 0.26+ (**d**) 0.26− (**e**) 0

SAE 8.13 In each of the following pairs, one compound is a molecular substance and one is an ionic substance: PCl_3 and $ScCl_3$; CrF_2 and MoF_6; OsO_4 and La_2O_3. Which of the compounds are molecular substances? (**a**) PCl_3, CrF_2, OsO_4 (**b**) $ScCl_3$, CrF_2, La_2O_3 (**c**) PCl_3, MoF_6, OsO_4 (**d**) $ScCl_3$, MoF_6, La_2O_3

8.5 | Drawing Lewis Structures

Lewis structures can help us understand the bonding in many compounds and are frequently used when discussing the properties of molecules. For this reason, drawing Lewis structures is an important skill that you should practice.

We use the following procedure to draw Lewis structures for molecules. We will need to know the atoms involved and which atoms are bonded to one another.

How to Draw Lewis Structures

1. *Sum the valence electrons from all atoms, taking into account overall charge.* Use the periodic table to help you determine the number of valence electrons in each atom. For an anion, add one electron to the total for each negative charge. For a cation, subtract one electron from the total for each positive charge. Do not worry about keeping track of which electrons come from which atoms. Only the total number is important.
2. *Write the symbols for the atoms, show which atoms are attached to which, and connect them with a single bond (a line, representing* two *electrons).* Chemical formulas are often written in the order in which the atoms are connected in the molecule or ion. The formula HCN, for example, tells you that the carbon atom is bonded to the H and to the N. In many polyatomic molecules and ions, the central atom is usually written first, as in CO_3^{2-} and SF_4. Remember that the central atom is generally less electronegative than the atoms surrounding it. In other cases, you may need more information before you can draw the Lewis structure.
3. *Complete the octets around all the atoms bonded to the central atom.* Keep in mind that a hydrogen atom has only a single pair of electrons around it.
4. *Place any remaining electrons on the central atom,* even if doing so results in more than an octet of electrons around the atom.
5. *If there are not enough electrons to give the central atom an octet, try multiple bonds.* Use one or more of the unshared pairs of electrons on the atoms bonded to the central atom to form double or triple bonds.

Learning Objectives

When you finish Section 8.5, you should be able to:

- Construct Lewis structures for molecules and polyatomic ions.
- Determine the formal charge for each atom in a molecule from its Lewis structure.
- Use formal charges to determine the dominant Lewis structure for a molecule or ion.

The following examples of this procedure will help you put it into practice.

Sample Exercise 8.6

Drawing a Lewis Structure

Draw the Lewis structure for phosphorus trichloride, PCl_3.

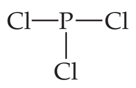
SOLUTION

Analyze and Plan We are asked to draw a Lewis structure from a molecular formula. Our plan is to follow the five-step procedure just described.

Solve First, we sum the valence electrons. Phosphorus (group 5A) has five valence electrons, and each chlorine (group 7A) has seven. The total number of valence electrons is therefore

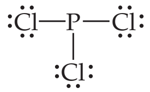
$$5 + (3 \times 7) = 26$$

Second, we arrange the atoms to show which atom is connected to which, and we draw a single bond between them. There are various ways the atoms might be arranged. It helps to know, though, that in binary compounds the first element in the chemical formula is generally surrounded by the remaining atoms. So, we proceed to draw a skeleton structure in which a single bond connects the P atom to each Cl atom:

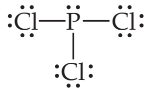


(It is not crucial that the Cl atoms be to the left of, right of, and below the P atom—any structure that shows each of the three Cl atoms bonded to P will work.)

Third, we add Lewis electron dots to complete the octets on the atoms bonded to the central atom. Completing the octets around each Cl atom accounts for 24 electrons (remember, each line in our structure represents *two* electrons):



Fourth, recalling that our total number of electrons is 26, place the remaining two electrons on the central atom, P, which completes its octet:



This structure gives each atom an octet, so we stop at this point. (In checking for octets, remember to count a single bond as two electrons.)

Practice Exercise

(**a**) How many valence electrons should appear in the Lewis structure for CH_2Cl_2?
(**b**) Draw the Lewis structure.

Sample Exercise 8.7

Lewis Structure with a Multiple Bond

Draw the Lewis structure for HCN.

SOLUTION

Hydrogen has one valence electron, carbon (group 4A) has four, and nitrogen (group 5A) has five. The total number of valence electrons is, therefore, $1 + 4 + 5 = 10$. In principle, there are different ways in which we might choose to arrange the atoms. Because hydrogen can accommodate only one electron pair, it always has only one single bond associated with it. Therefore, C—H—N is an impossible arrangement. The remaining two possibilities are H—C—N and H—N—C. The first is the arrangement found experimentally. You might have guessed this because the formula is written with the atoms in this order, and carbon is less electronegative than nitrogen. Thus, we begin with the skeleton structure

$$\mathrm{H{-}C{-}N}$$

The two bonds account for four electrons. The H atom can have only two electrons associated with it, and so we will not add any more electrons to it. If we place the remaining six electrons around N to give it an octet, we do not achieve an octet on C:

We therefore try a double bond between C and N, using one of the unshared pairs we placed on N. Again, we end up with fewer than eight electrons on C, and so we next try a triple bond. This structure gives an octet around both C and N:

The octet rule is satisfied for the C and N atoms, and the H atom has two electrons around it. This is a correct Lewis structure.

Practice Exercise

Draw the Lewis structure for (**a**) CO, (**b**) C_2H_4.

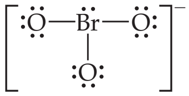
Sample Exercise 8.8

Lewis Structure for a Polyatomic Ion

Draw the Lewis structure for the BrO_3^- ion.

SOLUTION

Bromine (group 7A) has seven valence electrons, and oxygen (group 6A) has six. We must add one more electron to our sum to account for the 1− charge of the ion. The total number of valence electrons is, therefore, $7 + (3 \times 6) + 1 = 26$. For oxyanions—$SO_4^{2-}$, NO_3^-, CO_3^{2-}, and so forth—the oxygen atoms surround the central nonmetal atom. After arranging the O atoms around the Br atom, drawing single bonds, and distributing the unshared electron pairs, we have



Notice that the Lewis structure for an ion is written in brackets and the charge is shown outside the brackets at the upper right.

Practice Exercise

Draw the Lewis structure for (**a**) ClO_2^-, (**b**) PO_4^{3-}.

Formal Charge and Alternative Lewis Structures

When we draw a Lewis structure, we are describing how the electrons are distributed in a molecule or polyatomic ion. In some instances, we can draw two or more valid Lewis structures for a molecule that all obey the octet rule. All of these structures can be thought of as contributing to the *actual* arrangement of the electrons in the molecule, but not all of them will contribute to the same extent. How do we decide which one of several Lewis structures is the most important? One approach is to do some "bookkeeping" of the valence electrons to determine the *formal charge* of each atom in each Lewis structure. The **formal charge** of any atom in a molecule is the charge the atom would have if each bonding electron pair in the molecule were shared equally between its two atoms.

How to Calculate the Formal Charges of Atoms in Lewis Structures

1. *All* unshared (nonbonding) electrons are assigned to the atom on which they are found.
2. For any bond—single, double, or triple—*half* of the bonding electrons are assigned to each atom in the bond.
3. The formal charge of each atom is calculated by subtracting the number of electrons assigned to the atom from the number of valence electrons in the neutral atom:

Formal charge =

$$\text{valence electrons} - \left[\tfrac{1}{2}(\text{bonding electrons}) + \text{nonbonding electrons}\right] \qquad [8.11]$$

Let's practice by calculating the formal charges for the atoms in the cyanide ion, CN^-, which has the Lewis structure

$$[:C\equiv N:]^-$$

The neutral C atom has four valence electrons. There are six electrons in the cyanide triple bond and two nonbonding electrons on C. We calculate the formal charge on C as $4 - \left[\frac{1}{2}(6) + 2\right] = -1$. For N, the valence electron count is five; there are six electrons in the cyanide triple bond, and two nonbonding electrons on the N. The formal charge on N is $5 - \left[\frac{1}{2}(6) + 2\right] = 0$. We can draw the whole ion with its formal charges as

$$[:\overset{-1}{C}\equiv \overset{0}{N}:]^-$$

Notice that the sum of the formal charges equals the overall charge on the ion, 1−. The formal charges on a neutral molecule must add to zero, whereas those on an ion must add to give the charge on the ion.

If we can draw several Lewis structures for a molecule, the concept of formal charge can help us decide which is the most important, which we shall call the *dominant* Lewis structure. One Lewis structure for CO_2, for instance, has two double bonds. However, we can also satisfy the octet rule by drawing a Lewis structure having one single bond and one triple bond. Calculating formal charges in these structures, we have

	$\underset{\cdot\cdot}{\ddot{O}}=C=\underset{\cdot\cdot}{\ddot{O}}$			$:\underset{\cdot\cdot}{\ddot{O}}-C\equiv O:$		
Valence electrons:	6	4	6	6	4	6
−(Electrons assigned to atom):	6	4	6	7	4	5
Formal charge:	0	0	0	−1	0	+1

Note that in both cases the formal charges add up to zero, as they must because CO_2 is a neutral molecule. So, which is the dominant structure? As a general rule, when more than one Lewis structure is possible, we use the following guidelines to choose the dominant one:

How to Identify the Dominant Lewis Structure

1. The dominant Lewis structure is generally the one in which the atoms bear formal charges closest to zero.
2. A Lewis structure in which any negative charges reside on the more electronegative atoms is generally more dominant than one that has negative charges on the less electronegative atoms.

Thus, the first Lewis structure of CO_2 is the dominant one because the atoms carry no formal charges and so satisfy the first guideline. The other Lewis structure shown (and the similar one that has a triple bond to the left O and a single bond to the right O) contribute to the actual structure to a much smaller extent.

Although the concept of formal charge helps us to arrange alternative Lewis structures in order of importance, it is important to remember that *formal charges do not represent real charges on atoms*. These charges are just a bookkeeping convention. The actual charge distributions in molecules and ions are determined not by formal charges but by a number of other factors, including electronegativity differences between atoms.

Sample Exercise 8.9

Lewis Structures and Formal Charges

Three possible Lewis structures for the thiocyanate ion, NCS^-, are

$$[:\underset{\cdot\cdot}{\overset{\cdot\cdot}{N}}-C\equiv S:]^- \qquad [\underset{\cdot\cdot}{\overset{\cdot\cdot}{N}}=C=\underset{\cdot\cdot}{\overset{\cdot\cdot}{S}}]^- \qquad [:N\equiv C-\underset{\cdot\cdot}{\overset{\cdot\cdot}{S}}:]^-$$

(**a**) Determine the formal charges in each structure.

(**b**) Based on the formal charges, which Lewis structure is the dominant one?

SOLUTION

(**a**) Neutral N, C, and S atoms have five, four, and six valence electrons, respectively. We can determine the formal charges in the three structures by using the rules we just discussed:

$$[:\overset{-2}{\underset{\cdot\cdot}{\overset{\cdot\cdot}{N}}}-\overset{0}{C}\equiv \overset{+1}{S}:]^- \qquad [\overset{-1}{\underset{\cdot\cdot}{\overset{\cdot\cdot}{N}}}=\overset{0}{C}=\overset{0}{\underset{\cdot\cdot}{\overset{\cdot\cdot}{S}}}]^- \qquad [:\overset{0}{N}\equiv \overset{0}{C}-\overset{-1}{\underset{\cdot\cdot}{\overset{\cdot\cdot}{S}}}:]^-$$

As they must, the formal charges in all three structures sum to $1-$, the overall charge of the ion.

(**b**) The dominant Lewis structure generally produces formal charges of the smallest magnitude (guideline 1). That eliminates the left structure as the dominant one. Further, as discussed in Section 8.4, N is more electronegative than C or S, so we expect any negative formal charge to reside on the N atom (guideline 2). For these two reasons, the middle Lewis structure is the dominant one for NCS^-.

Practice Exercise

The cyanate ion, NCO^-, has three possible Lewis structures. (**a**) Draw these three structures and assign formal charges in each. (**b**) Which Lewis structure is dominant?

A CLOSER LOOK Oxidation Numbers, Formal Charges, and Actual Partial Charges

In Chapter 4 we introduced the rules for assigning *oxidation numbers* to atoms. The concept of electronegativity is the basis of these numbers. An atom's oxidation number is the charge the atom would have if its bonds were completely ionic. That is, in determining oxidation numbers, all shared electrons are counted with the more electronegative atom. For example, consider the Lewis structure of HCl in **Figure 8.12**(a). To assign oxidation numbers, both electrons in the covalent bond between the atoms are assigned to the more electronegative Cl atom. This procedure gives Cl eight valence electrons, one more than in the neutral atom. Thus, its oxidation number is -1. Hydrogen has no valence electrons when they are counted this way, giving it an oxidation number of $+1$.

In assigning formal charges to the atoms in HCl [Figure 8.12(b)], we ignore electronegativity; the electrons in bonds are assigned equally to the two bonded atoms. In this case Cl has seven assigned electrons, the same as that of the neutral Cl atom, and H has one assigned electron. Thus, the formal charges of both Cl and H in this compound are 0.

Neither oxidation number nor formal charge gives an accurate depiction of the actual charges on atoms because oxidation numbers overstate the role of electronegativity and formal charges ignore it. It seems reasonable that electrons in covalent bonds should be apportioned according to the relative electronegativities of the bonded atoms. Figure 8.8 shows that Cl has an electronegativity of 3.0, while the electronegativity value of H is 2.1. The more electronegative Cl atom might therefore be expected to have roughly $3.0/(3.0 + 2.1) = 0.59$ of the electrical charge in the bonding pair, whereas the H atom would have $2.1/(3.0 + 2.1) = 0.41$ of the charge. Because the bond consists of two electrons, the Cl atom's share is $0.59 \times 2e = 1.18e$, or $0.18e$ more than the neutral Cl atom. This gives rise to a partial negative charge of $0.18-$ on Cl and therefore a partial positive charge of $0.18+$ on H. (Notice again that we place the plus and minus signs *before* the magnitude in writing oxidation numbers and formal charges but *after* the magnitude in writing actual charges.)

The dipole moment of HCl gives an experimental measure of the partial charge on each atom. In Sample Exercise 8.5 we saw that the dipole moment of HCl corresponds to a partial charge of $0.178+$ on H and $0.178-$ on Cl, in remarkably good agreement with our simple approximation based on electronegativities. Although our approximation method provides ballpark numbers for the magnitude of charge on atoms, the relationship between electronegativities and charge separation is generally more complicated. As we have already seen, computer programs employing quantum-mechanical principles have been developed to obtain more accurate estimates of the partial charges on atoms, even in complex molecules. A computer-graphical representation of the calculated charge distribution in HCl is shown in Figure 8.12(c).

8.6 | Resonance Structures

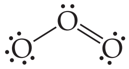
We sometimes encounter molecules and ions in which the experimentally determined arrangement of atoms is not adequately described by a single dominant Lewis structure. In such instances, we use multiple equivalent Lewis structures to describe the molecule or ion, a phenomenon we call *resonance*.

Learning Objective

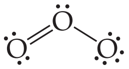
When you finish Section 8.6, you should be able to:

- Use resonance structures to describe the electron distribution in a molecule or ion that does not have a single dominant Lewis structure.

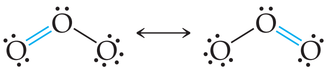
Let's consider ozone, O_3, which is a bent molecule with two equal oxygen–oxygen bond lengths (**Figure 8.13**). Because each oxygen atom contributes 6 valence electrons, the ozone molecule has 18 valence electrons. This means the Lewis structure must have one O—O single bond and one O═O double bond to attain an octet about each atom:



However, this single structure cannot by itself be dominant because it requires that one O—O bond be different from the other, contrary to the observed structure. We would expect the O═O double bond to be shorter than the O—O single bond. In drawing the Lewis structure, however, we could just as easily have put the O═O bond on the left:



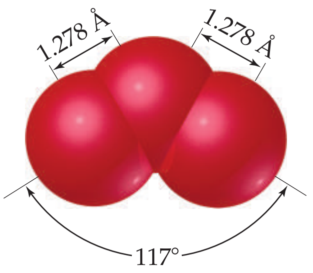
There is no reason for one of these Lewis structures to be dominant because they are equally valid representations of the molecule. The placement of the atoms in these two alternative but completely equivalent Lewis structures is the same, but the placement of the electrons is different; we call Lewis structures of this sort **resonance structures**. To describe the structure of ozone properly, we write both resonance structures and use a double-headed arrow to indicate that the real molecule is described by an average of the two:



To understand why certain molecules require more than one resonance structure, we can draw an analogy to mixing paint (**Figure 8.14**). Blue and yellow are both primary colors of paint pigment. An equal blend of blue and yellow pigments produces green pigment. We cannot describe green paint in terms of a single primary color, yet it still has its own identity. Green paint does not oscillate between its two primary colors: It is not blue

Go Figure

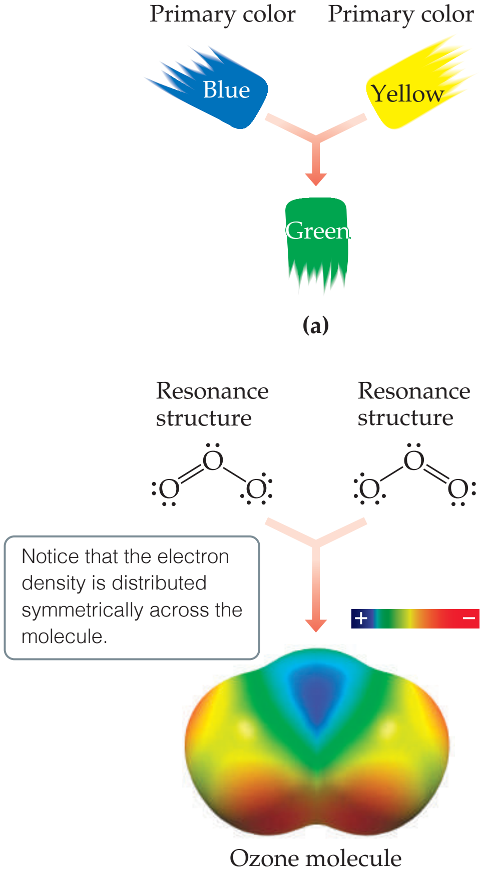
What feature of this structure suggests that the two outer O atoms are in some way equivalent to each other?



▲ **Figure 8.13** **Molecular structure of ozone.**

Go Figure

Is the electron density consistent with equal contributions from the two resonance structures for O_3? Explain.



(a)

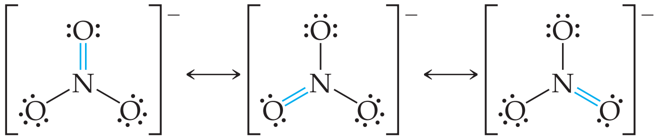
(b)

▲ **Figure 8.14 Resonance.** Describing a molecule as a blend of different resonance structures is similar to describing a paint color as a blend of primary colors. (**a**) Green paint is a blend of blue and yellow. We cannot describe green as a single primary color. (**b**) The ozone molecule is a blend of two resonance structures. We cannot describe the ozone molecule in terms of a single Lewis structure.

part of the time and yellow the rest of the time. Similarly, molecules such as ozone cannot be described as oscillating between the two individual Lewis structures shown previously—there are two equivalent dominant Lewis structures that contribute equally to the actual structure of the molecule.

The actual arrangement of the electrons in molecules such as O_3 must be considered as a blend of two (or more) Lewis structures. By analogy to the green paint, the molecule has its own identity separate from the individual resonance structures. For example, the ozone molecule always has two equivalent O—O bonds whose lengths are intermediate between the lengths of an oxygen–oxygen single bond and an oxygen–oxygen double bond. Another way of looking at it is to say that the rules for drawing Lewis structures do not allow us to have a single dominant structure for the ozone molecule. For example, there are no rules for drawing half-bonds. We can get around this limitation by drawing two equivalent Lewis structures that, when averaged, amount to something very much like what is observed experimentally.

As an additional example of resonance structures, consider the nitrate ion, NO_3^-, for which three equivalent Lewis structures can be drawn:

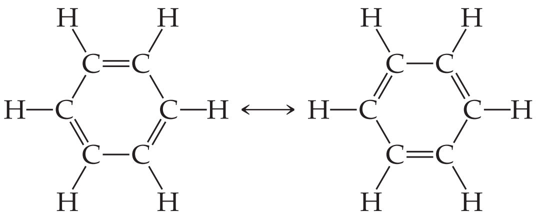


Notice that the arrangement of atoms is the same in each structure; only the placement of electrons differs. In writing resonance structures, the same atoms must be bonded to each other in all structures, so that the only differences are in the arrangements of electrons. All three NO_3^- Lewis structures are equally dominant and taken together adequately describe the ion, in which all three N=O bond lengths are the same.

For some molecules or ions, all possible Lewis structures may not be equivalent; in other words, one or more resonance structures are more dominant than others. We will encounter examples of this as we proceed.

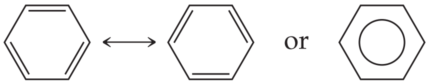
Resonance in Benzene

Resonance is an important concept in describing the bonding in organic molecules, particularly *aromatic* organic molecules, a category that includes the hydrocarbon *benzene,* C_6H_6. The six C atoms are bonded in a hexagonal ring, and one H atom is bonded to each C atom. We can write two equivalent dominant Lewis structures for benzene, each of which satisfies the octet rule. These two structures are in resonance:



Note that the double bonds are in different places in the two structures. Each of these resonance structures shows three carbon–carbon single bonds and three carbon–carbon double bonds. However, experimental data show that all six C—C bonds are of equal length, 1.40 Å, intermediate between the typical bond lengths for a C—C single bond (1.54 Å) and a C=C double bond (1.34 Å). Each of the C—C bonds in benzene can be thought of as a blend of a single bond and a double bond (**Figure 8.15**).

Benzene is commonly represented by omitting the hydrogen atoms and showing only the carbon–carbon framework with the vertices unlabeled. In this convention, the resonance in the molecule is represented either by two structures separated by a double-headed arrow or by a shorthand notation in which we draw a hexagon with a circle inside:

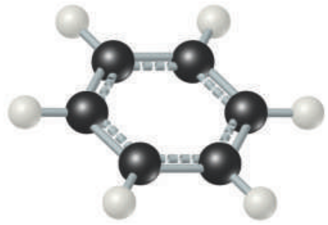


The shorthand notation reminds us that benzene is a blend of two resonance structures—it emphasizes that the C═C double bonds cannot be assigned to specific edges of the hexagon. Chemists use both representations of benzene interchangeably.

The bonding arrangement in benzene confers special stability to the molecule. As a result, millions of organic compounds contain the six-membered ring characteristic of benzene. Many of these compounds are important in biochemistry, in pharmaceuticals, and in the production of modern materials.

Go Figure

What is the significance of the dashed bonds in this ball-and-stick model?



▲ **Figure 8.15 Benzene, an "aromatic" organic compound.** The benzene molecule is a regular hexagon of carbon atoms with a hydrogen atom bonded to each one. The dashed lines represent the blending of two equivalent resonance structures, leading to C—C bonds that are intermediate between single and double bonds.

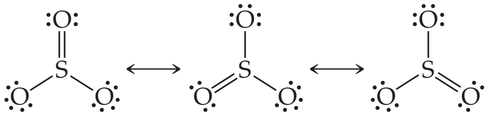
Sample Exercise 8.10

Resonance Structures

Which is predicted to have the shorter sulfur–oxygen bonds, SO_3 or SO_3^{2-}?

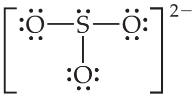
SOLUTION

The sulfur atom has six valence electrons, as does oxygen. Thus, SO_3 contains 24 valence electrons. In writing the Lewis structure, we see that three equivalent resonance structures can be drawn:



As with NO_3^- the actual structure of SO_3 is an equal blend of all three. Thus, each S—O bond length should be about one-third of the way between the length of a single bond and the length of a double bond. That is, S—O should be shorter than single bonds but not as short as double bonds.

The SO_3^{2-} ion has 26 electrons, which leads to a dominant Lewis structure in which all the S—O bonds are single:



Our analysis of the Lewis structures thus far leads us to conclude that SO_3 should have the shorter S—O bonds and SO_3^{2-} the longer ones. This conclusion is correct: The experimentally measured S—O bond lengths are 1.42 Å in SO_3 and 1.51 Å in SO_3^{2-}

▶ **Practice Exercise**

Draw two equivalent resonance structures for the formate ion, HCO_2^-.

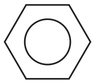
Self-Assessment Exercises

SAE 8.17 The SO_2 molecule, which has a central S atom bonded to two O atoms, has ________ equivalent resonance structures, and the two S—O bonds are ________. **(a)** one, the same length **(b)** two, the same length **(c)** one, different lengths **(d)** two, different lengths

SAE 8.18 Based on their Lewis structures, predict the ordering of the O—O bond lengths from shortest to longest in O_2, O_2^{2-} (the peroxide ion) and O_3 (ozone).

(a) $O_3 < O_2 < O_2^{2-}$
(b) $O_3 < O_2^{2-} < O_2$
(c) $O_2 < O_3 < O_2^{2-}$
(d) $O_2^{2-} < O_2 < O_3$
(e) $O_2^{2-} < O_3 < O_2$

SAE 8.19 The structure of benzene, C_6H_6, is often denoted as shown in the following figure. Which of the follow statements is *false*? **(a)** This notation is used because there are no Lewis structures for benzene that satisfy the octet rule. **(b)** This notation represents a blend of two equivalent resonance structures. **(c)** The circle indicates that there are three double bonds in each individual resonance structure for the molecule. **(d)** Each vertex of the hexagon represents a carbon atom, and the hydrogen atoms have been omitted.



8.7 | Exceptions to the Octet Rule

Learning Objectives

When you finish Section 8.7, you should be able to:

- Determine the Lewis structures of molecules or ions that have an odd number of electrons or less than an octet of electrons around an atom.
- Determine the Lewis structures of molecules or ions with more than an octet of electrons around an atom.

The octet rule is so simple and useful in introducing the basic concepts of bonding that you might assume it is always obeyed. In Section 8.2, however, we noted its limitation in dealing with ionic compounds of the transition metals. The rule also fails in many situations involving covalent bonding. In this section, we examine molecules that do not conform to the octet rule.

Three main categories of molecules and ions are exceptions to the octet rule:

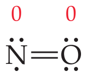
1. Molecules and polyatomic ions containing an odd number of electrons
2. Molecules and polyatomic ions in which an atom has fewer than an octet of valence electrons
3. Molecules and polyatomic ions in which an atom has more than an octet of valence electrons

Odd Number of Electrons

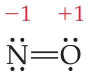
In the vast majority of molecules and polyatomic ions, the total number of valence electrons is even, and complete pairing of electrons occurs. However, in some relatively common molecules and polyatomic ions, such as ClO_2, NO, NO_2, and O_2^-, the number of valence electrons is odd. Because the number of electrons is odd, complete pairing of these electrons is impossible, so an octet around each atom cannot be achieved. For example, NO contains $5 + 6 = 11$ valence electrons. The two most important Lewis structures for this molecule are

and

In any molecule or ion with an odd number of electrons, the Lewis structure will have one unpaired electron somewhere in the structure, as we see for the NO molecule. We can still use the same tools we have already developed to determine the dominant Lewis structure. In the case of NO, we expect the structure on the left, with the unpaired electron on the N atom, to be dominant due to more favorable formal charges:

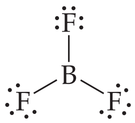


and

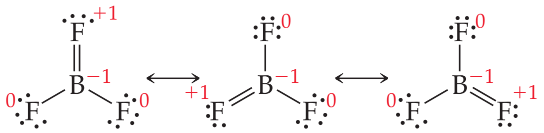


Less Than an Octet of Valence Electrons

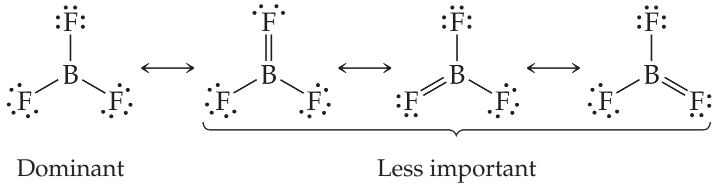
A second type of exception occurs when there are fewer than eight valence electrons around an atom in a molecule or polyatomic ion. This situation is relatively rare (with the exception of hydrogen and helium as we have already discussed), and is most often encountered in compounds of boron and beryllium. For example, if we apply the first steps of our procedure for drawing Lewis structures to boron trifluoride, BF_3, we obtain the structure



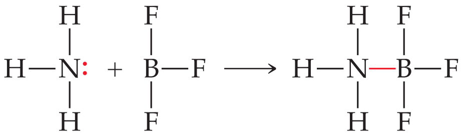
which has only six electrons around the boron atom. The formal charge is zero on both B and F, and we could complete the octet around boron by forming a double bond (recall that if there are not enough electrons to give the central atom an octet, a multiple bond may be the answer). In so doing, we see that there are three equivalent resonance structures (the formal charges are shown in red):



Each of these structures forces a fluorine atom to share additional electrons with the boron atom, which is inconsistent with the high electronegativity of fluorine. In fact, the formal charges indicate that this is an unfavorable situation. In each structure, the F atom involved in the B═F double bond has a formal charge of +1, while the less electronegative B atom has a formal charge of −1. Thus, the resonance structures containing a B═F double bond are less important than the one in which there are fewer than an octet of valence electrons around boron:



We usually represent BF_3 solely by the dominant resonance structure, in which there are only six valence electrons around boron. The chemical behavior of BF_3 is consistent with this representation. In particular, BF_3 reacts energetically with molecules having an unshared pair of electrons that can be used to form a bond with boron, as, for example, in the reaction

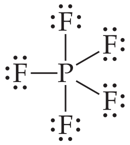


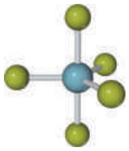
$$\mathrm{H{-}\overset{\displaystyle H}{\underset{\displaystyle H}{N}}{:}} + \mathrm{\overset{\displaystyle F}{\underset{\displaystyle F}{B}}{-}F} \longrightarrow \mathrm{H{-}\overset{\displaystyle H}{\underset{\displaystyle H}{N}}{-}\overset{\displaystyle F}{\underset{\displaystyle F}{B}}{-}F}$$

In the stable compound NH_3BF_3, boron has an octet of valence electrons. This type of behavior can be characterized as a somewhat different type of acid–base reaction—one that we discuss in Section 16.1.

More Than an Octet of Valence Electrons

The third and largest class of exceptions consists of molecules or polyatomic ions in which there are more than eight electrons in the valence shell of an atom. When we draw the Lewis structure for PF_5, for example, we are forced to place 10 electrons around the central phosphorus atom:





Molecules and ions with more than an octet of electrons around the central atom are often called *hypervalent*. Other examples of hypervalent species are SF_4, AsF_6^-, and ICl_4^-. The corresponding molecules with a second-period atom as the central atom, such as NCl_5 and OF_4, do *not* exist.

Hypervalent molecules are formed only for central atoms from period 3 and below in the periodic table. The principal reason for their formation is the relatively larger size of the central atom. For example, a P atom is large enough that five F (or even five Cl) atoms can be bonded to it without being too crowded. By contrast, a N atom is too small to accommodate five atoms bonded to it. Because size is a factor, hypervalent molecules occur most often when the central atom is bonded to the smallest and most electronegative atoms—F, Cl, and O.

The notion that a valence shell can contain more than eight electrons is also consistent with the presence of unfilled *nd* orbitals in atoms from period 3 and below. (Section 6.8) By comparison, in elements of the second period, only the 2*s* and 2*p* valence orbitals are available for bonding. However, theoretical work on the bonding in molecules such as PF_5 and SF_6 suggests that the presence of unfilled 3*d* orbitals in P and S has a relatively minor impact on the formation of hypervalent molecules. Most chemists now believe that the larger size of the atoms from periods 3 through 6 is more important to explain hypervalency than is the presence of unfilled *d* orbitals.

Sample Exercise 8.11

Lewis Structure for an Ion with More Than an Octet of Electrons

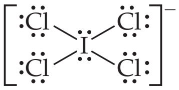
Draw the Lewis structure for ICl_4^-.

SOLUTION

Iodine (group 7A) has seven valence electrons. Each chlorine atom (group 7A) also has seven. An extra electron is added to account for the 1− charge of the ion. Therefore, the total number of valence electrons is $7 + (4 \times 7) + 1 = 36$.

The I atom is the central atom in the ion. Putting eight electrons around each Cl atom (including a pair of electrons between I and each Cl to represent the single bond between these atoms) requires $8 \times 4 = 32$ electrons.

We are thus left with $36 - 32 = 4$ electrons to be placed on the larger iodine:

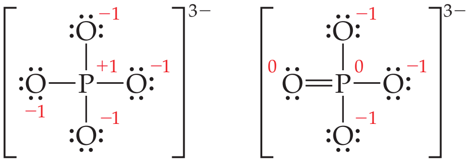


Iodine has 12 valence electrons around it, four more than needed for an octet.

Practice Exercise

(**a**) Which of the following atoms is never found with more than an octet of valence electrons around it? S, C, P, Br, I. (**b**) Draw the Lewis structure for XeF_2.

Finally, there are Lewis structures where you might have to choose between satisfying the octet rule and obtaining the most favorable formal charges by using more than an octet of electrons. For example, consider these Lewis structures for the phosphate ion, PO_4^{3-}:



The formal charges on the atoms are shown in red. In the left structure, the P atom obeys the octet rule. In the right structure, however, the P atom has five electron pairs, leading to smaller formal charges on the atoms. (You should be able to visualize that there are three additional resonance structures for the Lewis structure on the right.)

Chemists are still debating which of these two structures is dominant for PO_4^{3-}. Theoretical calculations based on quantum mechanics suggest to some researchers that the left structure is the dominant one. Other researchers claim that the bond lengths in the ion are more consistent with the right structure being dominant. This disagreement is a convenient reminder that, in general, multiple Lewis structures can contribute to the actual electron distribution in an atom or molecule.

Self-Assessment Exercises

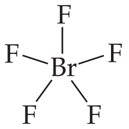
SAE 8.20 For how many of the following molecules and ions is it *not* possible to write a Lewis structure that satisfies the octet rule: NH_4^+, NO, NO_2, N_2O? (**a**) 0 (**b**) 1 (**c**) 2 (**d**) 3 (**e**) 4

SAE 8.21 How many of the following molecules are hypervalent: PF_3, PF_5, XeF_2, XeF_4? (**a**) 0 (**b**) 1 (**c**) 2 (**d**) 3 (**e**) 4

SAE 8.22 The BrF_5 molecule has a central Br atom with the five F atoms bonded to the Br, as shown in the figure. When a Lewis structure is written for BrF_5 with five Br—F single bonds, which of the following statements is or are *true*?

(**i**) There are no nonbonding electron pairs on the Br atom.
(**ii**) The Br atom is hypervalent.
(**iii**) The formal charge on the Br atom is 0.

(**a**) Only one of the statements is true. (**b**) i and ii are true. (**c**) i and iii are true. (**d**) ii and iii are true. (**e**) All three statements are.



8.8 | Strengths and Lengths of Single and Multiple Bonds

Given how small atoms and molecules are, you may be wondering how chemists explore the effectiveness of covalent chemical bonds in holding atoms together. In this final section of Chapter 8, we explore two of the common ways that chemical bonds can be examined experimentally—namely, by looking at how strong they are and how long they are. In particular, we explore the relationship between the number of bonds between a pair of atoms and the strength and length of the bond.

Learning Objective

When you finish Section 8.8, you should be able to:

- Correlate the strengths and lengths of covalent bonds with the number of bonds between an atom pair.

The stability of a molecule is related to the strengths of its covalent bonds. We saw in Chapter 5 that we can measure the average bond enthalpy of many single bonds (Table 5.4). The information in Table 5.4 is repeated in **Table 8.3**, which also includes average bond enthalpies for multiple bonds. As you might expect, the data in Table 8.3 show that multiple bonds are generally stronger than single bonds.

TABLE 8.3 Average Bond Enthalpies (kJ/mol)

Single Bonds							
C—H	413	N—H	391	O—H	463	F—F	155
C—C	348	N—N	163	O—O	146		
C—N	293	N—O	201	O—F	190	Cl—F	253

Si—C	301						
Si—O	368						
Si—Cl	464						
Multiple Bonds							
C=C	614	N=N	418	O=O	495		
C≡C	839	N≡N	941				
C=N	615	N=O	607	S=O	523		
C≡N	891			S=S	418		
C=O	799						
C≡O	1072						

Just as we can define an average bond enthalpy, we can also define an average bond length for a number of common single and multiple bonds (**Table 8.4**). For bonds between the same atoms, notice that the bonds get shorter as the number of bonds between the atoms increases. Of particular interest is the relationship, in any atom pair, among bond enthalpy, bond length, and number of bonds between the atoms. For example, we can use data in Tables 8.3 and 8.4 to compare the bond lengths and bond enthalpies of carbon–carbon single, double, and triple bonds:

C—C	C=C	C≡C
1.54 Å	1.34 Å	1.20 Å
348 kJ/mol	614 kJ/mol	839 kJ/mol

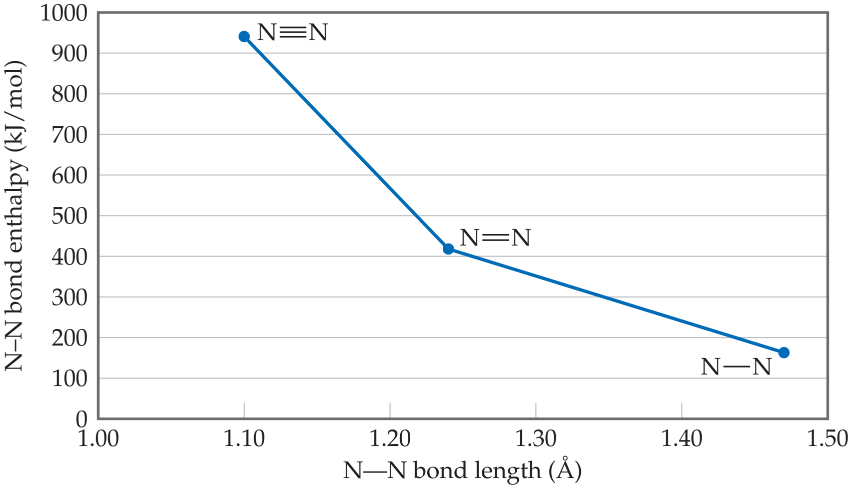
As the number of bonds between the carbon atoms increases, the bond length decreases and the average bond enthalpy increases. That is, the carbon atoms are held more closely and more tightly together. In general, *as the number of bonds between two atoms increases, the bond grows shorter and stronger*. This trend is illustrated in **Figure 8.16** for N—N single, double, and triple bonds.

TABLE 8.4 Average Bond Lengths for Some Single, Double, and Triple Bonds

Bond	Bond Length (Å)	Bond	Bond Length (Å)
C—C	1.54	N—N	1.47
C═C	1.34	N═N	1.24
C≡C	1.20	N≡N	1.10
C—N	1.43	N—O	1.36
C═N	1.38	N═O	1.22
C≡N	1.16		
		O—O	1.48
C—O	1.43	O═O	1.21
C═O	1.23		
C═O	1.13		

Go Figure

Predict the N—N bond enthalpy for an N—N bond that has resonance forms that include equal contributions from single and double N—N bonds.



▲ **Figure 8.16** **Bond strength versus bond length for N—N bonds.**

You should make one final observation from the data in Table 8.3: The average bond enthalpy of a double bond between two atoms is not exactly two times the bond enthalpy for a single bond between the same atoms. Likewise, the bond enthalpy of triple bonds is not exactly three times that for single bonds. Notice that the average bond enthalpy of a C═C double bond (614 kJ/mol) is *less* than twice that of a C—C single bond (348 kJ/mol). By comparison, the bond enthalpy for a N═N double bond (418 kJ/mol) is *more* than twice that for a N—N single bond (163 kJ/mol). As we discuss in Chapter 9, a number of factors affect the types of bonds we make between atoms. The important take-away from the data here is that not all bonds between a pair of atoms have the same strength.

Self-Assessment Exercises

SAE 8.23 Which of the following statements about the correlation of bond order with bond strength is *false*? (**a**) A double bond between two atoms is stronger than a single bond between the same two atoms. (**b**) A triple bond between two atoms is stronger than a double bond between the same two atoms. (**c**) All triple bonds have the same average bond enthalpy regardless of which atoms are bonded to one another. (**d**) The reaction enthalpy can be estimated by determining how much energy needs to be added to break bonds and how much energy is released in forming new bonds.

SAE 8.24 The average lengths for C—O, C═O, and C≡O bonds are 1.43, 1.23, and 1.13 Å, respectively. The carbonate ion, CO_3^{2-}, has a central carbon atom and three O atoms bonded to the C. All three C—O bond lengths in the carbonate ion are equal in length. Based on the Lewis structure of CO_3^{2-}, what is the most likely value for the C—O bond length in CO_3^{2-}? (**a**) less than 1.13 Å (**b**) between 1.13 and 1.23 Å (**c**) between 1.23 and 1.43 Å (**d**) greater than 1.43 Å

Putting Concepts Together

Phosgene, a substance used in poisonous gas warfare during World War I, is so named because it was first prepared by the action of sunlight on a mixture of carbon monoxide and chlorine gases. Its name comes from the Greek words *phos* (light) and *genes* (born of). Phosgene has the following elemental composition: 12.14% C, 16.17% O, and 71.69% Cl by mass. Its molar mass is 98.9 g/mol. (**a**) Determine the molecular formula of this compound. (**b**) Draw three Lewis structures for the molecule that satisfy the octet rule for each atom. (The Cl and O atoms bond to C.) (**c**) Using formal charges, determine which Lewis structure is the dominant one. (**d**) Using average bond enthalpies, estimate ΔH for the formation of gaseous phosgene from $CO(g)$ and $Cl_2(g)$.

SOLUTION

(**a**) The empirical formula of phosgene can be determined from its elemental composition. (Section 3.5) Assuming 100 g of the compound and calculating the number of moles of C, O, and Cl in this sample, we have:

$$(12.14\ \cancel{\text{g C}})\left(\frac{1\ \text{mol C}}{12.01\ \cancel{\text{g C}}}\right) = 1.011\ \text{mol C}$$

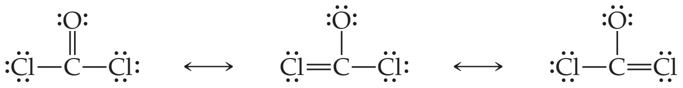
$$(16.17\ \cancel{\text{g O}})\left(\frac{1\ \text{mol O}}{16.00\ \cancel{\text{g O}}}\right) = 1.011\ \text{mol O}$$

$$(71.69\ \cancel{\text{g Cl}})\left(\frac{1\ \text{mol Cl}}{35.45\ \cancel{\text{g Cl}}}\right) = 2.022\ \text{mol Cl}$$

The ratio of the number of moles of each element, obtained by dividing each number of moles by the smallest quantity, indicates that there is one C and one O for each two Cl in the empirical formula, $COCl_2$.

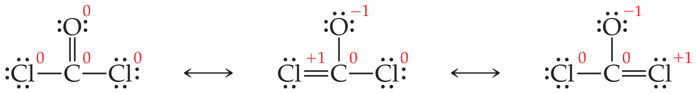
The molar mass of the empirical formula is $12.01 + 16.00 + 2(35.45) = 98.91$ g/mol, the same as the molar mass of the molecule. Thus, $COCl_2$ is the molecular formula.

(**b**) Carbon has four valence electrons, oxygen has six, and chlorine has seven, giving $4 + 6 + 2(7) = 24$ electrons for the Lewis structures. Drawing a Lewis structure with all single bonds does not give the central carbon atom an octet. Using multiple bonds, we find that three structures satisfy the octet rule:



$$\text{Cl}-\overset{\overset{\text{O}}{\|}}{\text{C}}-\text{Cl} \longleftrightarrow \text{Cl}=\overset{\overset{\text{O}}{|}}{\text{C}}-\text{Cl} \longleftrightarrow \text{Cl}-\overset{\overset{\text{O}}{|}}{\text{C}}=\text{Cl}$$

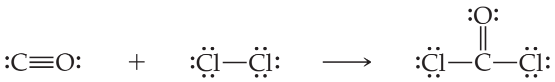
(**c**) Calculating the formal charges on each atom gives:



$$\text{Cl}^{0}-\overset{\overset{\text{O}^{0}}{\|}}{\text{C}^{0}}-\text{Cl}^{0} \longleftrightarrow \text{Cl}^{+1}=\overset{\overset{\text{O}^{-1}}{|}}{\text{C}^{0}}-\text{Cl}^{0} \longleftrightarrow \text{Cl}^{0}-\overset{\overset{\text{O}^{-1}}{|}}{\text{C}^{0}}=\text{Cl}^{+1}$$

The first structure is expected to be the dominant one because it has the lowest formal charges on each atom. Indeed, the molecule is usually represented by this single Lewis structure.

(**d**) Writing the chemical equation in terms of the Lewis structures of the molecules, we have:



$$\text{C}\equiv\text{O} + \text{Cl}-\text{Cl} \longrightarrow \text{Cl}-\overset{\overset{\text{O}}{\|}}{\text{C}}-\text{Cl}$$

Thus, the reaction involves breaking a C≡O bond and a Cl—Cl bond and forming a C═O bond and two C—Cl bonds. Using bond enthalpies from Table 8.3, we have:

$$\begin{aligned}\Delta H &= [D(\text{C}\equiv\text{O}) + D(\text{Cl}-\text{Cl})] - [D(\text{C}=\text{O}) + 2D(\text{C}-\text{Cl})]\\ &= [1072\ \text{kJ} + 242\ \text{kJ}] - [799\ \text{kJ} + 2(328\ \text{kJ})] = -141\ \text{kJ}\end{aligned}$$

The reaction is exothermic, but energy is still needed from sunlight or another source for the reaction to begin, as is the case for the combustion of $H_2(g)$ and $O_2(g)$ to form $H_2O(g)$ (see Figure 5.14).

Chapter Summary and Key Terms

CHEMICAL BONDS, LEWIS SYMBOLS, AND THE OCTET RULE (INTRODUCTION AND SECTION 8.1) In this chapter, we have focused on the interactions that lead to the formation of **chemical bonds**. We classify these bonds into three broad groups: **ionic bonds**, which result from the electrostatic forces that exist between ions of opposite charge; **covalent bonds**, which result from the sharing of electrons by two atoms; and **metallic bonds**, which result from a delocalized sharing of electrons in metals. The formation of bonds involves interactions of the outermost electrons of atoms, their valence electrons. The valence electrons of an atom can be represented by electron-dot symbols, called **Lewis symbols**. The tendencies of atoms to gain, lose, or share their valence electrons often follow the **octet rule**, which says that the atoms in molecules or ions (usually) have eight valence electrons.

IONIC BONDING (SECTION 8.2) Ionic bonding results from the transfer of electrons from one atom to another, leading to the formation of a three-dimensional lattice of charged particles. The stabilities of ionic substances result from the strong electrostatic attractions between an ion and the surrounding ions of opposite charge. The magnitude of these interactions is measured by the **lattice energy**, which is the energy needed to separate an ionic lattice into gaseous ions. Lattice energy increases with increasing charge on the ions and with decreasing distance between the ions. The **Born–Haber cycle** is a useful thermochemical cycle in which we use Hess's law to calculate the lattice energy as the sum of several steps in the formation of an ionic compound.

COVALENT BONDING (SECTION 8.3) A covalent bond results from the sharing of valence electrons between atoms. We can represent the electron distribution in molecules by means of **Lewis structures**, which indicate how many valence electrons are involved in forming bonds and how many remain as **nonbonding electron pairs** (or **lone pairs**). The octet rule helps determine how many bonds will be formed between two atoms. The sharing of one pair of electrons produces a **single bond**; the sharing of two or three pairs of electrons between two atoms produces **double** or **triple bonds**, respectively. Double and triple bonds are examples of multiple bonding between atoms. The bond length decreases as the number of bonds between the atoms increases.

BOND POLARITY AND ELECTRONEGATIVITY (SECTION 8.4) In covalent bonds, the electrons may not necessarily be shared equally between two atoms. **Bond polarity** helps describe unequal sharing of electrons in a bond. In a **nonpolar covalent bond**, the electrons in the bond are shared equally by the two atoms; in a **polar covalent bond**, one of the atoms exerts a greater attraction for the electrons than the other.

Electronegativity is a numerical measure of an atom's ability to compete with other atoms for the electrons shared between them. Fluorine is the most electronegative element, meaning it has the greatest ability to attract electrons from other atoms. Electronegativity values range from 0.7 for Cs to 4.0 for F. Electronegativity generally increases from left to right in a row of the periodic table and decreases going down a column. The difference in the electronegativities of bonded atoms can be used to determine the polarity of a bond. The greater the electronegativity difference, the more polar the bond.

A **polar molecule** is one whose centers of positive and negative charge do not coincide. Thus, a polar molecule has a positive side and a negative side. This separation of charge produces a **dipole**, the magnitude of which is given by the **dipole moment**, which is measured in debyes (D). Dipole moments increase with increasing amount of charge separated and increasing distance of separation. Any diatomic molecule X—Y in which X and Y have different electronegativities is a polar molecule.

Most bonding interactions lie between the extremes of covalent and ionic bonding. While it is generally true that the bonding between a metal and a nonmetal is predominantly ionic, exceptions to this guideline are not uncommon when the difference in electronegativity of the atoms is relatively small or when the oxidation state of the metal becomes large.

DRAWING LEWIS STRUCTURES AND RESONANCE STRUCTURES (SECTIONS 8.5 AND 8.6) If we know which atoms are connected to one another, we can draw Lewis structures for molecules and ions using a five-step procedure. Once we do so, we can determine the **formal charge** of each atom in a Lewis structure, which is the charge that the atom would have if all atoms had the same electronegativity. In general, the dominant Lewis structure will have low formal charges, with any negative formal charges residing on more electronegative atoms.

Sometimes a single dominant Lewis structure is inadequate to represent a particular molecule (or ion). In such situations, we describe the molecule by using two or more **resonance structures** for the molecule. The molecule is envisioned as a blend of these multiple resonance structures. Resonance structures are important in describing the bonding in molecules such as ozone, O_3, and the organic molecule benzene, C_6H_6.

EXCEPTIONS TO THE OCTET RULE (SECTION 8.7) The octet rule is not obeyed in all cases. Exceptions occur when (**a**) a molecule has an odd number of electrons, (**b**) it is not possible to complete an octet around an atom without forcing an unfavorable distribution of electrons, or (**c**) a large atom is surrounded by a sufficiently large number of small electronegative atoms that it has more than an octet of electrons around it. Lewis structures with more than an octet of electrons are observed for atoms in the third row and beyond in the periodic table.

STRENGTHS AND LENGTHS OF SINGLE AND MULTIPLE BONDS (SECTION 8.8) The average strengths and lengths of many common covalent bonds can be measured. Average bond enthalpies for multiple bonds are generally larger than those of single bonds. The average bond length between two atoms decreases as the number of bonds between the atoms increases, consistent with the bond being stronger as the number of bonds increases.

Key Equations

- $E_{el} = \dfrac{\kappa Q_1 Q_2}{d}$ [8.4] The potential energy of two interacting charges
- $\mu = Qr$ [8.10] The dipole moment of two charges of equal magnitude but opposite sign, separated by a distance r
- Formal charge = valence electrons $-\left[\frac{1}{2}(\text{bonding electrons}) + \text{nonbonding electrons}\right]$ [8.11] The definition of formal charge

Exam Prep

EP 8.1 If the Lewis symbol of a certain element has one dot on each of the four sides of the symbol for the element, which of the following elements could it be? (**a**) P (**b**) S (**c**) Si (**d**) B (**e**) N

EP 8.2 Which of the following statements about ionic bonding is *incorrect*? (**a**) Ionic bonds form because of the electrostatic attraction between cations and anions. (**b**) Ionic bonds are formed from the elements via the transfer of one or more electrons from one atom to another. (**c**) Energy is required to break an ionic compound into gaseous ions. (**d**) The attraction between cations and anions increases as the charges on the ions increase. (**e**) The attraction between cations and anions increases as the radii of the ions increase.

EP 8.3 Which of the following orderings of lattice energy is correct for the ionic compounds CsI, MgO, NaCl, and ScN?
(**a**) NaCl > MgO > CsI > ScN
(**b**) ScN > MgO > NaCl > CsI
(**c**) NaCl > CsI > ScN > MgO
(**d**) MgO > NaCl > ScN > CsI,
(**e**) ScN > CsI > NaCl > MgO

EP 8.4 Which of these elements is most likely to form ions with a 2+ charge? (**a**) Li (**b**) Ca (**c**) O (**d**) P (**e**) Cl

EP 8.5 Which of the following statements about the bonding of two Cl atoms to form Cl_2 is *incorrect*? (**a**) Cl_2 has a single bond. (**b**) The electrons in the Cl—Cl bond are simultaneously attracted to both Cl nuclei. (**c**) In forming the Cl—Cl bond, an electron is completely transferred from one Cl atom to the other. (**d**) Each of the Cl atoms in Cl_2 has three nonbonding pairs of electrons around it. (**e**) Both Cl atoms in Cl_2 satisfy the octet rule.

EP 8.6 Which of these molecules has the same number of shared electron pairs as unshared electron pairs? (**a**) HCl (**b**) H_2S (**c**) PF_3 (**d**) CCl_2F_2 (**e**) Br_2

EP 8.7 Consider a Lewis structure for the P_2 molecule that satisfies the octet rule. Which of the following statements is or are *true*?

(**i**) Each of the P atoms has one nonbonding electron pair.
(**ii**) The molecule has a P—P triple bond.
(**iii**) Six electrons are shared between the two P atoms.

(**a**) Only one of the statements is true. (**b**) i and ii are true. (**c**) i and iii are true. (**d**) ii and iii are true. (**e**) All three statements are true.

EP 8.8 Which of the following is the best explanation of why fluorine is the most electronegative element? (**a**) A fluorine atom easily transfers an electron to other atoms in forming ionic compounds. (**b**) Fluorine has a large first ionization energy and a large electron affinity. (**c**) The ionic radius of fluorine is larger than its bonding atomic radius. (**d**) The F_2 molecule is nonpolar. (**e**) The F^{2-} ion does not exist.

EP 8.9 Which of the following bonds is the most polar? (**a**) H—F (**b**) H—I (**c**) Se—F (**d**) N—P (**e**) Ga—Cl

EP 8.10 What would be the dipole moment for HF (bond length 0.917 Å) if it is assumed that the bond is completely ionic? (**a**) 0.917 D (**b**) 1.91 D (**c**) 2.75 D (**d**) 4.39 D (**e**) 7.37 D

EP 8.11 Tungsten dioxide, WO_2, is a solid with a melting point of about 1700 °C, whereas tungsten hexafluoride, WF_6, is a colorless gas at room temperature. Which of the following is the best explanation for these observations? (**a**) Covalent bonding dominates in WO_2 whereas ionic bonding dominates in WF_6. (**b**) O_2 has a double bond whereas F_2 has a single bond. (**c**) Fluorine does not readily form ionic compounds. (**d**) W is in a higher oxidation state in WF_6, which increases the degree of covalent bonding. (**e**) The difference in electronegativity between W and O is greater than that between W and F.

EP 8.12 Which of these molecules has a Lewis structure with a central atom having no nonbonding electron pairs? (**a**) CO_2 (**b**) H_2S (**c**) PF_3 (**d**) SiF_4 (**e**) more than one of a, b, c, d

EP 8.13 Draw the Lewis structure(s) for the molecule with the chemical formula C_2H_3N, where the N is connected to only one other atom. How many double bonds are there in the correct Lewis structure? (**a**) 0 (**b**) 1 (**c**) 2 (**d**) 3 (**e**) 4

EP 8.14 How many nonbonding electron pairs are there in the Lewis structure of the peroxide ion, O_2^{2-}? (**a**) 7 (**b**) 6 (**c**) 5 (**d**) 4 (**e**) 3

EP 8.15 The sulfate ion, SO_4^{2-}, can be drawn in many ways. If you minimize formal charge on the sulfur, how many S═O double bonds should you draw in the Lewis structure? (**a**) 0 (**b**) 1 (**c**) 2 (**d**) 3 (**e**) 4

EP 8.16 Which of these statements about resonance is *true*? (**a**) When you draw resonance structures, it is permissible to alter the way atoms are connected. (**b**) Because of multiple resonance structures, the six carbon–carbon bonds in benzene, C_6H_6, all have the same length. (**c**) "Resonance" refers to the idea that molecules are resonating rapidly between different bonding patterns. (**d**) The ethylene molecule, C_2H_4, has multiple resonance structures. (**e**) All of the above are true.

EP 8.17 Consider the following ions: NO_2^-, CO_3^{2-}, and SO_4^{2-}. For each of these, you should use a Lewis structure that satisfies the octet rule. Which of these ions will exhibit resonance among multiple equivalent Lewis structures that satisfy the octet rule? (**a**) only one ion (**b**) NO_2^- and CO_3^{2-} (**c**) NO_2^-,and SO_4^{2-} (**d**) CO_3^{2-} and SO_4^{2-} (**e**) all three ions

EP 8.18 Which of the following is expected to be the dominant Lewis structure for the CF_2 molecule?

(**a**)

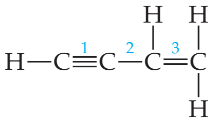
(**b**)

(**c**)

(**d**)

EP 8.19 In which of these molecules or ions is there only one lone pair of electrons on the central sulfur atom? (**a**) SF_4 (**b**) SF_6 (**c**) SOF_4 (**d**) SF_2 (**e**) SO_4^{2-}

EP 8.20 Of the three numbered bonds in the structure shown here, bond number ________ is the strongest and bond number ________ is the longest. (**a**) 1, 3 (**b**) 2, 3 (**c**) 2, 1 (**d**) 3, 2 (**e**) 1, 2



$\mathrm{H{-}C\overset{1}{\equiv}C\overset{2}{-}\overset{H}{C}\overset{3}{=}\underset{H}{\overset{H}{C}}}$

Exercises

Visualizing Concepts

8.1 For each of these Lewis symbols, indicate the group in the periodic table in which the element X belongs: [Section 8.1]

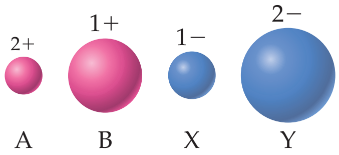
(**a**)

(**b**)

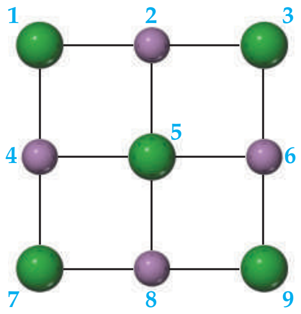
(**c**)

8.2 Illustrated are four ions—A, B, X, and Y—showing their relative ionic radii. The ions shown in red carry positive charges: a 2+ charge for A and a 1+ charge for B. Ions shown in blue carry negative charges: a 1− charge for X and a 2− charge for Y.

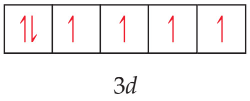
(**a**) Which combinations of these ions produce ionic compounds where there is a 1:1 ratio of cations and anions? (**b**) Among the combinations in part (a), which leads to the ionic compound having the largest lattice energy? [Section 8.2]



8.3 A portion of a two-dimensional "slab" of NaCl(s) is shown here (see Figure 8.4) in which the ions are numbered. (**a**) Which colored balls must represent sodium ions? (**b**) Which colored balls must represent chloride ions? (**c**) Consider ion 5. How many attractive electrostatic interactions are shown for it? (**d**) Consider ion 5. How many repulsive interactions are shown for it? (**e**) Is the sum of the attractive interactions in part (c) larger or smaller than the sum of the repulsive interactions in part (d)? (**f**) If this pattern of ions were extended indefinitely in two dimensions, would the lattice energy be positive or negative? [Section 8.2]

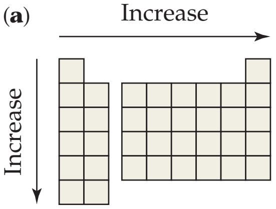


8.4 The orbital diagram that follows shows the valence electrons for a 3+ ion of an element. (**a**) What is the element? (**b**) What is the electron configuration of an atom of this element? [Section 8.2]

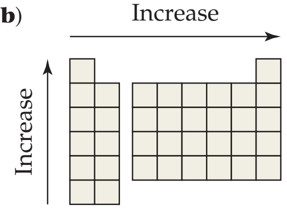


8.5 Which of the following charts shows the general periodic trends for the electronegativities of the representative elements? [Section 8.4]

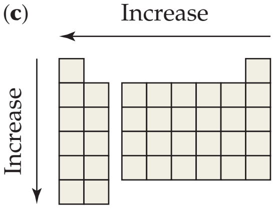
(**a**)



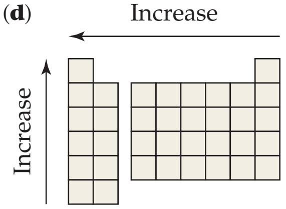
(**b**)



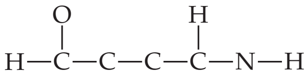
(**c**)



(**d**)

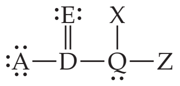


8.6 A molecule with formula C_4H_3NO has the connectivity shown in the figure. After the Lewis structure of the molecule is completed, how many of each of the following are there in the molecule: (**a**) single bonds, (**b**) double bonds, (**c**) triple bonds, (**d**) nonbonding pairs? [Sections 8.3 and 8.5]



$$\mathrm{H{-}\overset{O}{\overset{|}{C}}{-}C{-}C{-}\overset{H}{\overset{|}{C}}{-}N{-}H}$$

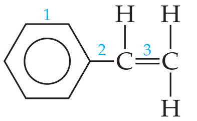
8.7 In the Lewis structure shown here, A, D, E, Q, X, and Z represent elements in the first two rows of the periodic table. Identify all six elements so that the formal charges of all atoms are zero. [Section 8.5]



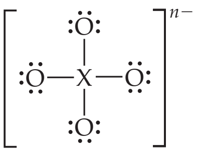
8.8 Incomplete Lewis structures for the nitrous acid molecule, HNO_2, and the nitrite ion, NO_2^-, are shown here. (**a**) Complete each Lewis structure by adding electron pairs as needed. (**b**) Is the formal charge on N the same or different in these two species? (**c**) Would either HNO_2 or NO_2^- be expected to exhibit resonance? (**d**) Would you expect the N═O bond in HNO_2 to be longer, shorter, or the same length as the N—O bonds in NO_2^-? [Sections 8.5, 8.6, and 8.8]

$$\mathrm{H{-}O{-}N{=}O} \qquad \mathrm{O{-}N{=}O}$$

8.9 The molecule shown here is *styrene*, C_8H_8, a benzene derivative that is used to make a number of polymers, including polystyrene. The shorthand notation for the benzene ring (described in Section 8.6) is used. Three of the carbon–carbon bonds are numbered in the structure. (**a**) Which of the three bonds is the strongest? (**b**) Which of the three bonds is the longest? (**c**) Which of the three bonds is best described as halfway between a single and a double bond? [Sections 8.6 and 8.8]



8.10 Consider the Lewis structure for the polyatomic oxyanion shown here, where X is an element from the third period (Na—Ar). By changing the overall charge, n, from 1− to 2− to 3− we get three different polyatomic ions. For each of these ions (**a**) identify the central atom, X; (**b**) determine the formal charge of the central atom, X; (**c**) draw a Lewis structure that makes the formal charge on the central atom equal to zero. [Sections 8.5, 8.6, and 8.7]



Lewis Symbols (Section 8.1)

8.11 (**a**) True or false: An element's number of valence electrons is the same as its atomic number. (**b**) How many valence electrons does a nitrogen atom possess? (**c**) An atom has the electron configuration $1s^2 2s^2 2p^6 3s^2 3p^2$. How many valence electrons does the atom have?

8.12 (**a**) True or false: The hydrogen atom is most stable when it has a full octet of electrons. (**b**) How many electrons must a sulfur atom gain to achieve an octet in its valence shell? (**c**) If an atom has the electron configuration $1s^22s^22p^3$, how many electrons must it gain to achieve an octet?

8.13 Consider the element silicon, Si. (**a**) Write its electron configuration. (**b**) How many valence electrons does a silicon atom have? (**c**) Which subshells hold the valence electrons?

8.14 (**a**) Write the electron configuration for the element titanium, Ti. How many valence electrons does this atom possess? (**b**) Hafnium, Hf, is also found in group 4B. Write the electron configuration for Hf. **(c)** Ti and Hf behave as though they possess the same number of valence electrons. Which of the subshells in the electron configuration of Hf behave as valence orbitals? Which behave as core orbitals?

8.15 Write the Lewis symbol for atoms of each of the following elements: (**a**) Al, (**b**) Br, **(c)** Ar, (**d**) Sr.

8.16 What is the Lewis symbol for each of the following atoms or ions: (**a**) K, (**b**) As, (**c**) Sn^{2+}, (**d**) N^{3-}?

Ionic Bonding (Section 8.2)

8.17 (**a**) Using Lewis symbols, diagram the reaction between magnesium and oxygen atoms to give the ionic substance MgO. (**b**) How many electrons are transferred? (**c**) Which atom loses electrons in the reaction?

8.18 (**a**) Use Lewis symbols to represent the reaction that occurs between Ca and F atoms. (**b**) What is the chemical formula of the most likely product? (**c**) How many electrons are transferred? (**d**) Which atom loses electrons in the reaction?

8.19 Predict the chemical formula of the ionic compound formed between the following pairs of elements: (**a**) Al and F, (**b**) K and S, (**c**) Y and O, (**d**) Mg and N.

8.20 Which ionic compound is expected to form from combining the following pairs of elements: (**a**) barium and fluorine, (**b**) cesium and chlorine, (**c**) lithium and nitrogen, (**d**) aluminum and oxygen?

8.21 Write the electron configuration for each of the following ions, and determine which ones possess noble-gas configurations: (**a**) Rb^+ (**b**) Rh^{3+} (**c**) P^{3-} (**d**) Sc^{3+} (**e**) S^{2-} (**f**) V^{2+}.

8.22 Write electron configurations for the following ions, and determine which have noble-gas configurations: (**a**) Sn^{2+} (**b**) I^- (**c**) Ta^{3+} (**d**) Se^{2-} (**e**) Pd^{2+} (**f**) Cu^{2+}.

8.23 (**a**) Is the process that defines lattice energy endothermic or exothermic? (**b**) Write the chemical equation that represents the process of lattice energy for the case of NaCl. (**c**) Would you expect salts like NaCl, which have singly charged ions, to have larger or smaller lattice energies compared to salts like CaO, which are composed of doubly charged ions?

8.24 NaCl and KF have the same crystal structure. The only difference between the two is the distance that separates cations and anions. (**a**) The lattice energies of NaCl and KF are given in Table 8.1. Based on the lattice energies, would you expect the Na—Cl or the K—F distance to be longer? (**b**) Use the ionic radii given in Figure 7.8 to estimate the Na—Cl and K—F distances.

8.25 The substances NaF and CaO are isoelectronic (have the same number of valence electrons). (**a**) What are the charges on each of the cations in each compound? (**b**) What are the charges of each of the anions in each compound? (**c**) Without looking up lattice energies, which compound is predicted to have the larger lattice energy? (**d**) Using the lattice energies in Table 8.1, predict the lattice energy of ScN.

8.26 (**a**) Does the lattice energy of an ionic solid increase or decrease (i) as the charges of the ions increase, (ii) as the sizes of the ions increase? (**b**) Arrange the following substances not listed in Table 8.1 according to their expected lattice energies, listing them from lowest lattice energy to the highest: MgS, KI, GaN, LiBr.

8.27 Consider the ionic compounds KF, NaCl, NaBr, and LiCl. (**a**) Use ionic radii (Figure 7.8) to estimate the cation–anion distance for each compound. (**b**) Based on your answer to part (**a**), arrange these four compounds in order of decreasing lattice energy. (**c**) Check your predictions in part (b) with the experimental values of lattice energy from Table 8.1. Are the predictions from ionic radii correct?

8.28 Which of the following trends in lattice energy is due to differences in ionic radii: (**a**) NaCl > RbBr > CsBr, (**b**) BaO > KF, (**c**) SrO > $SrCl_2$?

8.29 Energy is required to remove two electrons from Ca to form Ca^{2+}, and energy is required to add two electrons to O to form O^{2-}. Yet CaO is stable relative to the free elements. Which statement is the best explanation? (**a**) The lattice energy of CaO is large enough to overcome these processes. (**b**) CaO is a covalent compound, and these processes are irrelevant. (**c**) CaO has a higher molar mass than either Ca or O. (**d**) The enthalpy of formation of CaO is small. (**e**) CaO is stable to atmospheric conditions.

8.30 List the individual steps used in constructing a Born–Haber cycle for the formation of BaI_2 from the elements. Which of the steps would you expect to be exothermic?

8.31 Use data from Appendix C, Figure 7.11, and Figure 7.13 to calculate the lattice energy of KI.

8.32 (**a**) Based on the lattice energies of $MgCl_2$ and $SrCl_2$ given in Table 8.1, what is the range of values that you would expect for the lattice energy of $CaCl_2$? (**b**) Using data from Appendix C, Figure 7.11, Figure 7.13, and the value of the second ionization energy for Ca, 1145 kJ/mol, calculate the lattice energy of $CaCl_2$.

Covalent Bonding, Electronegativity, and Bond Polarity (Sections 8.3 and 8.4)

8.33 (**a**) State whether or not the bonding in each substance is likely to be covalent: (i) iron, (ii) sodium chloride, (iii) water, (iv) oxygen, (v) argon. (**b**) A substance XY, formed from two different elements, boils at −33 °C. Is XY likely to be a covalent or an ionic substance?

8.34 Which of these elements are unlikely to form covalent bonds: S, H, K, Ar, Si?

8.35 Using Lewis symbols and Lewis structures, diagram the formation of $SiCl_4$ from Si and Cl atoms, showing valence-shell electrons. (**a**) How many valence electrons does Si have initially? (**b**) How many valence electrons does each Cl have initially? (**c**) How many valence electrons surround the Si in the $SiCl_4$ molecule? (**d**) How many valence electrons surround each Cl in the $SiCl_4$ molecule? (**e**) How many bonding pairs of electrons are in the $SiCl_4$ molecule?

8.36 Use Lewis symbols and Lewis structures to diagram the formation of PF_3 from P and F atoms, showing valence-shell electrons. (**a**) How many valence electrons does P have initially? (**b**) How many valence electrons does each F have initially? (**c**) How many valence electrons surround the P in the PF_3 molecule? (**d**) How many valence electrons surround each F in the PF_3 molecule? (**e**) How many bonding pairs of electrons are in the PF_3 molecule?

8.37 (**a**) Construct a Lewis structure for O_2 in which each atom achieves an octet of electrons. (**b**) How many bonding electrons are in the structure? (**c**) Would you expect the O—O bond in O_2 to be shorter or longer than the O—O bond in compounds that contain an O—O single bond? Explain.

8.38 (**a**) Construct a Lewis structure for hydrogen peroxide, H_2O_2, in which each atom achieves an octet of electrons. (**b**) How many bonding electrons are between the two oxygen atoms? (**c**) Do you expect the O—O bond in H_2O_2 to be longer or shorter than the O—O bond in O_2? Explain.

8.39 Which of the following statements about electronegativity is or are *true*?

- (**i**) The alkali metals are the family with the largest electronegativity values.
- (**ii**) The numerical values for electronegativity have no units.
- (**iii**) Electronegativity is the ability of an atom in a molecule to attract electron density toward itself.

8.40 Place the following pairs of elements in order from smallest to largest difference in electronegativity: K and F, S and O, Br and I, Ca and Se, Li and Cl.

8.41 Using only the periodic table as your guide, select the most electronegative atom in each of the following sets: (**a**) Na, Mg, K, Ca (**b**) P, S, As, Se (**c**) Be, B, C, Si (**d**) Zn, Ge, Ga, As.

8.42 By referring only to the periodic table, select (**a**) the most electronegative element in group 6A; (**b**) the least electronegative element in the group Al, Si, P; (**c**) the most electronegative element in the group Ga, P, Cl, Na; (**d**) the element in the group K, C, Zn, F that is most likely to form an ionic compound with Ba.

8.43 Which of the following bonds are polar: (**a**) B—F, (**b**) Cl—Cl, (**c**) Se—O, (**d**) H—I? Which is the more electronegative atom in each polar bond?

8.44 Arrange the bonds in each of the following sets in order of increasing polarity: (**a**) C—F, O—F, B—F (**b**) O—Cl, S—Br, C—P (**c**) C—S, B—F, N—O.

8.45 (**a**) From the data in Table 8.2, calculate the effective charges on the H and Br atoms of the HBr molecule in units of the electronic charge, *e*. (**b**) If you were to put HBr under very high pressure, so that its bond length decreased significantly, would its dipole moment increase, decrease, or stay the same, if you assume that the effective charges on the atoms do not change?

8.46 The bromine monofluoride molecule, BrF, has a bond length of 1.76 Å and a dipole moment of 1.29 D. (**a**) Which atom of the molecule is expected to have a negative charge? (**b**) In units of the electronic charge, *e*, what is the magnitude of the charge on the Br atom in BrF?

8.47 In the following pairs of binary compounds, determine which one is a molecular substance and which one is an ionic substance. Use the appropriate naming convention (for ionic or molecular substances) to assign a name to each compound: (**a**) SiF_4 and LaF_3 (**b**) $FeCl_2$ and $ReCl_6$ (**c**) $PbCl_4$ and RbCl.

8.48 In the following pairs of binary compounds, determine which one is a molecular substance and which one is an ionic substance. Use the appropriate naming convention (for ionic or molecular substances) to assign a name to each compound: (**a**) $TiCl_4$ and CaF_2 (**b**) ClF_3 and VF_3 (**c**) $SbCl_5$ and AlF_3.

Lewis Structures; Resonance Structures (Sections 8.5 and 8.6)

8.49 Draw Lewis structures that satisfy the octet rule for the following molecules and ions: (**a**) CF_4, (**b**) NO^+, (**c**) SO_3^{2-} (**d**) HCN (H and N are both bonded to C), (**e**) BF_4^-, (**f**) HOCl.

8.50 Write Lewis structures that satisfy the octet rule for the following molecules and ions: (**a**) NH_4^+, (**b**) C_2F_4 (the two C atoms are bonded to one another), (**c**) $COCl_2$ (the Cl atoms are bonded to C), (**d**) HSO_3^- (H is bonded to one of the O atoms), (**e**) HNC (H and C are both bonded to N), (**f**) ClO_3^-.

8.51 Which one of these statements about formal charge is *true*? (**a**) Formal charge is the same as oxidation number. (**b**) To determine the dominant Lewis structure, you should minimize formal charge. (**c**) Formal charge takes into account the different electronegativities of the atoms in a molecule (**d**) Formal charge is most useful for ionic compounds. (**e**) Formal charge is used in calculating the dipole moment of a diatomic molecule.

8.52 (**a**) Draw the dominant Lewis structure for the phosphorus trifluoride molecule, PF_3. (**b**) Determine the oxidation numbers of the P and F atoms. (**c**) Determine the formal charges of the P and F atoms.

8.53 Write Lewis structures that obey the octet rule for each of the following, and assign oxidation numbers and formal charges to each atom: (**a**) OCS, (**b**) $SOCl_2$ (S is the central atom), (**c**) BrO_3^-, (**d**) $HClO_2$ (H is bonded to O).

8.54 For each of the following ions of nitrogen and oxygen, write a single Lewis structure that obeys the octet rule, and calculate the oxidation numbers and formal charges on all the atoms: (**a**) NO^+, (**b**) NO_2^-, (**c**) NO_2^+. (**d**) Arrange these ions in order of increasing N—O bond length.

8.55 (**a**) Draw a single Lewis structure that satisfies the octet rule for sulfur dioxide, SO_2. (**b**) With what allotrope of oxygen is it isoelectronic? (**c**) Are there multiple equivalent resonance structures for this molecule? (**d**) What would you predict for the lengths of the bonds in SO_2 relative to S—O single bonds and double bonds?

8.56 Consider the formate ion, HCO_2^-, which is the anion formed when formic acid loses an H^+ ion. The H and the two O atoms are bonded to the central C atom. (**a**) Draw a single Lewis structure that satisfies the octet rule for this ion. (**b**) Are resonance structures needed to describe the structure? (**c**) Would you predict that the C—O bond lengths in the formate ion would be longer or shorter relative to those in CO_2?

8.57 Predict the ordering, from shortest to longest, of the bond lengths in CO, CO_2, and CO_3^{2-}.

8.58 Based on Lewis structures, predict the ordering, from shortest to longest, of N—O bond lengths in NO^+, NO_2^-, and NO_3^-.

8.59 Consider a Lewis structure for SO_3 that satisfies the octet rule. Which of the following statements is or are *true*?

- (**i**) SO_3 has three equivalent resonance structures.
- (**ii**) There are one shorter and two longer S—O bond lengths in SO_3.
- (**iii**) The S atom in SO_3 has a nonzero formal charge.

8.60 Which of the following statements about benzene, C_6H_6, is or are *true*?

- (**i**) Benzene has two equivalent resonance structures.
- (**ii**) There are no nonbonding pairs in the Lewis structure for benzene.
- (**iii**) Benzene has three short and three long C—C bonds.

Exceptions to the Octet Rule (Section 8.7)

8.61 (**a**) Which of these compounds is an exception to the octet rule: carbon dioxide, water, ammonia, phosphorus trifluoride, or arsenic pentafluoride? (**b**) Which of these compounds or ions is an exception to the octet rule: nitrogen dioxide, borohydride (BH_4^-), borazine ($B_3N_3H_6$, which is analogous to benzene with alternating B and N in the ring), or boron trichloride?

8.62 Fill in the blank with the appropriate numbers for both electrons and bonds (considering that single bonds are counted as one, double bonds as two, and triple bonds as three).

(**a**) Fluorine has ________ valence electrons and makes ________ bond(s) in compounds.

(**b**) Oxygen has ________ valence electrons and makes ________ bond(s) in compounds.

(**c**) Nitrogen has ________ valence electrons and makes ________ bond(s) in compounds.

(**d**) Carbon has ________ valence electrons and makes ________ bond(s) in compounds.

8.63 Draw the dominant Lewis structures for these chlorine–oxygen molecules/ions: $ClO, ClO^-, ClO_2^-, ClO_3^-, ClO_4^-$. Which of these do not obey the octet rule?

8.64 Which of the following statements is or are *true*?

(**i**) Any molecule that doesn't satisfy the octet rule is hypervalent.

(**ii**) Elements in the third row of the periodic table can form hypervalent molecules, whereas those in the second row cannot.

(**iii**) Any molecule in which there are four bonds to the central atom satisfies the octet rule.

8.65 Draw the Lewis structures for each of the following ions or molecules. Identify those in which the octet rule is not obeyed; state which atom in each compound does not follow the octet rule; and state, for those atoms, how many electrons surround these atoms: (**a**) PH_3, (**b**) AlH_3, (**c**) N_3^-, (**d**) CH_2Cl_2, (**e**) SnF_6^{2-}.

8.66 Draw the Lewis structures for each of the following molecules or ions. Identify instances where the octet rule is not obeyed; state which atom in each compound does not follow the octet rule; and state how many electrons surround these atoms: (**a**) NO, (**b**) BF_3, (**c**) ICl_2^-, (**d**) $OPBr_3$ (the P is the central atom), (**e**) XeF_4.

8.67 In the vapor phase, $BeCl_2$ exists as a discrete molecule. (**a**) Draw the Lewis structure of this molecule, using only single bonds. Does this Lewis structure satisfy the octet rule? (**b**) What other resonance structures are possible that satisfy the octet rule? (**c**) On the basis of the formal charges, which Lewis structure is expected to be dominant for $BeCl_2$?

8.68 (**a**) Describe the molecule xenon trioxide, XeO_3, using four possible Lewis structures, one each with zero, one, two, or three Xe—O double bonds. (**b**) Do any of these resonance structures satisfy the octet rule for every atom in the molecule? (**c**) Do any of the four Lewis structures have multiple resonance structures? If so, how many resonance structures do you find? (**d**) Which of the Lewis structures in part (a) yields the most favorable formal charges for the molecule?

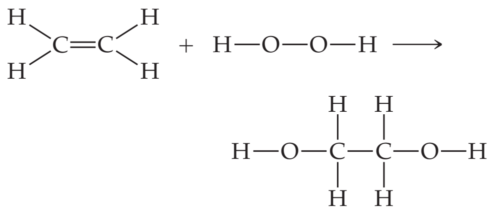
8.69 There are many Lewis structures you could draw for sulfuric acid, H_2SO_4 (each H is bonded to an O). (**a**) What Lewis structure(s) would you draw to satisfy the octet rule? (**b**) What Lewis structure(s) would you draw to minimize formal charge?

8.70 Some chemists believe that satisfaction of the octet rule should be the top criterion for choosing the dominant Lewis structure of a molecule or ion. Other chemists believe that achieving the best formal charges should be the top criterion. Consider the dihydrogen phosphate ion, $H_2PO_4^-$, in which the H atoms are bonded to O atoms. (**a**) What is the predicted dominant Lewis structure if satisfying the octet rule is the top criterion? (**b**) What is the predicted dominant Lewis structure if achieving the best formal charges is the top criterion?

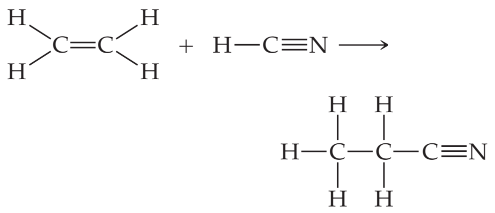
Strengths and Lengths of Covalent Bonds (Section 8.8)

8.71 Using Table 8.3, estimate ΔH for each of the following gas-phase reactions (note that lone pairs on atoms are not shown):

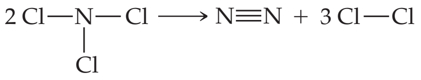
(**a**)



(**b**)



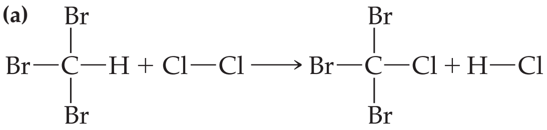
(**c**)



$2\,\mathrm{Cl{-}}\underset{\mathrm{Cl}}{\underset{|}{\mathrm{N}}}\mathrm{{-}Cl} \longrightarrow \mathrm{N{\equiv}N} + 3\,\mathrm{Cl{-}Cl}$

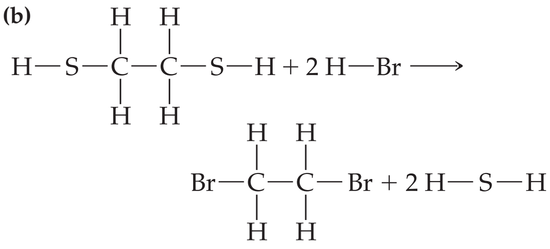
8.72 Using Table 8.3, estimate ΔH for the following gas-phase reactions:

(**a**)



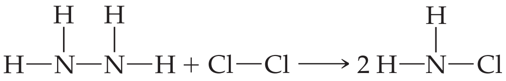
$\mathrm{Br{-}}\overset{\mathrm{Br}}{\overset{|}{\underset{\mathrm{Br}}{\underset{|}{\mathrm{C}}}}}\mathrm{{-}H} + \mathrm{Cl{-}Cl} \longrightarrow \mathrm{Br{-}}\overset{\mathrm{Br}}{\overset{|}{\underset{\mathrm{Br}}{\underset{|}{\mathrm{C}}}}}\mathrm{{-}Cl} + \mathrm{H{-}Cl}$

(**b**)



$\mathrm{H{-}S{-}}\overset{\mathrm{H}}{\overset{|}{\underset{\mathrm{H}}{\underset{|}{\mathrm{C}}}}}\mathrm{{-}}\overset{\mathrm{H}}{\overset{|}{\underset{\mathrm{H}}{\underset{|}{\mathrm{C}}}}}\mathrm{{-}S{-}H} + 2\,\mathrm{H{-}Br} \longrightarrow \mathrm{Br{-}}\overset{\mathrm{H}}{\overset{|}{\underset{\mathrm{H}}{\underset{|}{\mathrm{C}}}}}\mathrm{{-}}\overset{\mathrm{H}}{\overset{|}{\underset{\mathrm{H}}{\underset{|}{\mathrm{C}}}}}\mathrm{{-}Br} + 2\,\mathrm{H{-}S{-}H}$

(**c**)



$\mathrm{H{-}}\overset{\mathrm{H}}{\overset{|}{\mathrm{N}}}\mathrm{{-}}\overset{\mathrm{H}}{\overset{|}{\mathrm{N}}}\mathrm{{-}H} + \mathrm{Cl{-}Cl} \longrightarrow 2\,\mathrm{H{-}}\overset{\mathrm{H}}{\overset{|}{\mathrm{N}}}\mathrm{{-}Cl}$

8.73 State whether each of these statements is true or false. (**a**) The longer the bond, the larger the bond enthalpy. (**b**) C—C bonds are stronger than C—H bonds. (**c**) A typical single-bond length is in the 5–10 Å range. (**d**) Energy is released when a chemical bond is broken. (**e**) Energy is stored in chemical bonds.

8.74 State whether each of these statements is true or false. (**a**) A carbon–carbon triple bond is shorter than a carbon–carbon single bond. (**b**) There are exactly six bonding electrons in the O_2 molecule. (**c**) The C—O bond in carbon monoxide is shorter than the C—O bond in carbon dioxide. (**d**) The O—O bond in ozone is shorter than the O—O bond in O_2. (**e**) The average bond enthalpies of all triple bonds are the same value regardless of what atoms are involved.

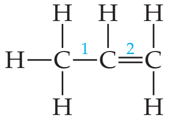
8.75 We can define average bond enthalpies and bond lengths for ionic bonds, just like we have for covalent bonds. Which ionic bond is predicted to be stronger, Na—Cl or Ca—O?

8.76 We can define average bond enthalpies and bond lengths for ionic bonds, just like we have for covalent bonds. Which ionic bond is predicted to have the smaller bond enthalpy, Li—F or Cs—F?

8.77 A new compound is made that has a C—C bond length of 1.15 Å. Is this bond likely to be a single, double, or triple C—C bond?

8.78 A new compound is made that has an N—N bond length of 1.26 Å. Is this bond likely to be a single, double, or triple N—N bond?

8.79 The molecule shown is *propylene*, C_3H_6, which is an important feedstock for the polymer industry. The two carbon–carbon bonds in the molecule are numbered. (**a**) Does propylene have multiple equivalent resonance structures? (**b**) Which carbon–carbon bond is the stronger? (**c**) Which carbon–carbon bond is longer?

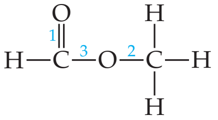


8.80 The molecule shown is *methyl formate*, $C_2H_4O_2$, the simplest example of an organic *ester*. The three carbon–oxygen bonds in the molecule are numbered. Which of the following statements is or are *true*?

(**i**) Bond 1 is the strongest carbon–oxygen bond.

(**ii**) Bond 1 is longer than bond 2.

(**iii**) The length of bond 3 is closer in value to that of bond 2 than to that of bond 1.



Additional Exercises

8.81 Consider the lattice energies of the following group 2A compounds: BeH_2, 3205 kJ/mol; MgH_2, 2791 kJ/mol; CaH_2, 2410 kJ/mol; SrH_2, 2250 kJ/mol; BaH_2, 2121 kJ/mol. (**a**) What is the oxidation number of H in these compounds? (**b**) Assuming that all of these compounds have the same three-dimensional arrangement of ions in the solid, which of these compounds has the shortest cation–anion distance? (**c**) Consider BeH_2. Does it require 3205 kJ of energy to break one mole of the solid into its ions, or does breaking up one mole of solid into its ions release 3205 kJ of energy? (**d**) The lattice energy of ZnH_2 is 2870 kJ/mol. Considering the trend in lattice enthalpies in the group 2A compounds, predict which group 2A element is most similar in ionic radius to the Zn^{2+} ion.

8.82 Based on data in Table 8.1, estimate (within 30 kJ/mol) the lattice energy for (**a**) LiBr, (**b**) CsBr, (**c**) $CaCl_2$.

8.83 An ionic substance of formula MX has a lattice energy of 3000 kJ/mol (to one significant figure). Based on the data in Table 8.1, is the charge on the ion M likely to be 1+, 2+, or 3+?

8.84 The ionic compound CaO crystallizes with the same structure as sodium chloride (Figure 8.3). (**a**) In this structure, how many O^{2-} are in contact with each Ca^{2+} ion (*Hint:* Remember the pattern of ions shown in Figure 8.3 repeats over and over again in all three directions.) (**b**) Would energy be consumed or released if a crystal of CaO was converted to a collection of widely separated Ca—O ion pairs? (**c**) From the ionic radii given in Figure 7.8, calculate the potential energy of a single Ca—O ion pair that is just touching (the magnitude of electronic charge is given on the inside back cover). (**d**) Calculate the energy of a mole of such pairs. How does this compare to the lattice energy of CaO? (**e**) What factor do you think accounts for most of the discrepancy between the energies in part (d)—the bonding in CaO is more covalent than ionic, or the electrostatic interactions in a crystal lattice are more complicated than those in a single ion pair?

8.85 Construct a Born–Haber cycle for the formation of the hypothetical compound $NaCl_2$, where the sodium ion has a 2+ charge (the second ionization energy for sodium is given in Table 7.2). (**a**) How large would the lattice energy need to be for the formation of $NaCl_2$ to be exothermic? (**b**) If we were to estimate the lattice energy of $NaCl_2$ to be roughly equal to that of $MgCl_2$ (2326 kJ/mol from Table 8.1), what value would you obtain for the standard enthalpy of formation, ΔH_f°, of $NaCl_2$?

8.86 A classmate of yours is convinced that they know everything about electronegativity. (**a**) In the case of atoms X and Y having different electronegativities, they say, the diatomic molecule X—Y must be polar. Is your classmate correct? (**b**) Your classmate says that the farther the two atoms are apart in a bond, the larger the dipole moment will be. Is your classmate correct?

8.87 Consider the collection of nonmetallic elements O, P, Te, I, and B. (**a**) Which two would form the most polar single bond? (**b**) Which two would form the longest single bond? (**c**) Which two would be likely to form a compound of formula XY_2? (**d**) Which combinations of elements would likely yield a compound of empirical formula X_2Y_3?

8.88 The substance chlorine monoxide, ClO(*g*), is important in atmospheric processes that lead to depletion of the ozone layer. The ClO molecule has an experimental dipole moment of 1.24 D, and the Cl—O bond length is 1.60 Å. (**a**) Determine the magnitude of the charges on the Cl and O atoms in units of the electronic charge, *e*. (**b**) Based on the electronegativities of the elements, which atom would you expect to have a partial negative charge in the ClO molecule? (**c**) Using formal charges as a guide, propose the dominant Lewis structure for the molecule. (**d**) The anion ClO^- exists. What is the formal charge on the Cl for the dominant Lewis structure for ClO^-?

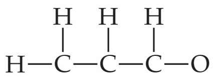
8.89 (**a**) Using the electronegativities of Br and Cl, estimate the partial charges on the atoms in the Br—Cl molecule using the procedure discussed in the *A Closer Look* box in Section 8.5. (**b**) Using these partial charges and the atomic radii given in Figure 7.8, estimate the dipole moment of the molecule. (**c**) The measured dipole moment of BrCl is 0.57 D. If you assume the bond length in BrCl is the sum of the atomic radii, what are the partial charges on the atoms in BrCl using the experimental dipole moment?

8.90 A major challenge in implementing the "hydrogen economy" is finding a safe, lightweight, and compact way of storing hydrogen for use as a fuel. The hydrides of light metals are attractive for hydrogen storage because they can store a high weight percentage of hydrogen in a small volume. For example, $NaAlH_4$ can release 5.6% of its mass as H_2 upon decomposing to NaH(*s*), Al(*s*), and H_2(*g*). $NaAlH_4$ possesses both covalent bonds, which hold polyatomic anions together, and ionic bonds. (**a**) Write a balanced equation for the decomposition of $NaAlH_4$. (**b**) Which element in $NaAlH_4$ is the most electronegative? Which one is the least electronegative? (**c**) Based on electronegativity differences, predict the identity of the polyatomic anion. Draw a Lewis structure for this ion. (**d**) What is the formal charge on hydrogen in the polyatomic ion?

8.91 Structures A, B, and C show the connectivity of the atoms in three different molecules that are isomers of C_3H_4O. By completing the Lewis structures of these molecules, complete the information in the following table:

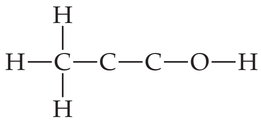
	Isomer A	Isomer B	Isomer C
Number of single bonds			
Number of double bonds			
Number of triple bonds			
Number of nonbonding pairs			

A



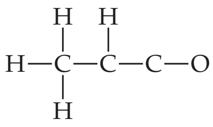
$H-\overset{H}{C}-\overset{H}{C}-\overset{H}{C}-O$

B



$H-\overset{H}{\underset{H}{C}}-C-C-O-H$

C



$H-\overset{H}{\underset{H}{C}}-\overset{H}{C}-C-O$

8.92 The *triiodide* ion, I_3^-, exists, whereas the corresponding ion with fluorine, F_3^-, does not. The I_3^- ion has a linear structure in which two outer I atoms are each bonded to a central I atom. Although I_3^- is a known ion, F_3^- is not. (**a**) Draw the Lewis structure for I_3^-, assuming that there are two I—I single bonds in the ion. (**b**) Does I_3^- satisfy the octet rule? (**c**) Which of the following statements about the existence of I_3^- versus the nonexistence of F_3^- is or are true? (i) The Lewis structure of I_3^- shows 12 electrons around the central I atom. (ii) Elements from the second row of the periodic table generally do not form hypervalent molecules and ions. (iii) An I atom can form a hypervalent molecule or ion more readily than an F atom because of the larger size of the I atom.

8.93 Calculate the formal charge on the indicated atom in each of the following molecules or ions: (**a**) the central oxygen atom in O_3, (**b**) phosphorus in PF_6^-, (**c**) nitrogen in NO_2, (**d**) iodine in ICl_3, (**e**) chlorine in $HClO_4$ (hydrogen is bonded to O).

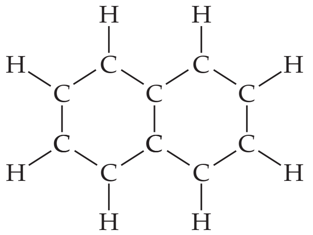
8.94 The hypochlorite ion, ClO^-, is the active ingredient in bleach. The perchlorate ion, ClO_4^-, is a main component of rocket propellants. Draw Lewis structures for both ions. (**a**) What is the formal charge of Cl in the hypochlorite ion? (**b**) What is the formal charge of Cl in the perchlorate ion, assuming the Cl—O bonds are all single bonds? (**c**) What is the oxidation number of Cl in the hypochlorite ion? (**d**) What is the oxidation number of Cl in the perchlorate ion, assuming the Cl—O bonds are all single bonds? (**e**) In a redox reaction, which ion would you expect to be more easily reduced?

8.95 The following three Lewis structures can be drawn for N_2O:

$$:N\equiv N-\underset{\cdot\cdot}{\ddot{O}}: \longleftrightarrow :\underset{\cdot\cdot}{\ddot{N}}-N\equiv O: \longleftrightarrow :\ddot{N}=N=\ddot{O}:$$

(**a**) Using formal charges, which of these three resonance forms is likely to be the most important? (**b**) The N—N bond length in N_2O is 1.12 Å, slightly longer than a typical N≡N bond; and the N—O bond length is 1.19 Å, slightly shorter than a typical N═O bond (see Table 8.4). Based on these data, which resonance structure best represents N_2O?

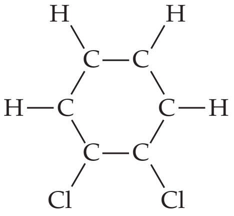
8.96 Mothballs are composed of naphthalene, $C_{10}H_8$, a molecule that consists of two six-membered rings of carbon fused along an edge, as shown in this incomplete Lewis structure:



(**a**) Draw all of the resonance structures of naphthalene. How many are there? (**b**) Do you expect the C—C bond lengths in the molecule to be similar to those of C—C single bonds, C═C double bonds, or intermediate between C—C single and C═C double bonds? (**c**) Not all of the C—C bond lengths in naphthalene are equivalent. Based on your resonance structures, how many C—C bonds in the molecule do you expect to be shorter than the others?

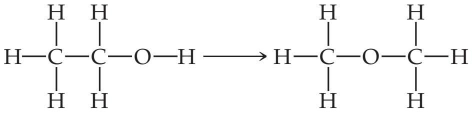
8.97 (**a**) Triazine, $C_3H_3N_3$, is like benzene except that in triazine every other C—H group is replaced by a nitrogen atom. Draw the Lewis structure(s) for the triazine molecule. (**b**) Estimate the carbon–nitrogen bond distances in the ring.

8.98 *Ortho*-Dichlorobenzene, $C_6H_4Cl_2$, is obtained when two of the adjacent hydrogen atoms in benzene are replaced with Cl atoms. A skeleton of the molecule is shown here. (**a**) Complete a Lewis structure for the molecule using bonds and electron pairs as needed. (**b**) Are there any resonance structures for the molecule? If so, sketch them. (**c**) Are the resonance structures in (a) and (b) equivalent to one another as they are in benzene?



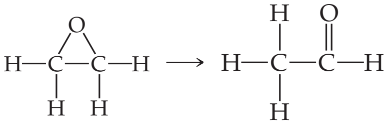
8.99 Two compounds are isomers if they have the same chemical formula but different arrangements of atoms. Use Table 8.3 to estimate ΔH for each of the following gas-phase isomerization reactions and indicate which isomer has the lower enthalpy.

(a)



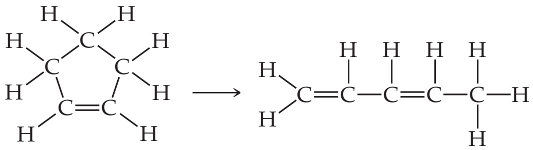
Ethanol Dimethyl ether

(b)



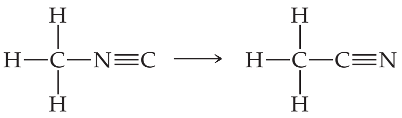
Ethylene oxide Acetaldehyde

(c)



Cyclopentene Pentadiene

(d)



Methyl isocyanide Acetonitrile

8.100 (**a**) Draw the Lewis structure for hydrogen peroxide, H_2O_2. (**b**) From the data presented in Table 8.3, what is the weakest bond in hydrogen peroxide? (**c**) Hydrogen peroxide is sold commercially as an aqueous solution in brown bottles to protect it from light. Calculate the longest wavelength of light that has sufficient energy to break the weakest bond in hydrogen peroxide.

8.101 The electron affinity of oxygen is −141 kJ/mol, corresponding to the reaction

$$O(g) + e^- \longrightarrow O^-(g)$$

The lattice energy of $K_2O(s)$ is 2238 kJ/mol. Use these data along with data in Appendix C and Figure 7.11 to calculate the "second electron affinity" of oxygen, corresponding to the reaction

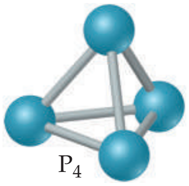
$$O^-(g) + e^- \longrightarrow O^{2-}(g)$$

8.102 You and a partner are asked to complete a lab entitled "Oxides of Ruthenium" that is scheduled to extend over two lab periods. The first lab, which is to be completed by your partner, is devoted to carrying out compositional analysis. In the second lab, you are to determine melting points. Upon going to lab you find two unlabeled vials, one containing a soft yellow substance and the other a black powder. You also find the following notes in your partner's notebook—*Compound 1*: 76.0% Ru and 24.0% O (by mass), *Compound 2*: 61.2% Ru and 38.8% O (by mass). (**a**) What is the empirical formula for Compound 1? (**b**) What is the empirical formula for Compound 2? Upon determining the melting points of these two compounds, you find that the yellow compound melts at 25 °C, while the black powder does not melt up to the maximum temperature of your apparatus, 1200 °C. (**c**) What is the identity of the yellow compound? (**d**) What is the identity of the black compound? (**e**) Which compound is molecular? (**f**) Which compound is ionic?

8.103 The compound chloral hydrate, known in detective stories as knockout drops, is composed of 14.52% C, 1.83% H, 64.30% Cl, and 13.35% O by mass, and has a molar mass of 165.4 g/mol. (**a**) What is the empirical formula of this substance? (**b**) What is the molecular formula of this substance? (**c**) Draw the Lewis structure of the molecule, assuming that the Cl atoms bond to a single C atom and that there are a C—C bond and two C—O bonds in the compound.

8.104 Under special conditions, sulfur reacts with anhydrous liquid ammonia to form a binary compound of sulfur and nitrogen. The compound is found to consist of 69.6% S and 30.4% N. Measurements of its molecular mass yield a value of 184.3 g/mol. The compound occasionally detonates on being struck or when heated rapidly. The sulfur and nitrogen atoms of the molecule are joined in a ring. All the bonds in the ring are of the same length. (**a**) Calculate the empirical and molecular formulas for the substance. (**b**) Write Lewis structures for the molecule, based on the information you are given. (*Hint:* You should find a relatively small number of dominant Lewis structures.) (**c**) Predict the bond distances between the atoms in the ring. (*Note:* The S—S distance in the S_8 ring is 2.05 Å.) (**d**) The enthalpy of formation of the compound is estimated to be 480 kJ/mol^{-1}. ΔH_f° of S(*g*) is 222.8 kJ/mol. Estimate the average bond enthalpy in the compound.

8.105 A common form of elemental phosphorus is the tetrahedral P_4 molecule, where all four phosphorus atoms are equivalent:

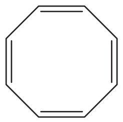


At room temperature phosphorus is a solid. (**a**) Are there any lone pairs of electrons in the P_4 molecule? (**b**) How many P—P bonds are there in the molecule? (**c**) Draw a Lewis structure for a linear P_4 molecule that satisfies the octet rule. Does this molecule have resonance structures? (**d**) On the basis of formal charges, which is more stable, the linear molecule or the tetrahedral molecule?

Design an Experiment

You have learned that the resonance of benzene, C_6H_6, gives the compound special stability.

(**a**) By using data in Appendix C, compare the heat of combustion of 1.0 mol $C_6H_6(g)$ to the heat of combustion of 3.0 mol acetylene, $C_2H_2(g)$, Which has the greater fuel value, 1.0 mol $C_6H_6(g)$ or 3.0 mol $C_2H_2(g)$? Are your calculations consistent with benzene being especially stable? (**b**) Repeat part (a), with the appropriate molecules, for toluene ($C_6H_6CH_3$), a derivative of benzene that has a —CH_3 group in place of one H. (**c**) Another reaction you can use to compare molecules is *hydrogenation*, the reaction of a carbon–carbon double bond with H_2 to make a C—C single bond and two C—H single bonds. The experimental heat of hydrogenation of benzene to make cyclohexane (C_6H_{10}, a six-membered ring with 6 C—C single bonds and 12 C—H bonds) is 208 kJ/mol. The experimental heat of hydrogenation of cyclohexene (C_6H_{10}, a six-membered ring with one C═C double bond, 5 C—C single bonds, and 10 C—H bonds) to make cyclohexane is 120 kJ/mol. Show how these data can provide you with an estimate of the *resonance stabilization energy* of benzene. (**d**) Are the bond lengths or angles in benzene, compared to other hydrocarbons, sufficient to decide if benzene exhibits resonance and is especially stable? Discuss. (**e**) Consider cyclooctatetraene, C_8H_8, which has the octagonal structure shown below.



Cyclooctatetraene

What experiments or calculations could you perform to determine whether cyclooctatetraene exhibits resonance?

9

MOLECULAR GEOMETRY AND BONDING THEORIES

▲ **COLOR OF TOMATOES.** The hydrocarbon molecule *lycopene*, $C_{40}H_{56}$, gives tomatoes their red color as well as some of their nutrient properties. The color of lycopene is due to its arrangement of alternating single and double bonds, which gives the molecule the ability to absorb visible light.

Lewis structures help us understand the compositions of molecules and their covalent bonds. However, Lewis structures do *not* show one of the most important aspects of molecules—their overall shapes. The shape and size of molecules—sometimes referred to as *molecular architecture*—are defined by the angles and distances between the nuclei of the component atoms.

In this chapter, our first goal is to understand the relationship between two-dimensional Lewis structures and three-dimensional molecular shapes. We show the intimate relationship between the number of electrons in a molecule and the overall shape it adopts. We then examine more closely the nature of covalent bonds. The lines used to depict bonds in Lewis structures provide important clues about the orbitals that molecules use in bonding. By examining these orbitals, we can gain a greater understanding of the behavior of molecules. Mastering the material in this chapter will help you in later discussions of the physical and chemical properties of substances.

WHAT'S AHEAD

9.1 ▶ Molecular Shapes Draw and describe the three-dimensional structures of molecules.

9.2 ▶ The VSEPR Model Predict molecular geometries using the *valence-shell electron-pair repulsion* (*VSEPR*) model, which is based on Lewis structures and the repulsions between regions of high electron density.

9.3 ▶ Molecular Shape and Molecular Polarity Determine whether a molecule is *polar* or *nonpolar* by analyzing its geometry and the types of bonds it contains.

9.4 ▶ Covalent Bonding and Orbital Overlap Use *valence-bond theory* to explain the distribution of electrons in molecules containing covalent bonds.

9.5 ▶ Hybrid Orbitals Illustrate how the orbitals of one atom mix with one another, or *hybridize*, to create *hybrid orbitals*, which can then overlap to form covalent bonds.

9.6 ▶ Multiple Bonds Learn how atomic orbitals overlap in multiple ways to produce *sigma* (σ) and *pi* (π) bonds between atoms. Single bonds consist of one σ bond; multiple bonds involve one sigma and one or more π bonds. Describe how the presence of π bonds affects the shape and conformational flexibility of organic molecules.

9.7 ▶ Molecular Orbitals Examine a more sophisticated treatment of bonding called *molecular-orbital theory*, which introduces the concepts of *bonding* and *antibonding molecular orbitals*.

9.8 ▶ Molecular-Orbital Description of Period 2 Diatomic Molecules Extend the concepts of molecular-orbital theory to construct *energy-level diagrams* for second-row diatomic molecules.

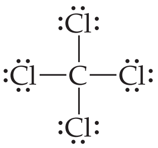
9.1 | Molecular Shapes

Learning Objectives

When you finish Section 9.1, you should be able to:

- Describe, sketch, and name the three-dimensional shapes of AB_n molecules.
- Identify the characteristic bond angles associated with the shapes of AB_n molecules.
- Demonstrate that trigonal-pyramidal and bent geometries are obtained by removing B atoms from a tetrahedral AB_4 molecule.

In Chapter 8 we used Lewis structures to account for the formulas of covalent compounds. (Section 8.5) Lewis structures, however, do *not* indicate the shapes of molecules; they simply show the number and types of bonds. For example, the Lewis structure of CCl_4 tells us only that four Cl atoms are bonded to a central C atom:



The Lewis structure is drawn with the atoms all in the same plane. As shown in **Figure 9.1**, however, the actual three-dimensional arrangement has the Cl atoms at the corners of a *tetrahedron*, a geometric object with four corners and four faces, each an equilateral triangle.

The shape of a molecule is determined by its **bond angles**, the angles made by the lines joining the nuclei of the atoms in the molecule. The bond angles of a molecule, together with the bond lengths (Section 8.8), define the shape and size of the molecule. In Figure 9.1, you should be able to see that there are six Cl—C—Cl bond angles in CCl_4, all of which have the same value. That bond angle, 109.5°, is characteristic of a tetrahedron. In addition, all four C—Cl bonds have the same length (1.78 Å). Thus, the shape and size of CCl_4 are completely described by stating that the molecule is tetrahedral with C—Cl bonds of length 1.78 Å. To draw the three-dimensional structure of a molecule on paper, chemists use a convention shown in Figure 9.1: Regular lines imply the bond is in the plane of the paper, a heavy wedge is used to show that the bond is coming out of the paper toward you, and the dashed wedge is used to show that the bond is pointing away from you, through the back of the paper.

We begin our discussion of molecular shapes with molecules (and ions) that, like CCl_4, have a single central atom bonded to two or more atoms of the same type. Such molecules have the general formula AB_n in which the central atom A is bonded to n B atoms. Both CO_2 and H_2O are AB_2 molecules, for example, whereas SO_3 and NH_3 are AB_3 molecules, and so on.

The number of shapes possible for AB_n molecules depends on the value of n. Those commonly found for AB_2 and AB_3 molecules are shown in **Figure 9.2**. An AB_2 molecule must be either *linear* (bond angle $= 180°$) or *bent* (bond angle $\neq 180°$). For AB_3 molecules, the two most common shapes place the B atoms at the vertices of an equilateral triangle. If the A atom lies in the same plane as the B atoms, the shape is called *trigonal planar*. If the A atom lies above the plane of the B atoms, the shape is called *trigonal*

Go Figure In the space-filling model, what determines the relative sizes of the spheres?

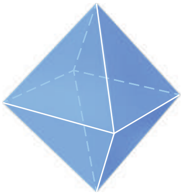
pyramidal (a pyramid with an equilateral triangle as its base). Some AB_3 molecules, such as ClF_3, are *T-shaped*, a relatively unusual shape also shown in Figure 9.2. The atoms lie in one plane with two B—A—B angles of about 90°, and a third angle close to 180°.

Quite remarkably, the shapes of most AB_n molecules can be derived from just five basic geometric arrangements, shown in **Figure 9.3**. All of these are highly symmetric arrangements of the n B atoms around the central A atom. We have already seen the first three shapes: linear, trigonal planar, and tetrahedral. The trigonal-bipyramid shape for AB_5 can be thought of as a trigonal planar AB_3 arrangement with two additional atoms, one above and one below the equilateral triangle. The octahedral shape for AB_6 has all six B atoms at the same distance from atom A, with 90° B—A—B angles between all neighboring B atoms. Its symmetric shape (and its name) are derived from the *octahedron*, a geometric solid with eight faces, all of which are equilateral triangles.



Octahedron

Some of the shapes we have already discussed are *not* among the five shapes in Figure 9.3. In Figure 9.2, for example, neither the bent shape of the SO_2 molecule nor the trigonal-pyramidal shape of the NF_3 molecule is among the shapes in Figure 9.3. However, we can derive additional shapes, such as bent and trigonal pyramidal, by starting with one

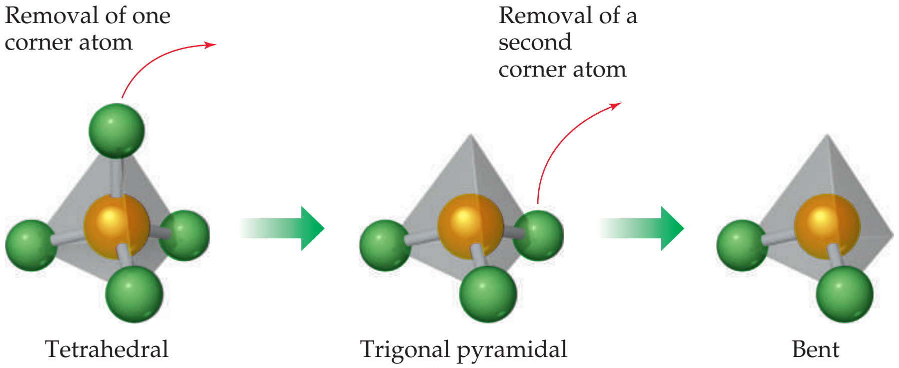
Go Figure In going from the tetrahedral shape to the bent shape, does it matter which two of the atoms we choose to remove?



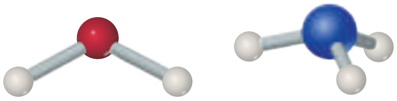
▲ **Figure 9.4 Derivatives of the tetrahedral molecular shape.**

of our five basic arrangements. Starting with a tetrahedron, for example, we can remove atoms successively from the vertices, as shown in Figure 9.4. When an atom is removed from one vertex of a tetrahedron, the remaining AB_3 fragment has a trigonal-pyramidal geometry. When a second atom is removed, the remaining AB_2 fragment has a bent geometry.

Why do most AB_n molecules have shapes related to those shown in Figure 9.3? Can we predict these shapes? When A is a representative element (one from the *s* block or *p* block of the periodic table), we can answer these questions by using the **valence-shell electron-pair repulsion (VSEPR) model**. Although the name is rather imposing, the model is quite simple and has useful predictive capabilities.

Self-Assessment Exercises

SAE 9.1 Water, H_2O, and ammonia, NH_3, have the molecular shapes shown here. What are the names of the shapes of H_2O and NH_3? (**a**) linear, trigonal planar (**b**) linear, trigonal pyramidal (**c**) bent, trigonal planar (**d**) bent, trigonal pyramidal



SAE 9.2 The nitrate ion, NO_3^-, has a trigonal-planar shape. Which of the following statements about the nitrate ion is *false*? (**a**) All four atoms in the nitrate ion lie in the same plane. (**b**) The O—N—O bond angles in the nitrate ion are 109.5°. (**c**) There are AB_3 molecules that have a different shape than that of the nitrate ion. (**d**) The three O atoms in the nitrate ion lie on the vertices of an equilateral triangle.

SAE 9.3 Which of the following statements about AB_n molecules is or are *true*?

(**i**) The two characteristic shapes for an AB_2 molecule are linear and bent.
(**ii**) In a tetrahedral AB_4 molecule, all of the B—A—B angles are 109.5°.
(**iii**) Removing one B atom from a tetrahedral AB_4 molecule leads to a trigonal pyramidal AB_3 molecule.

(**a**) Only one of the statements is true. (**b**) Statements i and ii are true. (**c**) Statements i and iii are true. (**d**) Statements ii and iii are true. (**e**) All three statements are true.

Learning Objectives

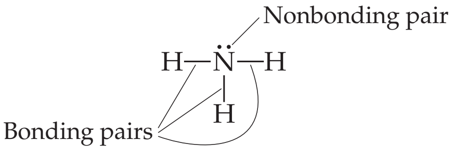
When you finish Section 9.2, you should be able to:

- Determine the electron-domain geometry around the central atom for an AB_n molecule or ion ($n = 2 - 6$).
- Predict the geometries of molecules with two, three, or four electron domains around the central atom using the VSEPR model.
- Predict the geometries of molecules with five or six electron domains around the central atom using the VSEPR model.
- Use the VSEPR model to predict the bond angles in molecules with more than one central atom.

9.2 | The VSEPR Model

Imagine tying two identical balloons together at their ends. As shown in Figure 9.5, the two balloons naturally orient themselves to point away from each other; that is, they try to “get out of each other’s way” as much as possible. If we add a third balloon, the balloons orient themselves toward the vertices of an equilateral triangle, and if we add a fourth balloon, they adopt a tetrahedral shape. Thus, an optimum geometry exists for each number of balloons.

In some ways, the electrons in molecules behave like these balloons. We have seen that a single covalent bond is formed between two atoms when a pair of electrons occupies the space between the atoms. (Section 8.3) A *bonding pair* of electrons thus defines a region in which the electrons are most likely to be found. We refer to such a region as an **electron domain**. Likewise, a *nonbonding pair* (or *lone pair*) of electrons, which was also discussed in Section 8.3, defines an electron domain that is located principally on one atom. For example, the Lewis structure of NH_3 has four electron domains around the central nitrogen atom (three bonding pairs, represented as usual by short lines, and one nonbonding pair, represented by dots):



Each multiple bond in a molecule also constitutes a single electron domain. Thus, the following resonance structure for O_3 has three electron domains around the central oxygen atom (a single bond, a double bond, and a nonbonding pair of electrons):

$$:\ddot{\underset{..}{O}}-\ddot{O}=\ddot{\underset{..}{O}}$$

In general, *each nonbonding pair, single bond, or multiple bond produces a single electron domain around the central atom in a molecule*.

The VSEPR model is based on the idea that electron domains are negatively charged and therefore repel one another. Like the balloons in Figure 9.5, electron domains try to stay out of one another's way:

> *The best arrangement of a given number of electron domains is the one that minimizes the repulsions among them.*

In fact, the analogy between electron domains and balloons is so close that the same preferred geometries are found in both cases. Like the balloons in Figure 9.5, two electron domains orient *linearly*, three domains orient in a *trigonal-planar* fashion, and four orient *tetrahedrally*. These arrangements, together with those for five- and six-electron domains, are summarized in **Table 9.1**. Notice that the geometries in Table 9.1 are the same as those in Figure 9.3. The observation that there is an optimum shape for each specific number of electron domains around the central atom leads to the most important assumption of the VSEPR model:

> *The shapes of different* AB_n *molecules or ions depend on the number of electron domains surrounding the central atom.*

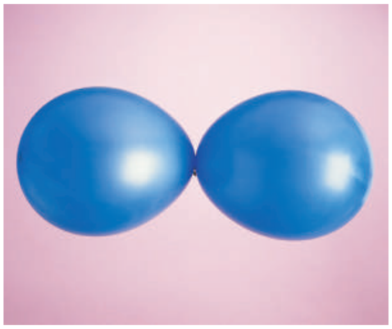
The arrangement of the electron domains about the central atom of an AB_n molecule or ion is called its **electron-domain geometry**. In contrast, the **molecular geometry** is the arrangement of *only the atoms* in a molecule or ion—any nonbonding pairs in the molecule are *not* part of the description of the molecular geometry.

Applying the VSEPR Model to Determine Molecular Shapes

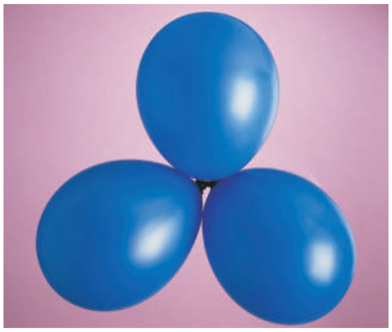
In determining the shape of any molecule, we first use the VSEPR model to predict the electron-domain geometry. From knowing how many of the domains are due to nonbonding pairs, we can then predict the molecular geometry. When all the electron domains in a molecule arise from bonds, the molecular geometry is identical to the electron-domain geometry. When one or more domains involve nonbonding pairs of electrons, however, we must remember that *the molecular geometry involves only electron domains due to bonds* even though the nonbonding pairs contribute to the electron-domain geometry.

Go Figure

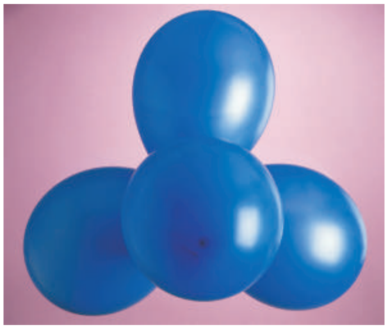
What arrangement do you think six balloons would adopt?



Two balloons: Linear



Three balloons: Trigonal planar



Four balloons: Tetrahedral

▲ **Figure 9.5** **A balloon analogy for electron domains.**

TABLE 9.1 **Electron-Domain Geometries as a Function of Number of Electron Domains**

Number of Electron Domains	Arrangement of Electron Domains	Electron-Domain Geometry	Predicted Bond Angles
2		Linear	180°
3		Trigonal planar	120°
4		Tetrahedral	109.5°
5		Trigonal bipyramidal	120° 90°
6		Octahedral	90°

How to Predict the Shapes of Molecules and Ions Using the VSEPR Model

1. Draw the Lewis structure of the molecule or ion (Section 8.5), then count the number of electron domains around the central atom. Each nonbonding electron pair, each single bond, each double bond, and each triple bond counts as one electron domain.
2. From the number of electron domains around the central atom, use Table 9.1 to determine the *electron-domain geometry* of the molecule or ion.
3. Use the arrangement of the bonded atoms to determine the *molecular geometry*.

Table 9.2 summarizes the possible molecular geometries when an AB_n molecule has four or fewer electron domains about A. These geometries are important because they include all the shapes usually seen in molecules or ions that obey the octet rule.

TABLE 9.2 Electron-Domain and Molecular Geometries for Two, Three, and Four Electron Domains around a Central Atom

Number of Electron Domains	Electron-Domain Geometry	Bonding Domains	Nonbonding Domains	Molecular Geometry	Example
2	 Linear	2	0	 Linear	$\underset{\cdot\cdot}{\ddot{O}}=C=\underset{\cdot\cdot}{\ddot{O}}$
3	 Trigonal planar	3	0	 Trigonal planar			2	1	 Bent	4	 Tetrahedral	4	0	 Tetrahedral			3	1	 Trigonal pyramidal			2	2	 Bent	
Figure 9.6 shows how to use the three steps in the VSEPR model to predict the geometry of the NH_3 molecule. The three bonds and one nonbonding pair in the Lewis structure tell us we have four electron domains. Thus, from Table 9.1, the electron-domain geometry of NH_3 is tetrahedral. We know from the Lewis structure that one electron domain is due to a nonbonding pair, which occupies one of the four vertices of the tetrahedron. In determining the molecular geometry, we consider only the three N—H bond domains, which leads to a trigonal-pyramidal geometry. The situation is just like the middle drawing in Figure 9.4 in which removing one atom from a tetrahedral molecule results in a trigonal-pyramidal molecule. As a result, the trigonal-pyramidal molecular geometry is a direct consequence of the tetrahedral electron-domain geometry.

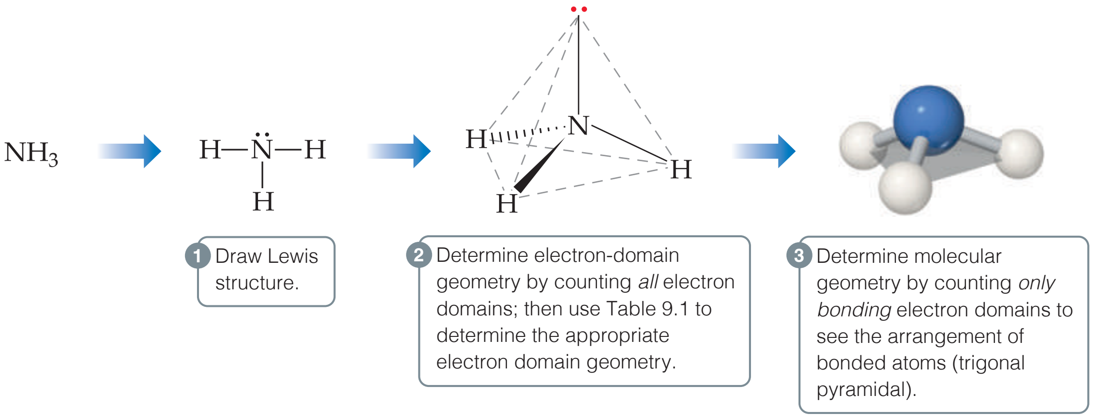
Because the trigonal-pyramidal molecular geometry is based on a tetrahedral electron-domain geometry, the ideal bond angles are 109.5°. As we will soon see, bond angles deviate from ideal values when the surrounding atoms and electron domains are not identical.

As one more example, let's determine the shape of the CO_2 molecule. Its Lewis structure reveals two electron domains (each one a double bond) around the central carbon:

$$\underset{\cdot\cdot}{\ddot{O}}=C=\underset{\cdot\cdot}{\ddot{O}}$$

Go Figure

Can a tetrahedral electron-domain geometry result in a trigonal-planar molecular geometry?



① Draw Lewis structure.

② Determine electron-domain geometry by counting *all* electron domains; then use Table 9.1 to determine the appropriate electron domain geometry.

③ Determine molecular geometry by counting *only* *bonding* electron domains to see the arrangement of bonded atoms (trigonal pyramidal).

▲ **Figure 9.6 Determining the molecular geometry of NH_3.**

Two electron domains orient in a linear electron-domain geometry (Table 9.1). Because neither domain is a nonbonding pair of electrons, the molecular geometry is also linear, and the O—C—O bond angle is 180°.

Sample Exercise 9.1

Using the VSEPR Model

Use the VSEPR model to predict the molecular geometry of (**a**) O_3, (**b**) $SnCl_3^-$.

SOLUTION

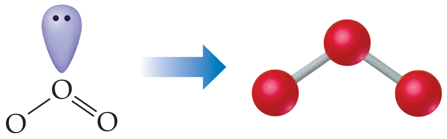
Analyze We are given the molecular formulas of a molecule and a polyatomic ion, both conforming to the general formula AB_n and both having a central atom from the *p* block of the periodic table. (For O_3, the A and B atoms are all oxygen atoms.)

Plan To predict the molecular geometries, we draw their Lewis structures and count electron domains around the central atom to get the electron-domain geometry. We then obtain the molecular geometry from the arrangement of the domains that are due to bonds.

Solve

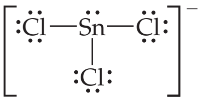
(**a**) We can draw two resonance structures for O_3:

Because of resonance, the bonds between the central O atom and the outer O atoms are of equal length. In both resonance structures, the central O atom is bonded to the two outer O atoms and has one nonbonding pair. Thus, there are three electron domains about the central O atoms. (Remember that a double bond counts as a single electron domain.) The arrangement of three electron domains is trigonal planar (Table 9.1). Two of the domains are from bonds, and one is due to a nonbonding pair. So, the molecular geometry is bent with an ideal bond angle of 120° (Table 9.2).

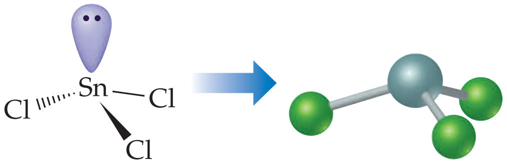


Comment As this example illustrates, when a molecule exhibits resonance, any one of the resonance structures can be used to predict the molecular geometry.

(**b**) The Lewis structure for $SnCl_3^-$ is:



The central Sn atom is bonded to the three Cl atoms and has one nonbonding pair; thus, we have four electron domains, meaning a tetrahedral electron-domain geometry (Table 9.1) with one vertex occupied by a nonbonding pair of electrons. A tetrahedral electron-domain geometry with three bonding and one nonbonding domains leads to a trigonal-pyramidal molecular geometry (Table 9.2).

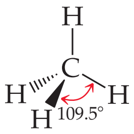


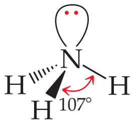
▶ **Practice Exercise**

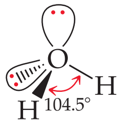
Predict the electron-domain and molecular geometries for (**a**) $SeCl_2$, (**b**) CO_3^{2-}.

Effect of Nonbonding Electrons and Multiple Bonds on Bond Angles

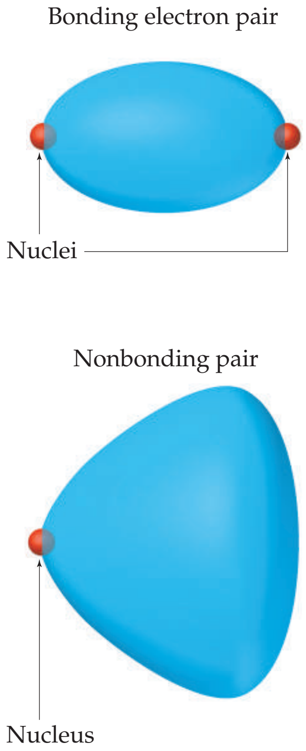
We can refine the VSEPR model to explain slight distortions from the ideal geometries summarized in Table 9.2. For example, methane (CH_4), ammonia (NH_3), and water (H_2O) all have four electron domains around the central atom. As a result, each has a tetrahedral electron-domain geometry, but each has a different distribution of bonding and nonbonding electron domains—namely, four bonding and zero nonbonding for CH_4, three bonding and one nonbonding for NH_3, and two bonding and two nonbonding for H_2O. Experiments show that their bond angles differ slightly:





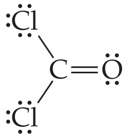


Methane, which has a tetrahedral molecular geometry, has the usual tetrahedral angles of 109.5°. For NH_3 and H_2O, however, the bond angles decrease as the number of nonbonding electron pairs increases. A bonding pair of electrons is attracted by both nuclei of the bonded atoms, but a nonbonding pair is attracted primarily by only one nucleus. Because a nonbonding pair experiences less nuclear attraction, its electron domain is spread out more in space than is the electron domain for a bonding pair (**Figure 9.7**). Nonbonding electron pairs therefore take up more space than bonding pairs; in essence, they act as larger and fatter balloons in our analogy of Figure 9.5. As a result, *electron domains for nonbonding electron pairs exert greater repulsive forces on adjacent electron domains and tend to compress bond angles*.

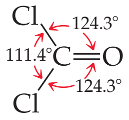


▲ **Figure 9.7 Relative sizes of bonding and nonbonding electron domains.** Nonbonding electron domains are more spread out in space than are bonding domains.

We face a similar situation when we compare the electron domains that result from single and multiple bonds. Because multiple bonds contain a higher electronic-charge density than single bonds, multiple bonds also represent enlarged electron domains. Consider the Lewis structure of *phosgene*, Cl_2CO:



Because three electron domains surround the central atom, we might expect a trigonal-planar geometry with 120° bond angles. The double bond, however, repels other domains more strongly than does a single bond, reducing the Cl—C—Cl bond angle to 111.4°:



In general, *electron domains for multiple bonds exert a greater repulsive force on adjacent electron domains than do electron domains for single bonds*.

Molecules with Expanded Valence Shells

Recall that atoms from period 3 and beyond may be surrounded by more than four electron pairs—they can have more than an octet of electrons around the central atom. (Section 8.7) We consider here the electron-domain and molecular geometries that result when the central atom has five or six electron domains around it. The results are summarized in **Table 9.3**.

The most stable electron-domain geometry for five electron domains is the trigonal bipyramid (two trigonal pyramids sharing a base). Unlike the other arrangements we have seen, the electron domains in a trigonal bipyramid can point toward two geometrically distinct types of positions. The three positions that lie at the vertices of an equilateral triangle are called *equatorial positions*. The remaining two positions, which are above

TABLE 9.3 Electron-Domain and Molecular Geometries for Five and Six Electron Domains around a Central Atom

Number of Electron Domains	Electron-Domain Geometry	Bonding Domains	Nonbonding Domains	Molecular Geometry	Example
5	 Trigonal bipyramidal	5	0	 Trigonal bipyramidal	PCl_5
		4	1	 Seesaw	SF_4
		3	2	 T-shaped	ClF_3
		2	3	 Linear	XeF_2
6	 Octahedral	6	0	 Octahedral	SF_6
		5	1	 Square pyramidal	BrF_5
		4	2	 Square planar	XeF_4

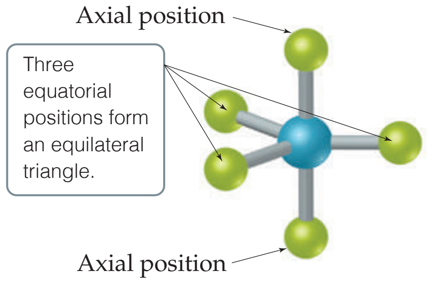
and below the plane of the equilateral triangle, are called *axial positions* (**Figure 9.8**). Each domain in an axial position (an *axial domain*) makes a 90° angle with any domain in an equatorial position (an *equatorial domain*). Each equatorial domain makes a 120° angle with either of the other two equatorial domains and a 90° angle with either axial domain.

Suppose a molecule has five electron domains, and there are one or more nonbonding pairs. Will the domains from the nonbonding pairs occupy axial or equatorial positions? To answer this question, we must determine which location minimizes the total repulsions between domains. Repulsion between two domains is much greater when they are situated 90° from each other than when they are at 120°. An equatorial domain is 90° from only two other domains (the axial domains), but an axial domain is 90° from *three* other domains (the equatorial domains). Hence, an equatorial domain experiences less repulsion than an axial domain. Because the domains from nonbonding pairs exert larger repulsions than those from bonding pairs, nonbonding domains *always* occupy the equatorial positions in a trigonal bipyramid.

The most stable electron-domain geometry for six electron domains is the *octahedron*. An octahedron is a polyhedron with six vertices and eight faces, each an equilateral triangle. An atom with six electron domains around it can be visualized as being at the center of the octahedron with the electron domains pointing toward the six vertices, as shown in Table 9.3. All the bond angles are 90°, and all six vertices are equivalent. Therefore, if an atom has five bonding electron domains and one nonbonding domain, we can put the nonbonding domain at any of the six vertices of the octahedron. The result is always a *square-pyramidal* molecular geometry—four of the outer atoms lie at the vertices of a square and the fifth outer atom occupies a position above the plane of the square. When there are two nonbonding electron domains, their repulsions are minimized by pointing them toward opposite sides of the octahedron, producing a *square-planar* molecular geometry, as shown in Table 9.3.

Go Figure

What is the bond angle formed by an axial position, the central atom, and any equatorial position?



▲ **Figure 9.8 Trigonal-bipyramidal geometry.** The outer atoms occupy two types of positions.

Sample Exercise 9.2

Molecular Geometries of Molecules with Expanded Valence Shells

Use the VSEPR model to predict the molecular geometry of (**a**) SF_4, (**b**) IF_5.

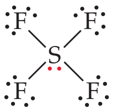
SOLUTION

Analyze The molecules are of the AB_n type with a central *p*-block atom.

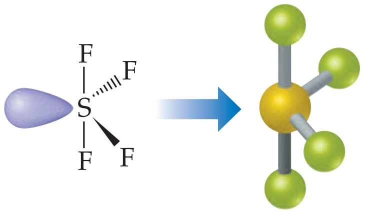
Plan We first draw Lewis structures and then use the VSEPR model to determine the electron-domain geometry and molecular geometry.

Solve

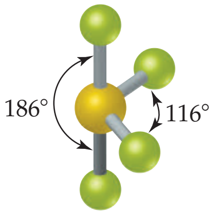
(**a**) The Lewis structure for SF_4 is:



The sulfur has five electron domains around it: four from the S—F bonds and one from the nonbonding pair. Each domain points toward a vertex of a trigonal bipyramid. The domain from the nonbonding pair will point toward an equatorial position. The four bonds point toward the remaining four positions, resulting in a molecular geometry that is described as seesaw-shaped:

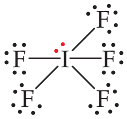


Comment The experimentally observed structure is shown on the right. We can infer that the nonbonding electron domain occupies an equatorial position, as predicted. The axial and equatorial S—F bonds are slightly bent away from the nonbonding domain, suggesting that the bonding domains are "pushed" by the nonbonding domain, which exerts a greater repulsion (Figure 9.7).



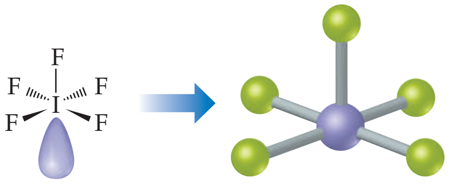
Solve

(**b**) The Lewis structure of IF_5 is:



Continued

The iodine has six electron domains around it, one of which is nonbonding. The electron-domain geometry is therefore octahedral, with one position occupied by the nonbonding pair, and the molecular geometry is *square pyramidal* (Table 9.3):



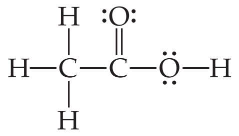
Comment Because the nonbonding domain is larger than the bonding domains, we predict that the four F atoms in the base of the pyramid will be tipped up slightly toward the top F atom. Experimentally, we find that the angle between the base atoms and the top F atom is 82°, smaller than the ideal 90° angle of an octahedron.

▶ Practice Exercise

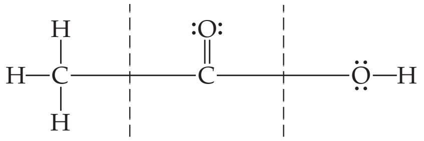
Predict the electron-domain and molecular geometries of (**a**) BrF_3, (**b**) SF_5^+.

Shapes of Larger Molecules

Although the molecules and ions we have considered contain only a single central atom, the VSEPR model can be extended to more complex molecules, such as acetic acid:



We can use the VSEPR model to predict the geometry about each atom that is bonded to two or more other atoms:

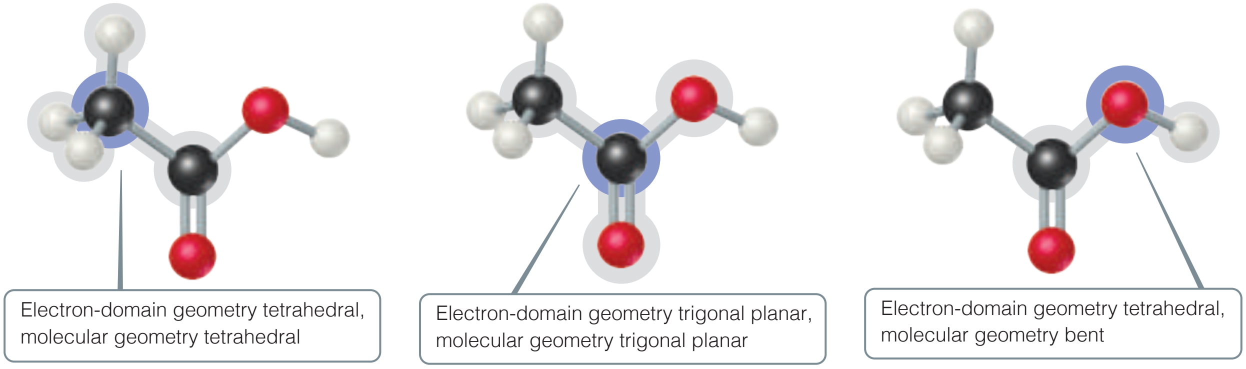


Number of electron domains	4	3	4
Electron-domain geometry	Tetrahedral	Trigonal planar	Tetrahedral
Predicted bond angles	109.5°	120°	109.5°

The C on the left has four electron domains (all bonding), so the electron-domain and molecular geometries around that atom are both tetrahedral. The central C has three electron domains (counting the double bond as one domain), making both the electron-domain and the molecular geometries trigonal planar. The O on the right has four electron domains (two bonding, two nonbonding), so its electron-domain geometry is tetrahedral and its molecular geometry is bent. The bond angles about the central C atom and the O atom are expected to deviate slightly from the ideal values of 120° and 109.5° because of the spatial demands of multiple bonds and nonbonding electron pairs.

Our analysis of the acetic acid molecule is summarized in **Figure 9.9**.

Go Figure In the actual structure of acetic acid, which bond angle is expected to be the smallest?



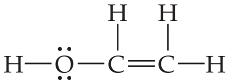
Electron-domain geometry tetrahedral, molecular geometry tetrahedral
Electron-domain geometry trigonal planar, molecular geometry trigonal planar
Electron-domain geometry tetrahedral, molecular geometry bent

▲ **Figure 9.9 The electron-domain and molecular geometries around the three central atoms of acetic acid, CH_3COOH.**

Sample Exercise 9.3

Predicting Bond Angles

Eyedrops for dry eyes usually contain a water-soluble polymer called *poly(vinyl alcohol)*, which is based on the unstable organic molecule *vinyl alcohol*:



$$H-\underset{\cdot\cdot}{\overset{\cdot\cdot}{O}}-\overset{\overset{H}{|}}{C}=\overset{\overset{H}{|}}{C}-H$$

Predict the approximate values for the H—O—C and O—C—C bond angles in vinyl alcohol.

SOLUTION

Analyze We are given a Lewis structure and asked to determine two bond angles.

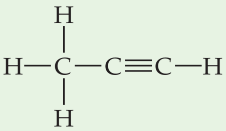
Plan To predict a bond angle, we determine the number of electron domains surrounding the middle atom in the angle. The ideal angle corresponds to the electron-domain geometry around the atom. The angle will be compressed somewhat by nonbonding electrons or multiple bonds.

Solve In H—O—C, the O atom has four electron domains (two bonding, two nonbonding). The electron-domain geometry around O is therefore tetrahedral, which gives an ideal angle of 109.5°. The H—O—C angle is compressed somewhat by the nonbonding pairs, so we expect this angle to be slightly less than 109.5°.

To predict the O—C—C bond angle, we examine the middle atom in the angle. In the molecule, there are three atoms bonded to this C atom and no nonbonding pairs, and so it has three electron domains about it. The predicted electron-domain geometry is trigonal planar, resulting in an ideal bond angle of 120°. Because of the larger size of the C═C domain, the actual bond angle is 126°, slightly greater than 120°.

▶ Practice Exercise

Predict the H—C—H and C—C—C bond angles in *propyne*:



$$H-\underset{\underset{H}{|}}{\overset{\overset{H}{|}}{C}}-C\equiv C-H$$

Self-Assessment Exercises

9.3 | Molecular Shape and Molecular Polarity

Now that we have a sense of the shapes that molecules adopt and why they do so, we can further explore some topics that we first discussed in Section 8.4—namely, *bond polarity* and *dipole moments*. Recall that bond polarity is a measure of how equally the electrons in a bond are shared between the two atoms of the bond. As the difference in electronegativity between the two atoms increases, so does the bond polarity. (Section 8.4) We saw that the dipole moment of a diatomic molecule is a measure of the amount of charge separation in the molecule.

Learning Objectives

When you finish Section 9.3, you should be able to:

- Explain how the overall polarity of a molecule depends on its shape and the polarities of its bonds.
- Predict whether a molecule is polar or nonpolar based on its molecular geometry.

For a molecule consisting of more than two atoms, *the dipole moment depends on both the polarities of the individual bonds and the geometry of the molecule*. For each bond in the molecule, we consider the **bond dipole**, which is the dipole moment due only to the two atoms in that bond. In the linear CO_2 molecule, for example, shown in Figure 9.10(**a**), each C═O bond is polar. And because the C═O bonds are identical, the bond dipoles are equal in magnitude. A plot of the molecule's electron density clearly shows that the individual bonds are polar, but what can we say about the *overall* dipole moment of the molecule?

Bond dipoles and dipole moments are *vector quantities*; that is, they have both a magnitude and a direction. (Section 8.4) The dipole moment of a polyatomic molecule is the vector sum of its bond dipoles. Both the magnitudes *and* the directions of the bond dipoles must be considered when summing vectors. The two bond dipoles in CO_2, although equal in magnitude, are opposite in direction. Adding them is the same as adding two numbers that are equal in magnitude but opposite in sign, such as $100 + (-100)$. The bond dipoles, like the numbers, "cancel" each other. Therefore, the dipole moment of CO_2 is zero, even though the individual bonds are polar. The geometry of the molecule dictates that the overall dipole moment be zero, making CO_2 a *nonpolar* molecule.

Now let's consider H_2O, a bent molecule with two polar bonds [Figure 9.10(**b**)]. Again, the two bonds are identical, and the bond dipoles are equal in magnitude. Because the molecule is bent, however, the bond dipoles do *not* directly oppose each other and therefore do *not* completely cancel. Hence, the H_2O molecule has an overall nonzero dipole moment (measured dipole moment, $\mu = 1.85$ D) and is therefore a *polar* molecule. The oxygen atom carries a partial negative charge, whereas the hydrogen atoms each have a partial positive charge, as shown in Figure 9.10(b).

CO_2 and H_2O are both AB_2 molecules, yet one is nonpolar whereas the other is polar. The shape of CO_2 dictates that the individual bond dipoles *must* cancel completely. We can generalize this observation: For AB_n molecules in which the B atoms are the same, the molecular geometry will determine whether the molecule is polar or nonpolar. Figure 9.11 shows some examples of nonpolar and polar AB_n molecules—whether the bond dipoles completely cancel depends entirely on the molecular geometry. For example, the bond

Go Figure What is the sum of the two red vectors at the top of the left figure?

dipoles of trigonal planar BF_3 cancel completely, whereas in trigonal pyramidal NH_3 the bond dipoles do not completely cancel. **Table 9.4** summarizes the geometries that lead to nonpolar and polar AB_n molecules.

Figure 9.11 also shows the CH_3Cl molecule, which is polar in spite of having a tetrahedral geometry. In this instance, one of the outer atoms is different from the others, so the bond dipoles don't cancel completely. In general, we can use Table 9.4 to determine whether a molecule is nonpolar only if all of the outer atoms are the same.

Sample Exercise 9.4
Polarity of Molecules

Predict whether these molecules are polar or nonpolar: (**a**) BrCl, (**b**) SO_2, (**c**) SF_6.

SOLUTION

Analyze We are given three molecular formulas and asked to predict whether the molecules are polar.

Plan A molecule containing only two atoms is polar if the atoms differ in electronegativity. The polarity of a molecule containing three or more atoms depends on both the molecular geometry and the individual bond polarities. Thus, we must draw a Lewis structure for each molecule containing three or more atoms and determine its molecular geometry. We then use electronegativity values to determine the direction of the bond dipoles. Finally, we see whether the bond dipoles cancel to give a nonpolar molecule or reinforce each other to give a polar one.

Solve

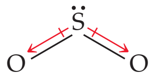
(**a**) Chlorine is more electronegative than bromine. All diatomic molecules with polar bonds are polar molecules. Consequently, BrCl is polar, with chlorine carrying the partial negative charge:

The measured dipole moment μ of BrCl is 0.57 D.

(**b**) Because oxygen is more electronegative than sulfur, SO_2 has polar bonds. Three resonance forms can be written:

$$:\ddot{\underset{\cdot\cdot}{O}}-\ddot{S}=\ddot{O}: \longleftrightarrow :\ddot{O}=\ddot{S}-\ddot{\underset{\cdot\cdot}{O}}: \longleftrightarrow :\ddot{O}=\ddot{S}=\ddot{O}:$$

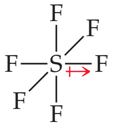
For each of these, the VSEPR model predicts a bent molecular geometry. Because the molecule is bent, the bond dipoles do not cancel, and the molecule is polar:



Experimentally, the dipole moment μ of SO_2 is 1.63 D.

Continued

(**c**) Fluorine is more electronegative than sulfur, so the bond dipoles point toward fluorine. For clarity, only one S—F dipole is shown. The six S—F bonds are arranged octahedrally around the central sulfur:



Because the octahedral molecular geometry is symmetrical, the bond dipoles cancel, and the molecule is nonpolar, meaning that $\mu = 0$.

▶ Practice Exercise

Determine whether the following molecules are polar or nonpolar: (**a**) SF_4, (**b**) $SiCl_4$.

Self-Assessment Exercises

SAE 9.8 Which of the following statements about bond dipoles and the polarity of molecules is *false*? (**a**) An AB_n molecule will have n bond dipoles. (**b**) If all the bond dipoles in a molecule are nonzero, then the molecule must be polar. (**c**) The overall dipole moment of a molecule is the vector sum of its individual bond dipoles. (**d**) Bond dipoles have both a magnitude and a direction. (**e**) The magnitude of a bond dipole depends on the electronegativity difference of the two atoms involved.

SAE 9.9 Which of the following molecules is polar? (**a**) CF_4 (**b**) XeF_4 (**c**) PF_5 (**d**) IF_5

9.4 | Covalent Bonding and Orbital Overlap

Learning Objective

When you finish Section 9.4, you should be able to:

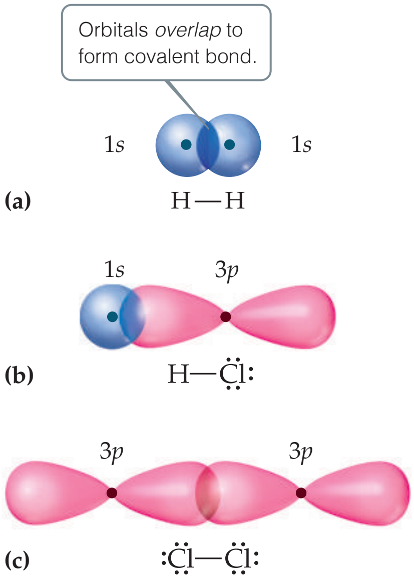
- ▶ Describe the principles of valence-bond theory, in which bonds form between two atoms via the overlap of their atomic orbitals.

The VSEPR model provides a simple means for predicting molecular geometries but does not explain why bonds exist between atoms. In developing theories of covalent bonding, chemists have approached the problem from another direction, using quantum mechanics. How can we use atomic orbitals to explain bonding and to account for molecular geometries? The marriage of Lewis's notion of electron-pair bonds and the idea of atomic orbitals leads to a model of chemical bonding, called **valence-bond theory**, in which bonding electron pairs are concentrated in the regions between atoms, and nonbonding electron pairs lie in directed regions of space away from the bonds. By extending this approach to include the ways in which atomic orbitals can mix with one another, we obtain an explanatory picture that corresponds to the VSEPR model.

In Lewis theory, covalent bonding occurs when atoms share electrons because the sharing concentrates electron density between the nuclei. In valence-bond theory, we visualize the buildup of electron density between two nuclei as occurring when a valence atomic orbital of one atom shares space, or *overlaps*, with a valence atomic orbital of another atom. The overlap of orbitals allows two electrons of opposite spin to share the space between the nuclei, forming a covalent bond.

Figure 9.12 shows three examples of how valence-bond theory describes the coming together of two atoms to form a molecule. In the formation of H_2 [Figure 9.12(a)], each hydrogen atom has a single electron in a 1*s* orbital. As the orbitals overlap, electron density is concentrated between the nuclei. Because the electrons in the overlap region are simultaneously attracted to both nuclei, they hold the atoms together, forming a covalent bond.

The idea of orbital overlap producing a covalent bond applies equally well to other molecules. In HCl, for example, chlorine has the electron configuration $[Ne]3s^23p^5$. All the valence orbitals of chlorine are full except one 3*p* orbital, which contains a single electron. This 3*p* orbital overlaps with the 1*s* orbital of H to form the covalent bond that holds HCl together [Figure 9.12(b)]. Because the other two chlorine 3*p* orbitals are already each filled with a pair of electrons, they do not participate in the bonding to hydrogen. Likewise, we can explain the covalent bond in Cl_2 [Figure 9.12(c)] in terms of the overlap of the singly occupied 3*p* orbital of one Cl atom with the singly occupied 3*p* orbital of another.

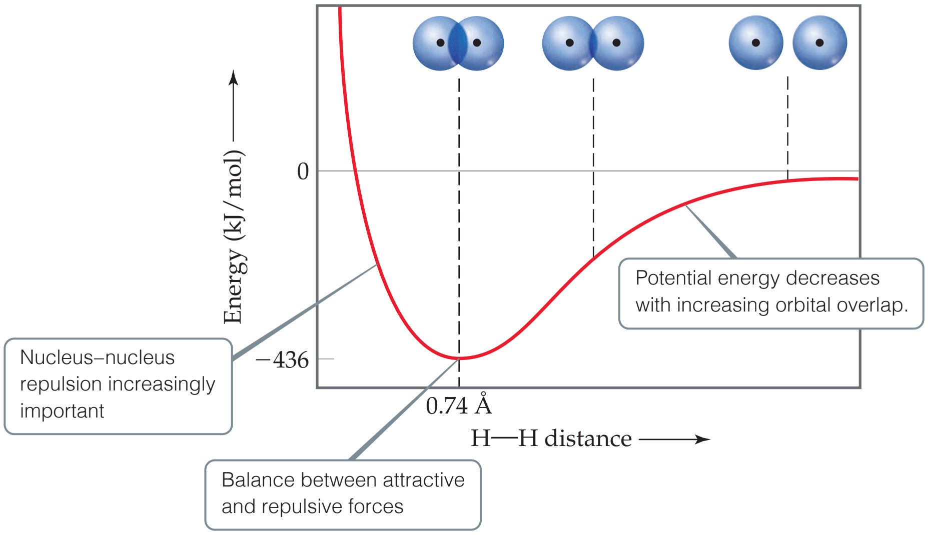


Orbitals *overlap* to form covalent bond.

▲ **Figure 9.12 Covalent bonds in H_2, HCl, and Cl_2 result from overlap of atomic orbitals.**

Go Figure

From this graph, what are the bond length and bond strength in the H_2 molecule?



Potential energy decreases with increasing orbital overlap.

Nucleus–nucleus repulsion increasingly important

Balance between attractive and repulsive forces

▲ **Figure 9.13** **Formation of the H_2 molecule as atomic orbitals overlap.** The red curve shows the potential energy of the molecule as a function of H—H distance. The minimum in the curve corresponds to the bond length of the molecule, and the energy at the minimum corresponds to the bond strength of the molecule.

There is always an optimum distance between the two nuclei in any covalent bond. **Figure 9.13** shows how the potential energy of a system consisting of two H atoms changes as the atoms come together to form an H_2 molecule. When the atoms are infinitely far apart, they do not "feel" each other and so the energy approaches zero. As the distance between the atoms decreases, the overlap between their 1*s* orbitals increases. Because of the stabilizing effect of increasing the electron density between the nuclei, the potential energy of the system decreases. That is, the strength of the bond increases, as shown by the decrease in the potential energy of the two-atom system. However, Figure 9.13 also shows that the energy increases sharply when the distance between the two hydrogen nuclei is less than 0.74 Å. The increase in potential energy of the system, which becomes significant at short internuclear distances, is due mainly to the electrostatic repulsion between the positively charged nuclei. The internuclear distance at the minimum of the potential-energy curve (in this example, at 0.74 Å) corresponds to the bond *length* of the molecule. The potential energy at this minimum corresponds to the bond *strength*. Thus, the observed bond length is the distance at which the sum of the attractive forces between unlike charges (electrons and nuclei) and the repulsive forces between like charges (electron–electron and nucleus–nucleus) is most negative.

Valence-bond theory explains the energetic reasons that bonds form via the overlap of orbitals on different atoms. In order to connect the theory more directly to the molecular geometries we obtain from the VSEPR model, we need to develop one more concept—how atomic orbitals can mix in a certain way to explain the electron-domain geometries that are so key to using VSEPR. We address this issue in the next section.

Self-Assessment Exercise

SAE 9.10 Which of the following statements about orbital overlap and covalent bonding is *false*? (**a**) In valence-bond theory, bonds are formed by the overlap of atomic orbitals on different atoms. (**b**) *p* orbitals can overlap only with other *p* orbitals. (**c**) As two atoms are pulled apart, the overlap between their atomic orbitals decreases. (**d**) The energy required to separate the atoms in an H_2 molecule reaches its maximum value at the observed bond length of 0.74 Å.

9.5 | Hybrid Orbitals

Learning Objectives

When you finish Section 9.5, you should be able to:

- Contrast atomic orbitals and hybrid orbitals.
- Demonstrate the formation of *sp* hybrid orbitals from an *s* and a *p* orbital on the same atom.
- Illustrate the formation and spatial orientation of sp^2 and sp^3 hybrid orbitals.

The VSEPR model, simple as it is, does a surprisingly good job at predicting molecular shape, despite the fact that it has no obvious relationship to the filling and shapes of atomic orbitals. For example, we would like to understand how to account for the tetrahedral arrangement of C—H bonds in methane in terms of the 2*s* and 2*p* orbitals of the central carbon atom, which are not directed toward the apices of a tetrahedron. How can we reconcile the notion that covalent bonds are formed from the overlap of atomic orbitals with the molecular geometries that come from the VSEPR model?

To begin with, recall that atomic orbitals are mathematical functions that come from the quantum-mechanical model for atomic structure. (Section 6.5) To explain molecular geometries, we often assume that the atomic orbitals on an atom (usually the central atom) mix to form new orbitals called **hybrid orbitals**. The shape of any hybrid orbital is different from the shapes of the original atomic orbitals. The process of mixing atomic orbitals is a mathematical operation called **hybridization**. The total number of atomic orbitals on an atom remains constant, so the number of hybrid orbitals on an atom equals the number of atomic orbitals that are mixed.

As we examine the common types of hybridization, notice the connection between the type of hybridization and some of the molecular geometries predicted by the VSEPR model: linear, bent, trigonal planar, and tetrahedral.

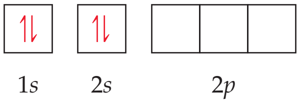
sp Hybrid Orbitals

To illustrate the process of hybridization, consider the BeF_2 molecule, which has the Lewis structure

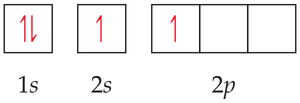
$$:\underset{..}{\overset{..}{F}}-Be-\underset{..}{\overset{..}{F}}:$$

The VSEPR model predicts that BeF_2 is linear with two identical Be—F bonds, in accord with experiment. How can we use valence-bond theory to describe the bonding? The electron configuration of F ($1s^22s^22p^5$) indicates an unpaired electron in a 2*p* orbital. This electron can be paired with an unpaired Be electron to form a polar covalent bond. Which orbitals on the Be atom, however, overlap with those on the F atoms to form the Be—F bonds?

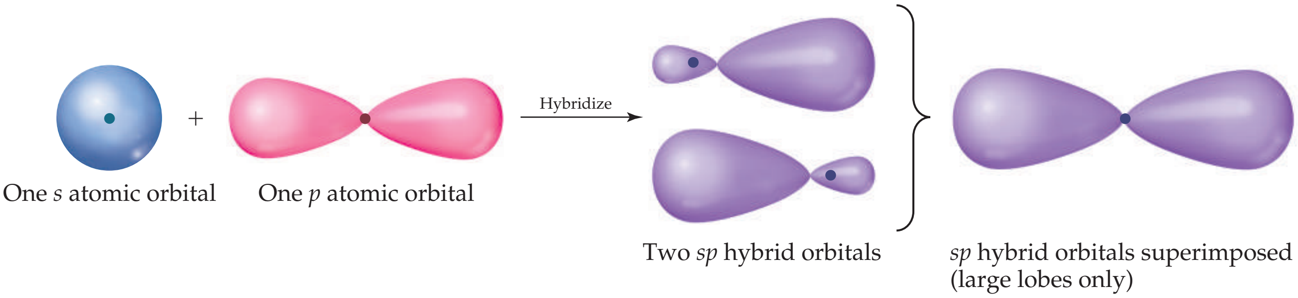
The orbital diagram for a ground-state Be atom is



Because it has no unpaired electrons, the Be atom in its ground state cannot bond with the fluorine atoms. The Be atom could form two bonds, however, by envisioning that we “promote” one of the 2*s* electrons to a 2*p* orbital:



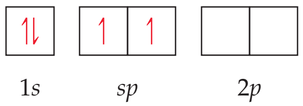
Promoting an electron requires energy. However, the Be atom now has two unpaired electrons and can therefore form two polar covalent bonds with F atoms, which would release more energy than was expended in promotion. The two bonds would not be identical, however, because a Be 2*s* orbital would be used to form one of the bonds and a 2*p* orbital would be used to form the other. Therefore, although the promotion of an electron allows two Be—F bonds to form, we still have not explained the structure of BeF_2.



▲ **Figure 9.14** **Formation of *sp* hybrid orbitals.**

We can solve this dilemma by “mixing” the 2*s* orbital with one 2*p* orbital to generate two new orbitals, as shown in **Figure 9.14**.* Like *p* orbitals, each new orbital has two lobes. Unlike *p* orbitals, however, one lobe is much larger than the other. The two new orbitals are identical in shape, but their large lobes point in opposite directions. These two new orbitals, which are shown in purple in Figure 9.14, are hybrid orbitals. Because we have hybridized one *s* and one *p* orbital, we call each hybrid an *sp* hybrid orbital. *According to the valence-bond model, a linear arrangement of electron domains implies* sp *hybridization.*

For the Be atom of BeF_2, we write the orbital diagram for the formation of two *sp* hybrid orbitals as



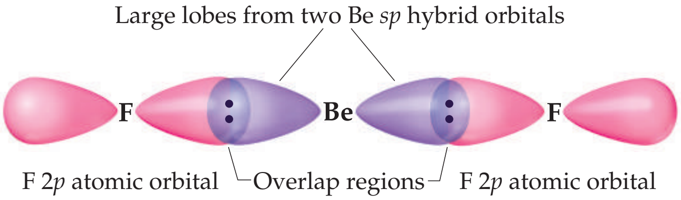
The electrons in the *sp* hybrid orbitals can form bonds with the two fluorine atoms (**Figure 9.15**). Because the *sp* hybrid orbitals are equivalent but point in opposite directions, BeF_2 has two identical bonds and a linear geometry. Furthermore, the large lobes of the hybrid orbitals allow them to overlap very effectively with the orbitals of other atoms.

We have used one of the three Be 2*p* orbitals in making the two *sp* hybrids; the remaining two 2*p* atomic orbitals of Be remain unhybridized and are vacant. Remember also that each fluorine atom has two other valence 2*p* atomic orbitals, each containing one nonbonding electron pair. Those atomic orbitals are omitted from Figure 9.15 to simplify the illustration.

sp^2 and *sp*^{3} Hybrid Orbitals

Whenever we mix a certain number of atomic orbitals, we get the same number of hybrid orbitals. Each hybrid orbital is equivalent to the others but points in a different direction. Thus, mixing one 2*s* and one 2*p* atomic orbital yields two equivalent *sp* hybrid orbitals that point in opposite directions (Figure 9.14). Other combinations of atomic orbitals can be hybridized to obtain different geometries, such as sp^2 and sp^3.

In BF_3, for example, mixing the 2*s* and two of the 2*p* atomic orbitals yields three equivalent sp^2 (pronounced “*s*-*p*-two”) hybrid orbitals (**Figure 9.16**). The three sp^2 hybrid orbitals lie in the same plane, 120° apart from one another. They are used to make three equivalent bonds with the three fluorine atoms, leading to the trigonal-planar molecular geometry of BF_3. Notice that an unfilled 2*p* atomic orbital remains unhybridized; it is oriented perpendicular to the plane defined by the three sp^2 hybrid orbitals, with one lobe



◀ **Figure 9.15** **Formation of two equivalent Be—F bonds in BeF_2.**

---

*By mixing, we mean mathematically taking two linear combinations of the 2*s* and 2*p* atomic orbital wave functions. We do not discuss the mathematical details of hybridization because they are beyond the scope of an introductory textbook.

Go Figure What is the angle formed between the large lobes of the three sp^2 hybrid orbitals?

▲ **Figure 9.16 Formation of sp^2 hybrid orbitals.**

above and one below the plane. This unhybridized orbital becomes important when we discuss double bonds in Section 9.6.

An *s* atomic orbital can mix with all three *p* atomic orbitals in the same subshell. For example, the carbon atom in CH_4 forms four equivalent bonds with the four hydrogen atoms. We envision this process as resulting from the mixing of the 2*s* and all three 2*p* atomic orbitals of carbon to create four equivalent sp^3 (pronounced "*s*-*p*-three") hybrid orbitals. Each sp^3 hybrid orbital has a large lobe that points toward one vertex of a tetrahedron (**Figure 9.17**). These hybrid orbitals can be used to form two-electron bonds by overlap with the atomic orbitals of another atom, such as H. Using valence-bond theory, we can describe the bonding in CH_4 as the overlap of four equivalent sp^3 hybrid orbitals on C with the 1*s* orbitals of the four H atoms to form four equivalent bonds.

The idea of hybridization is also used to describe the bonding in molecules containing nonbonding pairs of electrons. In H_2O, for example, the O atom has four electron domains about it—two bonding domains and two nonbonding domains. From VSEPR, we therefore expect a tetrahedral electron-domain geometry around the O atom, which we can explain using sp^3 hybridization (**Figure 9.18**). Two of the hybrid orbitals contain nonbonding pairs of electrons, and the other two form valence bonds via overlap with the H 1*s* orbitals.

Hypervalent Molecules

So far our discussion of hybridization has extended only to period 2 elements—specifically carbon, nitrogen, and oxygen. The elements of period 3 and beyond introduce a new consideration because in many of their compounds these elements are **hypervalent**—they have more than an octet of electrons around the central atom. (Section 8.7) We saw in Section 9.2 that the VSEPR model works well to predict the geometries of hypervalent molecules such as PCl_5, SF_6, or BrF_5. But can we extend the use of hybrid orbitals to describe the bonding in these molecules? In short, the answer is no; hybrid orbitals should not be used for hypervalent molecules. Let's examine the reasons.

The valence-bond model we developed for period 2 elements works well for compounds of period 3 elements as long as we have no more than an octet of electrons in the valence-shell orbitals. Thus, for example, it is appropriate to discuss the bonding in PF_3 or H_2Se in terms of hybridized *s* and *p* orbitals on the central atom.

For compounds with more than an octet, we could imagine increasing the number of hybrid orbitals formed by including valence-shell *d* orbitals. For example, for SF_6 we could

envision mixing in two sulfur 3*d* orbitals in addition to the 3*s* and three 3*p* orbitals to make a total of six hybrid orbitals. However, the sulfur 3*d* orbitals are substantially higher in energy than the 3*s* and 3*p* orbitals, so the amount of energy needed to form the six hybrid orbitals is greater than the amount returned by forming bonds with the six

fluorine atoms. Theoretical calculations suggest that the sulfur 3*d* orbitals do *not* participate to a significant degree in the bonding between sulfur and the six fluorine atoms, and that it would not be valid to describe the bonding in SF_6 in terms of six hybrid orbitals. The more detailed bonding model needed to discuss the bonding in SF_6 and other hypervalent molecules requires a treatment beyond the scope of a general chemistry text. Fortunately, the VSEPR model, which explains the geometrical properties of such molecules in terms of electrostatic repulsions, does a good job of predicting their geometries.

This discussion reminds us that models in science are not reality but rather they are our attempts to describe aspects of reality that we have been able to measure, such as bond distances, bond energies, molecular geometries, and so on. A model may work well up to a certain point but not beyond it, as is the case for hybrid orbitals. The hybrid orbital model for period 2 elements has proven very useful and is an essential part of any modern discussion of bonding and molecular geometry in organic chemistry. When it comes to molecules such as SF_6, however, we encounter the limitations of the model.

Hybrid Orbital Summary

Overall, hybrid orbitals provide a convenient model for using valence-bond theory to describe covalent bonds in molecules that have an octet or less of electrons around the central atom and in which the molecular geometry conforms to the electron-domain geometry predicted by the VSEPR model. While the concept of hybrid orbitals has limited predictive value, *when we know the electron-domain geometry, we can employ hybridization to describe the atomic orbitals used by the central atom in bonding*.

How to Describe the Hybrid Orbitals Used by an Atom in Bonding

1. Draw the *Lewis structure* for the molecule or ion.
2. Use the VSEPR model to determine the electron-domain geometry around the central atom.
3. Specify the *hybrid orbitals* needed to accommodate the electron pairs based on their geometric arrangement (**Table 9.5**).

These steps are illustrated in **Figure 9.19**, which shows how the hybridization at N in NH_3 is determined.

TABLE 9.5 Geometric Arrangements Characteristic of Hybrid Orbital Sets

Sample Exercise 9.5

Describing the Hybridization of a Central Atom

Describe the orbital hybridization around the central atom in NH_2^-.

SOLUTION

Analyze We are given the chemical formula for a polyatomic anion and asked to describe the type of hybrid orbitals surrounding the central atom.

Plan To determine the central atom hybrid orbitals, we must know the electron-domain geometry around the atom. Thus, we draw the Lewis structure to determine the number of electron domains around the central atom. The hybridization conforms to the number and geometry of electron domains around the central atom as predicted by the VSEPR model.

Solve The Lewis structure is

$$\left[\mathrm{H}:\underset{\cdot\cdot}{\ddot{\mathrm{N}}}:\mathrm{H}\right]^-$$

Because there are four electron domains around N, the electron-domain geometry is tetrahedral. The hybridization that gives a tetrahedral electron-domain geometry is sp^3 (Table 9.5). Two of the sp^3 hybrid orbitals contain nonbonding pairs of electrons, and the other two are used to make bonds with the hydrogen atoms.

▶ **Practice Exercise**

Predict the electron-domain geometry and hybridization of the central atom in SO_3^{2-}.

Self-Assessment Exercises

SAE 9.11 Which of the following statements about the formation of hybrid orbitals is *false*? (**a**) Hybrid orbitals are a means to explain the formation of bonds consistent with the molecular shapes predicted by the VSEPR model. (**b**) The shapes of hybrid orbitals are different from the shapes of atomic orbitals. (**c**) Hybrid orbitals are created by mixing an orbital on one atom with an orbital on a different atom. (**d**) The formation of hybrid orbitals may require the promotion of an electron from an *s* orbital to a *p* orbital.

SAE 9.12 Fill in the blanks in the following statement: The formation of *sp* hybrid orbitals involves the mixing of an *s* orbital with ____ *p* orbital(s) to create ____ hybrids. The angle between the large lobes of the hybrids is ____ degrees. (**a**) one, two, 180 (**b**) one, two, 90 (**c**) two, three, 180 (**d**) two, three, 120 (**e**) three, four, 109.5

SAE 9.13 Which of the following statements about hybridization is or are *true*?

- (**i**) When an atom undergoes *sp* hybridization, there is one unhybridized *p* orbital remaining on the atom.
- (**ii**) Under sp^2 hybridization, the large lobes point to the vertices of an equilateral triangle.
- (**iii**) The angle between the large lobes of sp^3 hybrids is 109.5°.

(**a**) Only one of the statements is true. (**b**) Statements i and ii are true. (**c**) Statements i and iii are true. (**d**) Statements ii and iii are true. (**e**) All three statements are true.

SAE 9.14 How many of the following AB_n molecules and ions exhibit sp^3 hybridization at the central atom: H_2O, CH_3^+, BF_3, PCl_3, NO_3^-? (**a**) 0 (**b**) 1 (**c**) 2 (**d**) 3 (**e**) 4

9.6 | Multiple Bonds

Learning Objectives

When you finish Section 9.6, you should be able to:

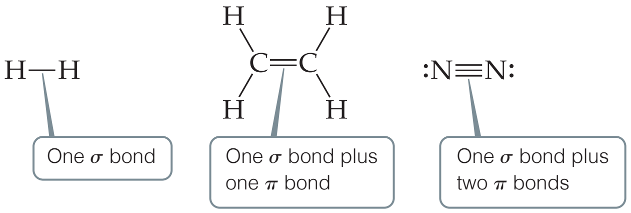
- Define and contrast σ (sigma) and π (pi) bonds.
- For each σ and π bond in a molecule, identify the hybridized and/or unhybridized atomic orbitals from which it is formed.
- Determine whether a molecule or ion exhibits delocalized π bonding and, if so, how many electrons are in the π system.

In the covalent bonds we have considered thus far, the electron density is concentrated along the line connecting the nuclei (the *internuclear axis*). The line joining the two nuclei passes through the middle of the overlap region, forming a type of covalent bond called a **sigma (σ) bond**. Examples of sigma bond formation include:

- the overlap of two *s* orbitals; one from each H in H_2 [Figure 9.12(a)],
- the overlap of an H *s* orbital and a Cl *p* orbital in HCl [Figure 9.12(b)],
- the overlap of two *p* orbitals; one from each Cl in Cl_2 [Figure 9.12(c)],
- the overlap of an F *p* orbital and a Be *sp* hybrid orbital in BeF_2 (Figure 9.15),
- the overlap of a H *s* orbital and a N sp^3 hybrid orbital in NH_3 (Figure 9.19).

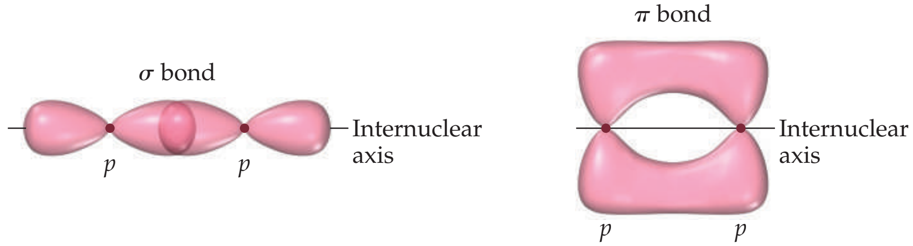
To describe multiple bonding, we must consider a second kind of bond—one that results from the overlap between two *p* orbitals oriented perpendicularly to the internuclear axis (**Figure 9.20**). The sideways overlap of *p* orbitals produces what is called a **pi (π) bond**. A π bond is one in which the overlap regions lie above and below the internuclear axis. Unlike a σ bond, the electron density in a π bond is not concentrated on the internuclear axis. Because the two *p* orbitals that overlap sideways in a π bond are not pointed directly at one another, they do not overlap as strongly as do the *p* orbitals in a σ bond. As a result, π bonds are generally weaker than σ bonds.

In almost all cases, single bonds are σ bonds. A double bond consists of one σ bond and one π bond, and a triple bond consists of one σ bond and two π bonds:

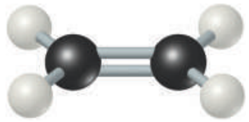


Ethylene (C_2H_4), for example, has a C=C double bond (**Figure 9.21**). The three bond angles about each carbon are all nearly 120°, suggesting that each carbon atom uses sp^2 hybrid orbitals (Figure 9.16) to form σ bonds with the other carbon and with two hydrogens. Each carbon atom also has an *unhybridized* 2*p* orbital, which is directed perpendicular to the plane that contains the three sp^2 hybrid orbitals. Let's analyze more closely how the orbitals involved can be used to build the bonds of the ethylene molecule.

Go Figure How many bonds are represented in each of the two parts of the figure?



▲ **Figure 9.20 Comparison of σ and π bonds.** Note that the *two* regions of overlap in the π bond—one above and one below the internuclear axis—constitute a single π bond.

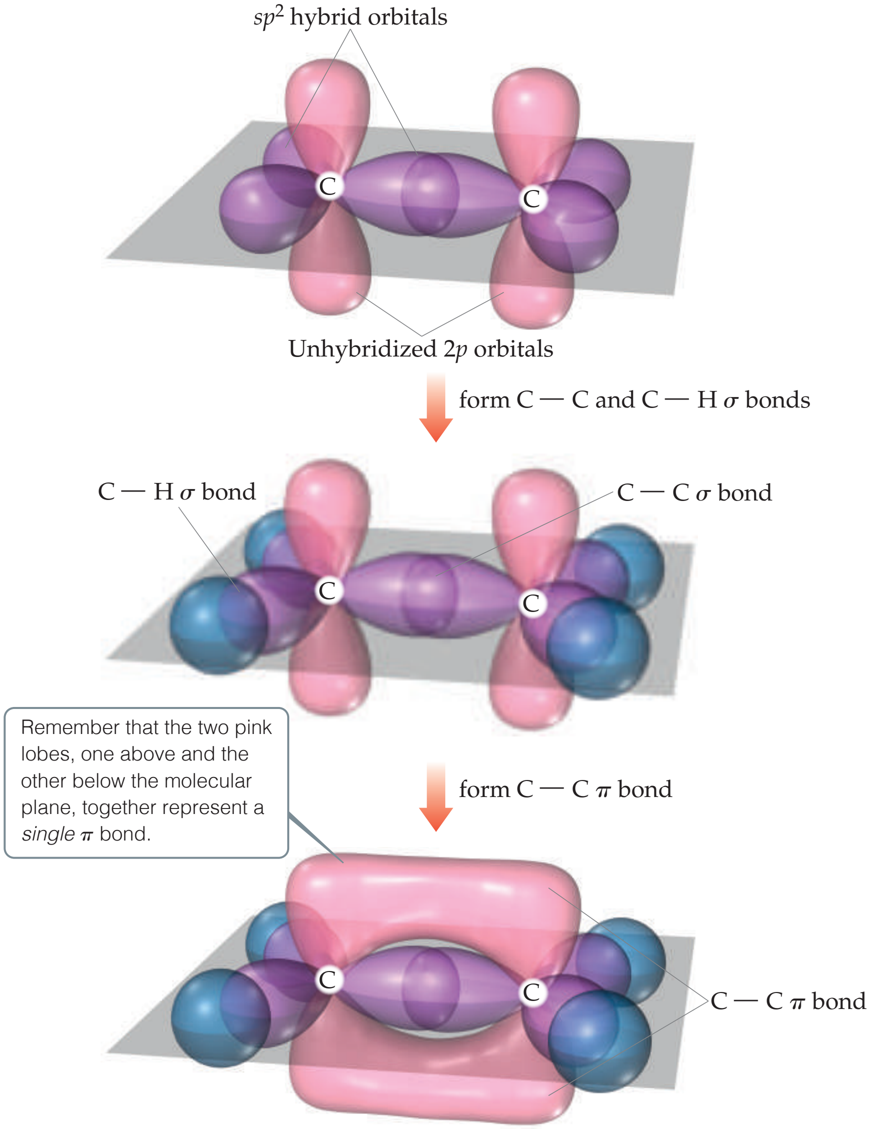


▲ **Figure 9.21 Trigonal-planar molecular geometry of ethylene.** The double bond is made up of one C—C σ bond and one C—C π bond.

Figure 9.22 shows how we can first envision forming the C—C σ bond in ethylene by the overlap of two sp^2 hybrid orbitals, one on each carbon atom. Two electrons are used in forming the C—C σ bond. Next, the C—H σ bonds are formed by overlap of the remaining sp^2 hybrid orbitals on the C atoms with the 1*s* orbitals on each H atom. We use eight more electrons to form these four C—H bonds. Thus, 10 of the 12 valence electrons in the C_2H_4 molecule are used to form five σ bonds.

Go Figure

Why is it important that the sp^2 hybrid orbitals of the two carbon atoms lie in the same plane?



Remember that the two pink lobes, one above and the other below the molecular plane, together represent a *single* π bond.

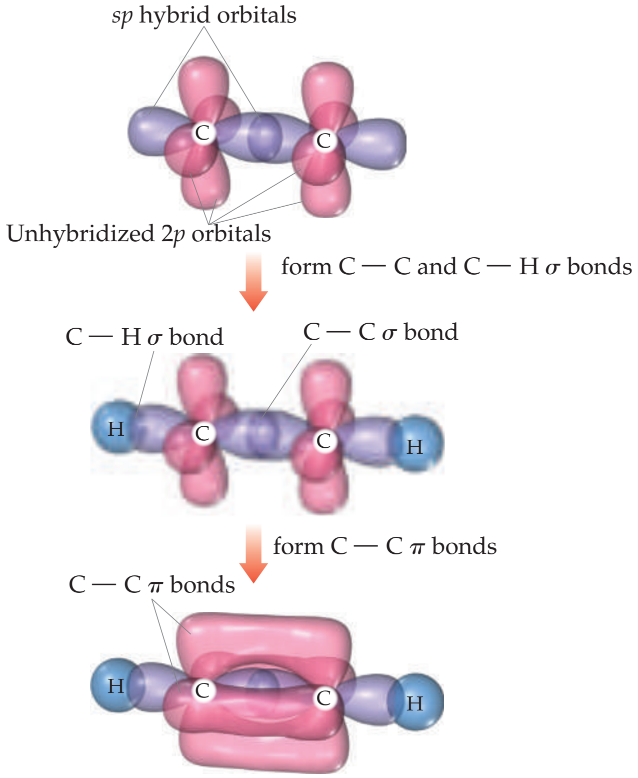
▲ **Figure 9.22 Hybrid orbital bonding in ethylene.**

The remaining two valence electrons reside in the unhybridized $2p$ orbitals, one electron on each carbon. These two orbitals can overlap sideways with each other to form a π bond, as shown in Figure 9.22. Thus, the C═C double bond in ethylene consists of one σ bond and one π bond.

Although we cannot experimentally observe a π bond directly (all we can observe are the positions of the atoms), the structure of ethylene provides strong support for its presence. First, the C—C bond length in ethylene (1.34 Å) is much shorter than in compounds with C—C single bonds (1.54 Å), consistent with the presence of a stronger C═C double bond. (Section 8.8) Second, all six atoms in C_2H_4 lie in the same plane. The p orbitals on each C atom that make up the π bond can achieve a good overlap only when the two CH_2 fragments lie in the same plane. Because π bonds require that portions of a molecule be planar, they can introduce rigidity into molecules.

Triple bonds can also be explained using hybrid orbitals. Acetylene (C_2H_2), for example, is a linear molecule containing a triple bond: H—C≡C—H. The linear geometry suggests that each carbon atom uses sp hybrid orbitals to form σ bonds with the other carbon and one hydrogen. Because only one p orbital is used in making sp hybrids on an atom,

Go Figure Based on the models of bonding in ethylene and acetylene, which molecule should have the greater carbon–carbon bond strength?



▲ **Figure 9.23** **Formation of two π bonds in acetylene, C_2H_2.**

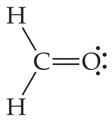
each carbon atom has two unhybridized 2*p* orbitals at right angles to each other and to the axis of the *sp* hybrid set (**Figure 9.23**). These unhybridized *p* orbitals overlap to form a pair of π bonds. The triple bond in acetylene therefore consists of one σ bond and two π bonds.

Although it is possible to make π bonds from *d* orbitals, the only π bonds that we consider in this chapter are those formed by the overlap of *p* orbitals. These π bonds can form only if unhybridized *p* orbitals are present on the bonded atoms. Therefore, only atoms having *sp* or sp^2 hybridization can form π bonds. Further, double and triple bonds (and hence π bonds) are more common in molecules made up of period 2 atoms, especially C, N, and O. Larger atoms, such as S, P, and Si, form π bonds less readily.

Sample Exercise 9.6

Describing σ and π Bonds in a Molecule

Formaldehyde, H_2CO, has the Lewis structure



Describe how the bonds in formaldehyde are formed in terms of overlaps of hybrid and unhybridized orbitals.

SOLUTION

Analyze We are asked to describe the bonding in formaldehyde in terms of hybrid orbitals.

Plan Single bonds are σ bonds, whereas double bonds consist of one σ bond and one π bond. The ways in which these bonds form can be deduced from the molecular geometry, which we predict using the VSEPR model.

Solve The C atom has three electron domains around it, which suggests a trigonal-planar geometry with bond angles of about 120°. This geometry implies sp^2 hybrid orbitals on C (Table 9.5). These hybrids are used to make the two C—H and one C—O σ bonds to C. There remains an unhybridized 2*p* orbital on carbon, perpendicular to the plane of the three sp^2 hybrids.

The O atom also has three electron domains around it, and so we assume it has sp^2 hybridization as well. One of these hybrid orbitals participates in the C—O σ bond, while the other two hold the two nonbonding electron pairs of the O atom. Like the C atom, therefore, the O atom has a p orbital that is perpendicular to the plane of the molecule. The two p orbitals overlap to form a C—O π bond (**Figure 9.24**).

$$H-\overset{\displaystyle H}{\underset{\displaystyle H}{\overset{|}{\underset{|}{C}}}}-C\equiv N\!:$$

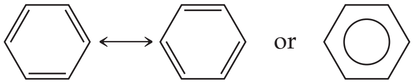
(**b**) Describe the hybridization at each carbon atom.

(**c**) Determine the number of σ and π bonds in the molecule.

Resonance Structures, Delocalization, and π Bonding

In the molecules we have discussed thus far in this section, the bonding electrons are *localized*. By this we mean that the σ and π electrons are associated totally with the two atoms that form the bond. In many molecules, however, we cannot adequately describe the bonding as being entirely localized. This situation arises particularly in molecules that have two or more resonance structures involving π bonds.

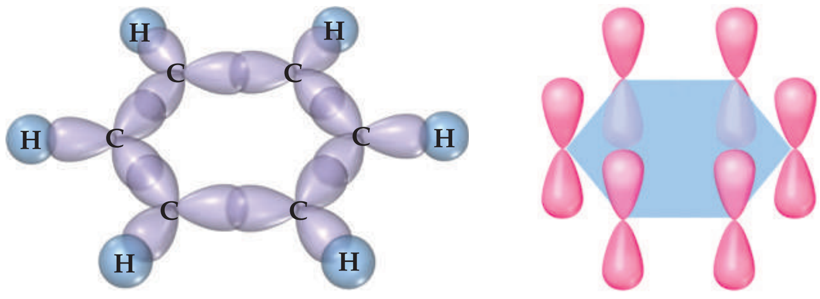
One molecule that cannot be described with localized π bonds is benzene (C_6H_6), which has two resonance structures: (Section 8.6)



Benzene has a total of 30 valence electrons. To describe the bonding in benzene using hybrid orbitals, we first choose a hybridization scheme consistent with the geometry of the molecule. Because each carbon is surrounded by three atoms at 120° angles, the appropriate hybrid set is sp^2. Six localized C—C σ bonds and six localized C—H σ bonds are formed from the sp^2 hybrid orbitals, as shown in **Figure 9.25**(**a**). Thus, 24 of the valence electrons are used to form the σ bonds in the molecule.

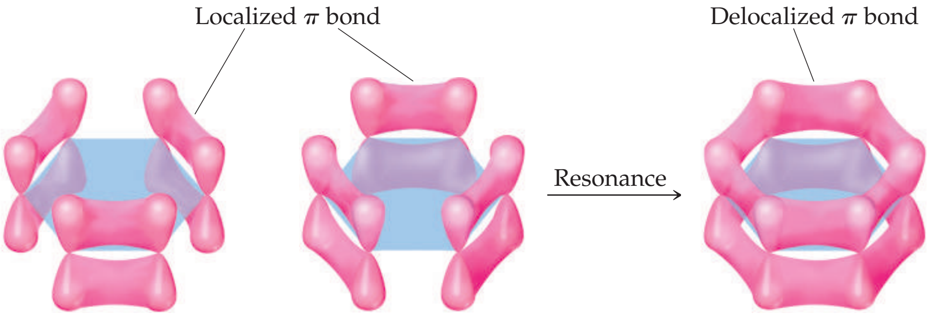
Because the hybridization at each C atom is sp^2, there is one p orbital on each C atom, each oriented perpendicular to the plane of the molecule. The situation is very much like that in ethylene except we now have six p orbitals arranged in a ring [**Figure 9.25**(**b**)]. The remaining six valence electrons occupy these six p orbitals, one per orbital.

Go Figure What are the two kinds of σ bonds found in benzene?



(**a**) σ bonds (**b**) p orbitals

▲ **Figure 9.25 σ and π bond networks in benzene, C_6H_6.** (**a**) The σ bond framework. (**b**) The π bonds are formed from overlap of the unhybridized 2p orbitals on the six carbon atoms.



▲ **Figure 9.26** **Delocalized π bonds in benzene.**

We could envision using the *p* orbitals to form three localized π bonds. As shown in **Figure 9.26**, there are two equivalent ways to make these localized bonds, each corresponding to one resonance structure. However, a representation that reflects *both* resonance structures has the six π electrons "smeared out" among all six carbon atoms, as shown on the right in Figure 9.26. Notice how this smeared representation corresponds to the circle-in-a-hexagon drawing we often use to represent benzene. This model leads us to predict that all the carbon–carbon bond lengths will be identical, with a bond length between that of a C—C single bond (1.54 Å) and that of a C=C double bond (1.34 Å). This prediction is consistent with the observed carbon–carbon bond length in benzene (1.40 Å).

Because we cannot describe the π bonds in benzene as individual bonds between neighboring atoms, we say that benzene has a six-electron π system **delocalized** among the six carbon atoms. Delocalization of the electrons in its π bonds gives benzene a special stability. Electron delocalization in π bonds is also responsible for the color of many organic molecules. A final important point to remember about delocalized π bonds is the constraint they place on the geometry of a molecule. For optimal overlap of the *p* orbitals, all the atoms involved in a delocalized π bonding network should lie in the same plane. This restriction imparts a certain rigidity to the molecule that is absent in molecules containing only σ bonds (see the box "Chemistry and Life: The Chemistry of Vision").

If you take a course in organic chemistry, you will see many examples of how electron delocalization influences the properties of organic molecules.

Sample Exercise 9.7

Delocalized Bonding

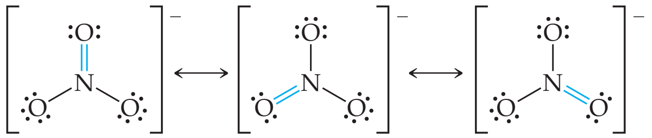
Describe the bonding in the nitrate ion, NO_3^-. Does this ion have delocalized π bonds?

SOLUTION

Analyze Given the chemical formula for a polyatomic anion, we are asked to describe the bonding and determine whether the ion has delocalized π bonds.

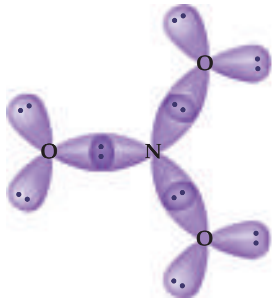
Plan Our first step is to draw Lewis structures. Multiple resonance structures involving the placement of the double bonds in different locations would suggest that the π component of the double bonds is delocalized.

Solve In Section 8.6 we saw that NO_3^- has three resonance structures:



As we have discussed previously, the three N—O bonds in the ion are equivalent and are between a normal N—O single bond and a N=O double bond in length. (Section 8.6) In each resonance structure, the electron-domain geometry at nitrogen is trigonal planar, which implies sp^2 hybridization of the N atom. It is helpful when considering delocalized π bonding to consider atoms with lone pairs that are bonded to the central atom to be sp^2 hybridized as well. Thus, we can envision that each of the O atoms in the anion has three sp^2 hybrid orbitals in the plane of the ion. Each of the four atoms has an unhybridized *p* orbital oriented perpendicular to the plane of the ion.

The NO_3^- ion has 24 valence electrons. We can first use the sp^2 hybrid orbitals on the four atoms to construct the three N—O σ bonds. That uses all of the sp^2 hybrids on the N atom and one sp^2 hybrid on each O atom. Each of the two remaining sp^2 hybrids on each O atom is used to hold a nonbonding pair of electrons. Thus, for any of the resonance structures, we have the following arrangement in the plane of the ion:



We have accounted for a total of 18 electrons—6 in the three N—O σ bonds, and 12 as nonbonding pairs on the O atoms. The remaining six electrons will reside in the π system of the ion.

The four *p* orbitals—one on each of the four atoms—are used to build the π system. For any one of the three resonance structures shown, we might imagine a single localized N—O π bond formed by the overlap of the *p* orbital on N and a *p* orbital on one of the O atoms. The remaining two O atoms have nonbonding pairs in their *p* orbitals. Thus, for each of the resonance structures, we have the situation shown in **Figure 9.27**. Because each resonance structure contributes equally to the observed structure of NO_3^-, however, we represent the π bonding as delocalized over the three N—O bonds, as shown in the figure. Thus, the NO_3^- ion has a *six-electron π system delocalized among the four atoms in the ion*.

General Conclusions about σ and π Bonding

On the basis of the examples we have seen, we can draw a few helpful conclusions for using hybrid orbitals to describe molecular structures:

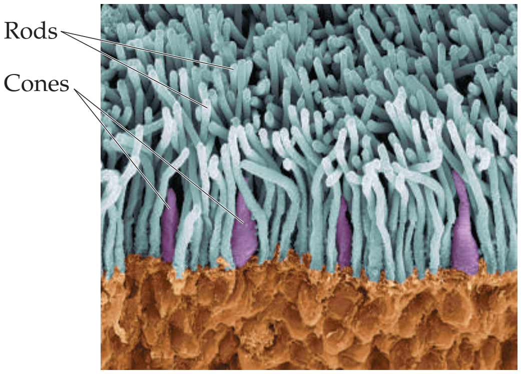
- Every pair of bonded atoms shares one or more pairs of electrons. Each bond line we draw in a Lewis structure represents two shared electrons. In every σ bond, one pair of electrons is localized in the space between the atoms. The appropriate set of hybrid orbitals used to form the σ bonds between an atom and its neighbors is determined by the observed geometry of the molecule. The correlation between the set of hybrid orbitals and the geometry about an atom is given in Table 9.5.
- Because the electrons in σ bonds are localized in the region between two bonded atoms, they do not make a significant contribution to the bonding between any other two atoms.
- When atoms share more than one pair of electrons, one pair is used to form a σ bond; the additional pairs form π bonds. The centers of charge density in a π bond lie above and below the internuclear axis.
- Molecules can have π systems that extend over more than two bonded atoms. Electrons in extended π systems are said to be "delocalized." We can determine the number of electrons in the π system of a molecule using the procedures we discussed in this section.

CHEMISTRY AND LIFE The Chemistry of Vision

Vision begins when light is focused by the lens of the eye onto the retina, the layer of cells lining the interior of the eyeball. The retina contains *photoreceptor* cells called rods and cones (**Figure 9.28**). The rods are sensitive to dim light and are used in night vision. The cones are sensitive to colors. The tops of the rods and cones contain a molecule called *rhodopsin,* which consists of a protein, *opsin,* bonded to a reddish purple pigment called *retinal*. Structural changes around a double bond in the retinal portion of the molecule trigger a series of chemical reactions that result in vision.

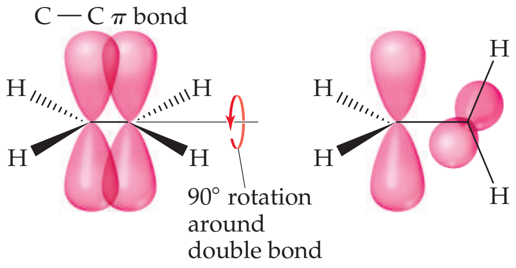
We know that a double bond between two atoms is stronger than a single bond between those same two atoms (Table 8.3). We are now in a position to appreciate another aspect of double bonds: They introduce rigidity into molecules.

Consider the C—C double bond in ethylene. Imagine rotating one —CH_2 group in ethylene relative to the other —CH_2 group, as



▲ **Figure 9.28 Inside the eye.** A color-enhanced scanning electron micrograph of the rods and cones in the retina of the human eye.

Continued



▲ **Figure 9.29 Rotation about the carbon—carbon double bond in ethylene breaks the π bond.**

pictured in **Figure 9.29**. This rotation destroys the overlap of the *p* orbitals, breaking the π bond, a process that requires considerable energy. Thus, the presence of a double bond restricts bond rotation in a molecule. In contrast, molecules can rotate almost freely around the bond axis in single (σ) bonds because this motion has no effect on the orbital overlap for a σ bond. Rotation allows molecules with single bonds to twist and fold almost as if their atoms were attached by hinges.

Our vision depends on the rigidity of double bonds in retinal. In its normal form, retinal is held rigid by its double bonds. Light entering the eye is absorbed by the retinal portion of rhodopsin, and the energy of that light is used to break the π-bond portion of the double bond shown in red in **Figure 9.30**. Breaking the double bond allows rotation around the bond axis, changing the geometry of the retinal molecule. The retinal then separates from the opsin, triggering the reactions that produce a nerve impulse that the brain interprets as the sensation of vision. It takes as few as five closely spaced molecules reacting in this fashion to produce the sensation of vision. Thus, only five photons of light are necessary to stimulate the eye.

The retinal slowly reverts to its original form and reattaches to the opsin. The slowness of this process helps explain why intense bright light causes temporary blindness. The light causes all the retinal to separate from opsin, leaving no molecules to absorb light.

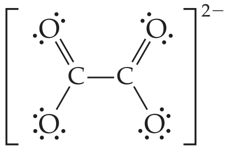
(**c**) The experimentally observed structure of the ion will show two short and two long C—O bonds. (**d**) The π system of the ion is delocalized among all six atoms.



9.7 | Molecular Orbitals

While valence-bond theory helps explain some of the relationships among Lewis structures, atomic orbitals, and molecular geometries, it does not explain all aspects of bonding. It is not successful, for example, in describing the excited states of molecules, which we must understand to explain how molecules absorb light, giving them color.

Some aspects of bonding are better explained by a more sophisticated model called **molecular-orbital theory**. In Chapter 6 we saw that electrons in atoms can be described by wave functions, which we call atomic orbitals. In a similar way, molecular-orbital theory describes the electrons in molecules by using specific wave functions, each of which is called a **molecular orbital (MO)**.

Molecular orbitals have many of the same characteristics as atomic orbitals. For example, an MO can hold a maximum of two electrons (with opposite spins), it has a definite energy, and we can visualize its electron-density distribution by using a contour representation, as we did with atomic orbitals. Unlike atomic orbitals, however, MOs are associated with an entire molecule, not with a single atom.

Learning Objectives

When you finish Section 9.7, you should be able to:

- Describe the characteristics of the bonding and antibonding molecular orbitals of the H_2 molecule.
- Interpret the energy-level diagram for the H_2 molecule and related molecules and molecular ions.

Molecular Orbitals of the Hydrogen Molecule

We begin our study of MO theory with the hydrogen molecule, H_2. The two 1*s* atomic orbitals (one on each H atom) are used to construct molecular orbitals for H_2. *Whenever two atomic orbitals overlap, two molecular orbitals form*. Thus, the overlap of the 1*s* orbitals of two hydrogen atoms to form H_2 produces two MOs. The first MO, which is shown at the bottom right of **Figure 9.31**, is formed by adding the wave functions for the two 1*s* orbitals. We refer to this as *constructive combination*. The energy of the resulting MO is lower in energy than the two atomic orbitals from which it was made. It is called the **bonding molecular orbital**.

The second MO is formed by what is called *destructive combination:* combining the two atomic orbitals in a way that causes the electron density to be canceled in the central region where the two overlap. The process is discussed more fully in the "Closer Look" box

Go Figure What is the probability of finding an electron at the nodal plane in the antibonding orbital?

Constructive combination leads to bonding H_2 molecular orbital.

▲ **Figure 9.31 The two molecular orbitals of H_2.** The one that is lower in energy is a bonding MO, whereas the other is an antibonding MO.

later in the chapter. The energy of the resulting MO, referred to as the **antibonding molecular orbital**, is higher than the energy of the atomic orbitals. The antibonding MO of H_2 is shown at the top right in Figure 9.31.

As illustrated in Figure 9.31, in the bonding MO electron density is concentrated in the region between the two nuclei. This sausage-shaped MO results from summing the two atomic orbitals so that the atomic orbital wave functions combine in the region between the two nuclei. Because an electron in this MO is attracted to both nuclei, the electron is more stable (it has lower energy) than it is in the 1*s* atomic orbital of an isolated hydrogen atom. Further, because this bonding MO concentrates electron density between the nuclei, it holds the atoms together in a covalent bond.

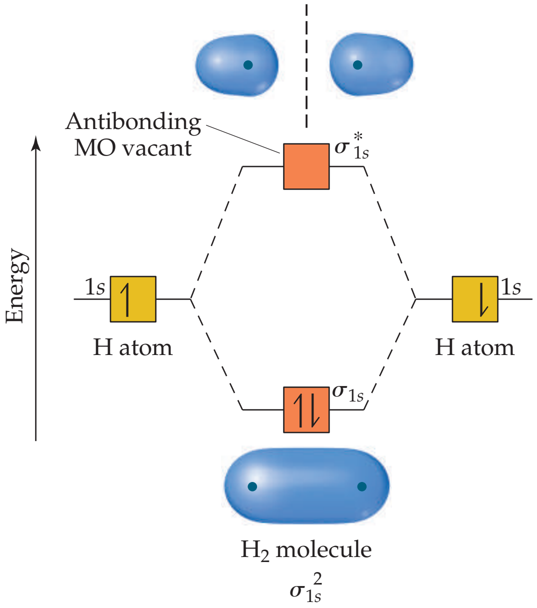
By contrast, the antibonding MO does the very opposite of a bonding MO: It actually excludes electron density between the nuclei. Instead of combining in the region between the nuclei, the atomic orbital wave functions cancel each other in this region, leaving the greatest electron density on opposite sides of the two nuclei. Instead of promoting the formation of a bond, an electron in an antibonding MO is actively discouraged from being involved in bonding. Antibonding orbitals invariably have a *plane* in the region between the nuclei where the electron density is zero. This plane is called a **nodal plane** of the MO. (Section 6.6) (The nodal plane is shown as a dashed line in Figure 9.31 and subsequent figures.) An electron in an antibonding MO is repelled from the bonding region and is therefore less stable (it has higher energy) than it is in the 1*s* atomic orbital of a hydrogen atom.

Notice from Figure 9.31 that the electron density in both the bonding MO and the antibonding MO of H_2 is centered about the internuclear axis. MOs of this type are called **sigma (σ) molecular orbitals** (by analogy to σ bonds). The bonding sigma MO of H_2 is labeled σ_{1s}, where the subscript indicates that the MO is formed from two 1*s* orbitals. The antibonding sigma MO of H_2 is labeled σ^*_{1s} (read "sigma-star-one-*s*"), where the asterisk denotes that the MO is antibonding.

The relative energies of two 1*s* atomic orbitals and the molecular orbitals formed from them are represented by an **energy-level diagram** (also called a **molecular-orbital diagram**). Such diagrams show the interacting atomic orbitals on the left and right and the MOs in the middle, as shown in **Figure 9.32**. Like atomic orbitals, each MO can accommodate two electrons with their spins paired (Pauli exclusion principle). (Section 6.7)

Go Figure

What would happen to the energy of the σ_{1s} MO if the H atoms in H_2 were pulled apart to a distance twice as long as its normal bond length?



▲ **Figure 9.32 Energy-level diagram and electron configuration for H_2.**

As the MO diagram for H_2 in Figure 9.32 shows, each H atom has one electron, so there are two electrons in H_2. These two electrons occupy the lower-energy bonding (σ_{1s}) MO, and their spins are paired. Electrons occupying a bonding molecular orbital are called *bonding electrons*. Because the σ_{1s} MO is lower in energy than the H 1*s* atomic orbitals, the H_2 molecule is more stable than the two separate H atoms. By analogy with atomic electron configurations, the electron configurations for molecules can be written with superscripts to indicate electron occupancy. In the MO model, we therefore write the electron configuration for H_2 as σ_{1s}^2.

In constructing hybrid orbitals, which we discussed earlier in this chapter, and in constructing molecular orbitals, we are mathematically mixing atomic orbitals to create new orbitals. It is important to recognize that while both hybrids and MOs are models used to discuss bonding, they are distinctly different: In creating hybrids, we mix atomic orbitals that reside on the *same* atom. In creating MOs, we mix atomic orbitals from *different* atoms.

Bond Order

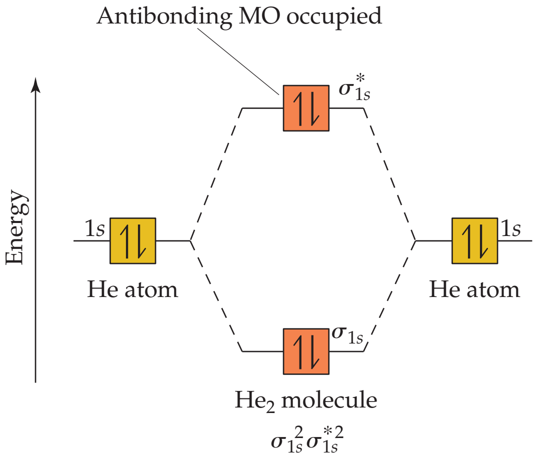
In molecular-orbital theory, the stability of a covalent bond is related to its **bond order**, defined as half the difference between the number of bonding electrons and the number of antibonding electrons:

$$\text{Bond order} = \tfrac{1}{2}(\text{number of bonding electrons} - \text{number of antibonding electrons}) \quad [9.1]$$

We take half the difference because we are used to thinking of bonds as pairs of electrons. *A bond order of 1 represents a single bond, a bond order of 2 represents a double bond, and a bond order of 3 represents a triple bond.* Because MO theory can also treat molecules containing an odd number of electrons, bond orders of 1/2, 3/2, or 5/2 are possible.

According to Figure 9.32, H_2 has two bonding electrons and zero antibonding electrons, so Equation 9.1 gives it a bond order of 1: $\frac{1}{2}(2 - 0) = 1$. How does this value compare to the bond order of He_2?

Figure 9.33 shows the energy-level diagram for the hypothetical He_2 molecule, which requires four electrons to fill its molecular orbitals. Because only two electrons can go in the σ_{1s} MO, the other two electrons must go in the σ_{1s}^* MO. The electron configuration of He_2 is thus $\sigma_{1s}^2\sigma_{1s}^{*2}$. The energy decrease realized in going from He atomic orbitals to the He bonding MO is offset by the energy increase realized in going from the atomic orbitals to the He antibonding MO.* Because He_2 has two bonding electrons and two antibonding electrons, it has a bond order of 0: $\frac{1}{2}(2 - 2) = 0$. A bond order of 0 means that no bond exists. Molecular-orbital theory correctly predicts that hydrogen forms diatomic molecules but helium does not.



◀ **Figure 9.33 Energy-level diagram and electron configuration for He_2.**

---

*Antibonding MOs are slightly more energetically unfavorable than bonding MOs are energetically favorable. Thus, whenever there is an equal number of electrons in bonding and antibonding orbitals, the energy of the molecule is slightly higher than that for the separated atoms. As a result, no bond is formed.

Sample Exercise 9.8

Bond Order

What is the bond order of the He_2^+ ion? Would you expect this ion to be stable relative to the separated He atom and He^+ ion?

SOLUTION

Analyze We will determine the bond order for the He_2^+ ion and use it to predict whether the ion is stable.

Plan To determine the bond order, we must determine the number of electrons in the molecule and how these electrons populate the available MOs. The valence electrons of He are in the 1*s* orbital, and the 1*s* orbitals combine to give an MO diagram like that for H_2 or He_2 (Figure 9.33). If the bond order is greater than 0, we expect a bond to exist, and the ion is stable.

Solve The energy-level diagram for the He_2^+ ion is shown in Figure 9.34. This ion has three electrons. Two are placed in the bonding orbital and the third in the antibonding orbital. Thus, the bond order is

$$\text{Bond order} = \tfrac{1}{2}(2 - 1) = \tfrac{1}{2}$$

Because the bond order is greater than 0, we predict the He_2^+ ion to be stable relative to the separated He and He_2^+. Formation of He_2^+ in the gas phase has been demonstrated in laboratory experiments.

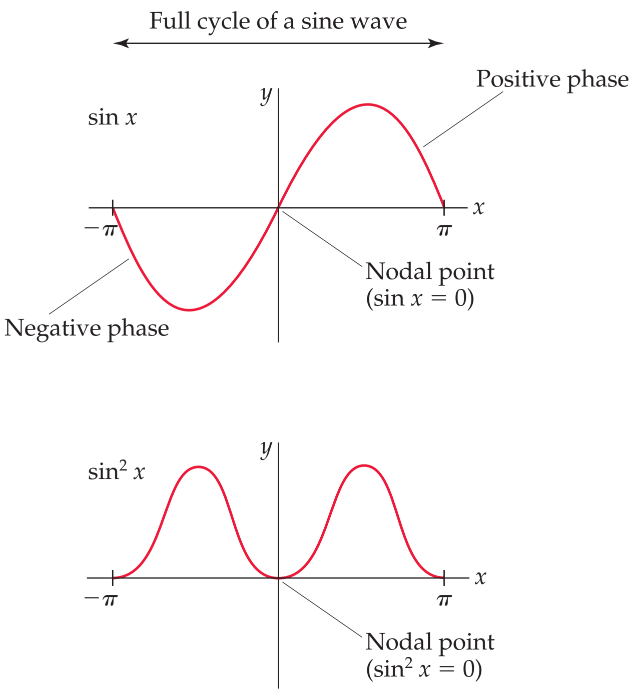
A CLOSER LOOK Phases in Atomic and Molecular Orbitals

Our discussion of atomic orbitals in Chapter 6 and molecular orbitals here in Chapter 9 highlights some of the most important applications of quantum mechanics in chemistry. In the quantum-mechanical treatment of electrons in atoms and molecules, we are mainly interested in determining two characteristics of the electrons—their energies and their distribution in space. Recall that solving Schrödinger's wave equation yields the electron's energy, *E*, and wave function, ψ, but that ψ does not have a direct physical meaning. (Section 6.5) The contour representations of atomic and molecular orbitals we have presented thus far are based on ψ^2 (the *probability density*), which gives the probability of finding the electron at a given point in space.

Because probability densities are squares of functions, their values must be nonnegative (zero or positive) at all points in space. However, the functions themselves can have negative values. The situation is like that of the sine function plotted in Figure 9.35. In the top graph, the sine function is negative for x between 0 and $-\pi$ and positive for x between 0 and $+\pi$. We say that the *phase* of the sine function is negative between 0 and $-\pi$ and positive between 0 and $+\pi$. If we square the sine function (bottom graph), we get two peaks that are symmetrical about the origin. Both peaks are positive because squaring a negative number produces a positive number. In other words, *we lose the phase information of the function upon squaring it*.

Like the sine function, the more complicated wave functions for atomic orbitals can also have phases. Consider, for example, the representations of the 1*s* orbital in Figure 9.36. Note that here we plot this orbital a bit differently from what is shown in Section 6.6. The origin is the point where the nucleus resides, and the wave function for the 1*s* orbital extends from the origin out into space. The plot shows the value of ψ for a slice taken along the *z*-axis. Below the plot is a contour representation of the 1*s* orbital. Notice that the value of the 1*s* wave function is always a positive number (we show positive values in red in Figure 9.36). Thus, it has only one phase. Notice also that the wave function approaches zero only at a long distance from the nucleus. It therefore has no nodes, as we saw in Figure 6.19.

In the graph for the $2p_z$ orbital in Figure 9.36, the wave function changes sign when it passes through $z = 0$. Notice that the two halves of the wave have the same shape except that one has positive



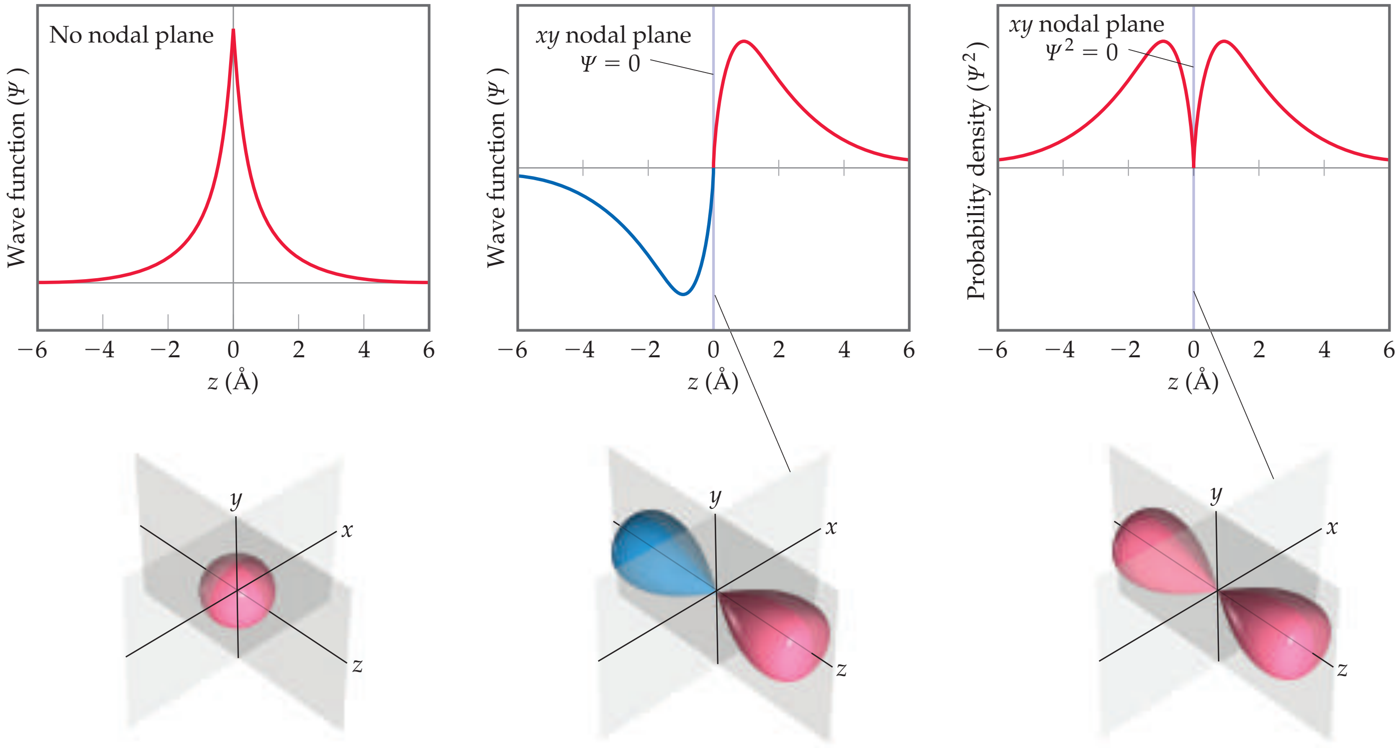
▲ **Figure 9.35** **Graphs for a sine function and the same function squared.**

(red) values and the other negative (blue) values. Analogously to the sine function, the wave function changes phase when it passes through the origin. Mathematically, the $2p_z$ wave function is equal to zero whenever $z = 0$. This corresponds to any point on the *xy* plane, so we say that the *xy* plane is a *nodal plane* of the $2p_z$ orbital. The wave function for a *p* orbital is much like a sine function because it has two equal parts that have opposite phases. Figure 9.36 gives a typical representation used by chemists of the wave function for a p_z orbital.* The red and blue lobes indicate the different phases of the orbital. (Note: The colors do *not* represent charge, as they did in the plots in Figures 9.10 and 9.11.) As with the sine function, the origin is a node.

The third graph in Figure 9.36 shows that when we square the wave function of the $2p_z$ orbital, we get two peaks that are symmetrical about the origin. Both peaks are positive because squaring a negative number produces a positive number. Thus, *we lose the phase information of the function upon squaring it* just as we did for the sine function. When we square the wave function for the p_z orbital, we get the probability density for the orbital, which is given as a contour representation in Figure 9.36. This is what we saw in the earlier presentation of *p* orbitals. (Section 6.6) For this squared wave function, both lobes have the same phase and therefore the same sign. We use this representation throughout most of this book because it has a simple physical interpretation: The square of the wave function at any point in space represents the electron density at that point.

The lobes of the wave functions for the *d* orbitals also have different phases. For example, the wave function for a d_{xy} orbital has four lobes, with the phase of each lobe opposite the phase of its nearest neighbors (**Figure 9.37**). The wave functions for the other *d* orbitals likewise have lobes in which the phase in one lobe is opposite that in an adjacent lobe.

Why do we need to consider the complexity introduced by considering the phase of the wave function? While it is true that the phase is not necessary to visualize the shape of an atomic orbital in an isolated atom, it does become important when we consider the



1*s* orbital

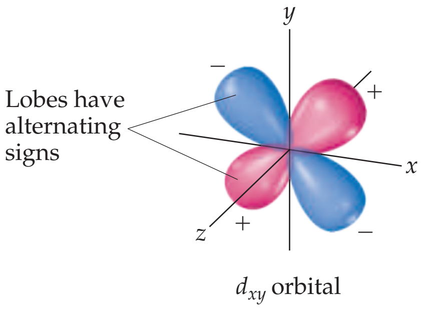
Continued

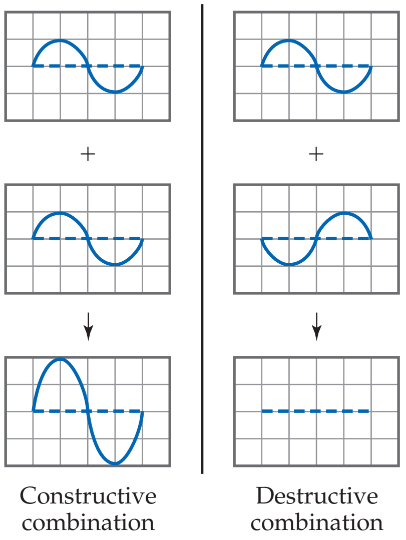
---

*The mathematical development of this three-dimensional function (and its square) is beyond the scope of this book, and, as is typically done by chemists, we have used lobes that are the same shape as in Figure 6.21.

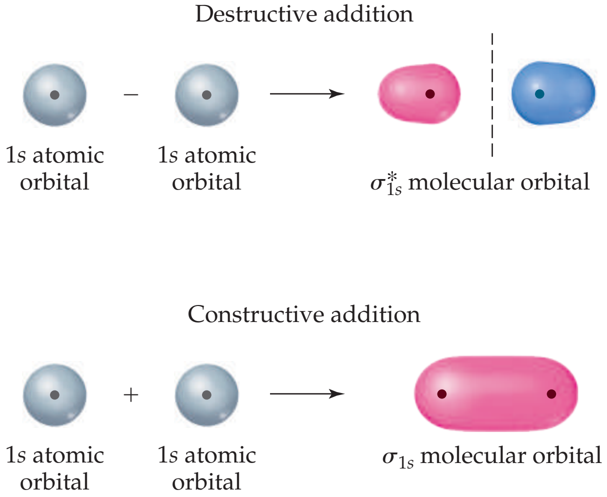


▲ **Figure 9.37** **Phases in *d* orbitals.**

overlap of orbitals in molecular-orbital theory. Let's use the sine function as an example again. If you add two sine functions having the same phase, they add *constructively,* resulting in increased amplitude:



but if you add two sine functions having opposite phases, they add *destructively* and cancel each other.



▲ **Figure 9.38** **Molecular orbitals from atomic orbital wave functions.**

The idea of constructive and destructive interactions of wave functions is key to understanding the origin of bonding and antibonding molecular orbitals. For example, the wave function of the σ_{1s} MO of H_2 is generated by adding the wave function for the 1*s* orbital on one atom to the wave function for the 1*s* orbital on the other atom, with both orbitals having the same phase. The atomic wave functions overlap *constructively* in this case to increase the electron density between the two atoms (**Figure 9.38**). The wave function of the σ^*_{1s} MO of H_2 is generated by subtracting the wave function for a 1*s* orbital on one atom from the wave function for a 1*s* orbital on the other atom. The result is that the atomic orbital wave functions overlap *destructively* to create a region of zero electron density between the two atoms—a node. Notice the similarity between this figure and Figure 9.32. In Figure 9.38, we use red and blue shading to denote positive and negative phases in the H atomic orbitals. However, chemists may alternatively draw contour representations in different colors, or with one phase shaded and one unshaded, to denote the two phases.

When we square the wave function of the σ^*_{1s} MO, we get the electron density representation which we saw earlier, in Figure 9.32. Notice once again that we lose the phase information by squaring the wave function when we look at the electron density.

The wave functions of atomic and molecular orbitals are used by chemists to understand many aspects of chemical bonding, spectroscopy, and reactivity. If you take a course in organic chemistry, you will probably see orbitals drawn to show the phases as in this box.

9.8 | Molecular-Orbital Description of Period 2 Diatomic Molecules

Learning Objectives

When you finish Section 9.8, you should be able to:

- Describe the principles for using molecular orbitals for atoms with more than 1*s* atomic orbitals.
- Construct the energy-level diagram for molecules in which both the 1*s* and 2*s* orbitals contribute to the molecular orbitals.
- Construct molecular orbitals from 2*p* atomic orbitals.
- Use MO theory to determine the electron configurations and properties for period 2 diatomic molecules.

In considering the MO description of diatomic molecules other than H_2, we initially restrict our discussion to *homonuclear* diatomic molecules (those composed of two identical atoms) of period 2 elements.

Period 2 atoms have valence 2*s* and 2*p* orbitals, and we need to consider how they interact to form MOs. The following rules summarize some of the guiding principles for the formation of MOs and for how they are populated by electrons:

1. The number of MOs formed equals the number of atomic orbitals combined.
2. Atomic orbitals combine most effectively with other atomic orbitals of similar energy.
3. The effectiveness with which two atomic orbitals combine is proportional to their overlap. That is, as the overlap increases, the energy of the bonding MO is lowered and the energy of the antibonding MO is raised.

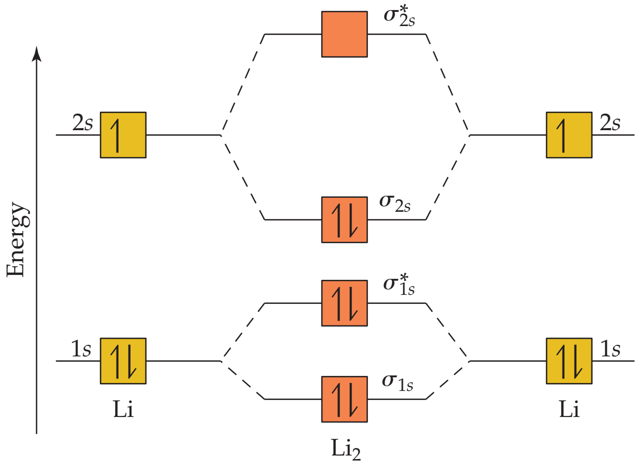
4. Each MO can accommodate, at most, two electrons, with their spins paired (Pauli exclusion principle). (Section 6.7)
5. When MOs of the same energy are populated, one electron enters each orbital (with the same spin) before spin pairing occurs (Hund's rule). (Section 6.8)

Molecular Orbitals for Li_2 and Be_2

Lithium has the electron configuration $1s^22s^1$. When lithium metal is heated above its boiling point (1342 °C), Li_2 molecules are found in the vapor phase. The Lewis structure for Li_2 indicates a Li—Li single bond. We now use MOs to describe the bonding in Li_2.

Go Figure

Which of the MOs in the diagram will have nodal planes?



▲ **Figure 9.39** **Energy-level diagram for the Li_2 molecule.**

Figure 9.39 shows that the Li 1*s* and 2*s* atomic orbitals have substantially different energy levels. From this, we can assume that the interaction of a 1*s* orbital on one Li atom with a 2*s* orbital on the other Li atom is negligible (rule 2). More generally, because of the large energy separation between core and valence orbitals, we usually assume that core orbitals interact only with core orbitals and valence orbitals interact only with valence orbitals.

Combining the two atomic orbitals on each of two Li atoms produces four MOs (rule 1). The Li 1*s* orbitals combine to form σ_{1s} and σ^*_{1s} bonding and antibonding MOs, as they did for H_2. The 2*s* orbitals interact with one another in exactly the same way, producing bonding (σ_{2s}) and antibonding (σ^*_{2s}) MOs. In general, the separation between bonding and antibonding MOs depends on the extent to which the interacting atomic orbitals overlap. Because the Li 2*s* orbitals extend farther from the nucleus than do the 1*s* orbitals, the 2*s* orbitals overlap more effectively. (Figure 6.19) As a result, the energy difference between the σ_{2s} and σ^*_{2s} orbitals is greater than the energy difference between the σ_{1s} and σ^*_{1s} orbitals. The 1*s* orbitals of Li are much lower in energy than the 2*s* orbitals, so the energy of the σ^*_{1s} antibonding MO is much lower than the energy of the σ_{2s} bonding MO.

Each Li atom has three electrons, so six electrons must be placed in Li_2 MOs. As shown in Figure 9.39, these electrons occupy the σ_{1s}, σ^*_{1s}, and σ_{2s} MOs, each with two electrons. There are four electrons in bonding orbitals and two in antibonding orbitals, so the bond order is $\frac{1}{2}(4 - 2) = 1$. The molecule has a single bond, in agreement with its Lewis structure.

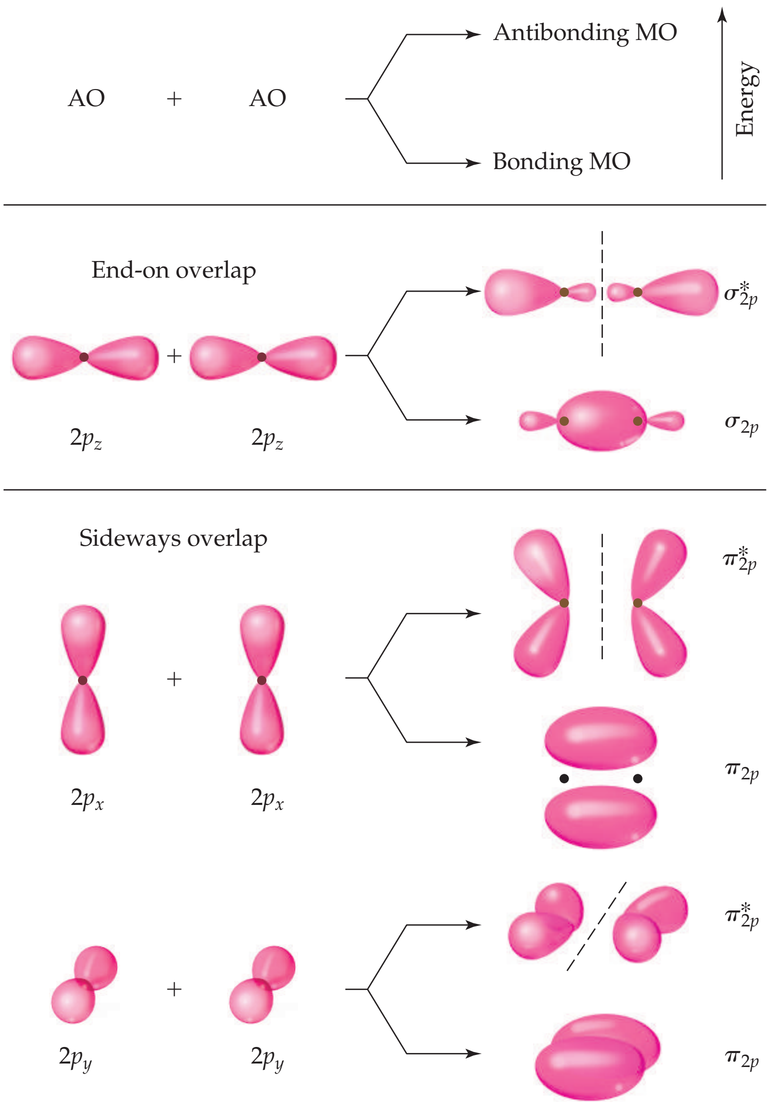
Because both the σ_{1s} and σ^*_{1s} MOs of Li_2 are completely filled, the 1*s* orbitals contribute virtually nothing to the bonding. The single bond in Li_2 is due essentially to the interaction of the valence 2*s* orbitals on the Li atoms. This example illustrates the general rule that *core electrons usually do not contribute significantly to bonding in molecules*. The rule is equivalent to using only the valence electrons when drawing Lewis structures. Thus, we need not consider further the 1*s* orbitals while discussing the other period 2 diatomic molecules.

The MO description of Be_2 follows readily from the energy-level diagram for Li_2. Each Be atom has four electrons ($1s^22s^2$), so we must place eight electrons in molecular orbitals. Therefore, we completely fill the σ_{1s}, σ^*_{1s}, σ_{2s}, and σ^*_{2s} MOs. With equal numbers of bonding and antibonding electrons, the bond order is zero; thus, Be_2 does not exist.

Molecular Orbitals from 2*p* Atomic Orbitals

Before we can consider the remaining period 2 diatomic molecules, we must look at the MOs that result from combining 2*p* atomic orbitals. The interactions between *p* orbitals are shown in **Figure 9.40**, where we have arbitrarily chosen the internuclear axis to be the *z* axis. The $2p_z$ orbitals face each other head to head. Just as with *s* orbitals, we can combine $2p_z$ orbitals in two ways. One combination concentrates electron density between the nuclei and is, therefore, a bonding molecular orbital. The other combination

Go Figure In which MO is the overlap of atomic orbitals greater, a σ_{2p} or a π_{2p}?



▲ **Figure 9.40 Contour representations of the molecular orbitals formed by 2*p* orbitals.**

excludes electron density from the bonding region and so is an antibonding molecular orbital. In both MOs, the electron density lies along the internuclear axis, so they are σ molecular orbitals: σ_{2p} and σ^*_{2p}. Notice that the σ^*_{2p} MO has a nodal plane halfway between the nuclei.

The other $2p$ orbitals overlap sideways and thus concentrate electron density above and below the internuclear axis. MOs of this type are called **pi (π) molecular orbitals** by analogy to π bonds. We get one π bonding MO by combining the $2p_x$ atomic orbitals and another from the $2p_y$ atomic orbitals. These two π_{2p} molecular orbitals have the same energy—they are degenerate. Likewise, we get two degenerate π^*_{2p} antibonding MOs that are perpendicular to each other like the $2p$ orbitals from which they were made. Each of these π^*_{2p} orbitals has four lobes, pointing away from the two nuclei, and a nodal plane, as shown in Figure 9.40.

The $2p_z$ orbitals on the two atoms point directly at each other. Hence, overlap of the two $2p_z$ orbitals is greater than that of the two $2p_x$ or $2p_y$ orbitals. We therefore expect the σ_{2p} MO to be lower in energy (more stable) than the π_{2p} MOs. Similarly, the σ^*_{2p} MO should be higher in energy (less stable) than the π^*_{2p} MOs.

Electron Configurations for B_2 through Ne_2

We can combine our analyses of MOs formed from *s* orbitals (Figure 9.32) and from *p* orbitals (Figure 9.40) to construct an energy-level diagram (**Figure 9.41**) for homonuclear diatomic molecules of the elements boron through neon, all of which have valence 2*s* and 2*p* atomic orbitals. The following features of the diagram are notable:

- The 2*s* atomic orbitals are substantially lower in energy than the 2*p* atomic orbitals. (Section 6.7) Consequently, both MOs formed from the 2*s* orbitals are lower in energy than the lowest-energy MO derived from the 2*p* atomic orbitals.
- The overlap of the two $2p_z$ orbitals is greater than that of the two $2p_x$ or $2p_y$ orbitals. As a result, the bonding σ_{2p} MO is lower in energy than the π_{2p} MOs, and the antibonding σ^*_{2p} MO is higher in energy than the π^*_{2p} MOs.
- Both the π_{2p} and π^*_{2p} MOs are *doubly degenerate*; that is, there are two degenerate MOs of each type.

Before we can add electrons to Figure 9.41, we must consider one more effect. We have constructed the diagram assuming no interaction between the 2*s* orbital on one atom and the 2*p* orbitals on the other. In fact, such interactions can and do take place. **Figure 9.42** shows the overlap of a 2*s* orbital on one of the atoms with a 2*p* orbital on the other. These interactions increase the energy difference between the σ_{2s} and σ_{2p} MOs, with the σ_{2s} energy decreasing and the σ_{2p} energy increasing (Figure 9.42). These 2*s*–2*p* interactions can be strong enough that the energetic ordering of the MOs can be altered: For B_2, C_2, and N_2, the σ_{2p} MO is *above* the π_{2p} MOs in energy. For O_2, F_2, and Ne_2, however, the σ_{2p} MO is *below* the π_{2p} MOs.

Given the energy ordering of the molecular orbitals, it is a simple matter to determine the electron configurations for the diatomic molecules B_2 through Ne_2. For example, a boron atom has three valence electrons. (Remember that we are ignoring the core 1*s* electrons.) Thus, for B_2 we must place six electrons in MOs. Four of them fill the σ_{2s} and σ^*_{2s} MOs, leading to no net bonding. The fifth electron goes in one π_{2p} MO, and the

Go Figure Why are the π^*_{2p} MOs lower in energy than the σ^*_{2p} MO?

sixth goes in the other π_{2p} MO, with the two electrons having the same spin. Therefore, B_2 has a bond order of 1.

Each time we move one element to the right in period 2, two more electrons must be placed in the diagram of Figure 9.41. For example, on moving to C_2, we have two more electrons than in B_2, and these electrons are placed in the π_{2p} MOs, completely filling them. Because it has six electrons in bonding MOs and two electrons in antibonding MOs, the C_2 molecule has a bond order of 2. The electron configurations and bond orders for B_2 through Ne_2 are given in **Figure 9.43**.

Electron Configurations and Molecular Properties

The way a substance behaves in a magnetic field can in some cases provide insight into the arrangements of its electrons. Molecules with one or more unpaired electrons are attracted to a magnetic field. The more unpaired electrons in a species, the stronger the attractive force. This type of magnetic behavior is called **paramagnetism**.

Substances with no unpaired electrons are weakly repelled by a magnetic field. This property is called **diamagnetism**. The distinction between paramagnetism and diamagnetism is nicely illustrated in an older method for measuring magnetic properties (**Figure 9.44**). It involves weighing the substance in the presence and absence of a magnetic field. A paramagnetic substance appears to weigh more in the magnetic field, whereas a diamagnetic substance appears to weigh less. The magnetic behaviors observed for the period 2 diatomic molecules agree with the electron configurations shown in Figure 9.43.

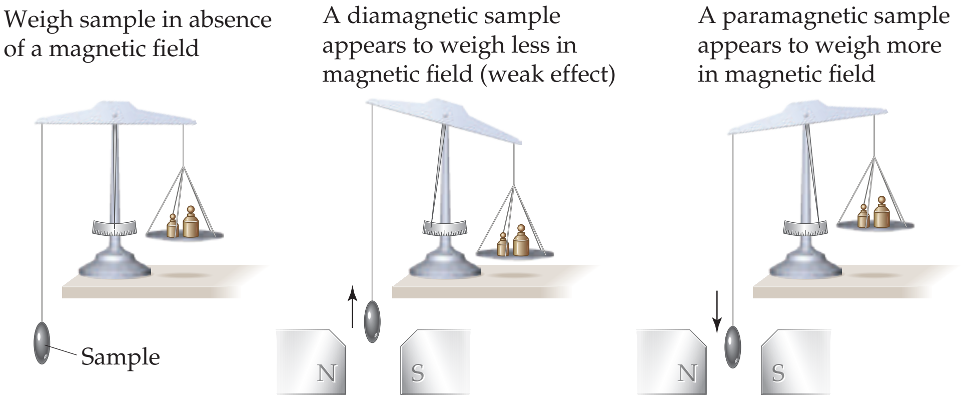
Electron configurations in molecules can also be related to bond distances and bond enthalpies. (Sections 5.8 and 8.8) As the bond order increases, bond distances decrease and bond enthalpies increase. N_2, for example, whose bond order is 3, has a short bond distance and a large bond enthalpy. The N_2 molecule does not react readily with other substances to form nitrogen compounds. The high bond order of the molecule helps explain its exceptional stability. Note, however, that molecules with the same bond orders do *not* have the same bond distances and bond enthalpies. Bond order is only one factor influencing these properties. Other factors include nuclear charge and extent of orbital overlap.

The bonding in O_2 provides an interesting test case for molecular-orbital theory. The Lewis structure for this molecule shows a double bond and complete pairing of electrons:

$$\underset{\cdot\cdot}{\ddot{\mathrm{O}}}=\underset{\cdot\cdot}{\ddot{\mathrm{O}}}$$

The short oxygen–oxygen bond distance (1.21 Å) and relatively high bond enthalpy (495 kJ/mol) are in agreement with the presence of a double bond. However, Figure 9.43 tells us that the molecule contains two unpaired electrons and should therefore be paramagnetic, a detail not discernible in the Lewis structure. The paramagnetism of O_2 is demonstrated in **Figure 9.45**, which confirms the prediction from MO theory. The MO description also correctly predicts a bond order of 2 as did the Lewis structure.

Going from O_2 to F_2, we add two electrons, completely filling the π^*_{2p} MOs. Thus, F_2 is expected to be diamagnetic and have an F—F single bond, in accord with its Lewis structure. Finally, the addition of two more electrons to make Ne_2 fills all the bonding and antibonding MOs. Therefore, the bond order of Ne_2 is zero, and the molecule is not expected to exist.



Weigh sample in absence of a magnetic field

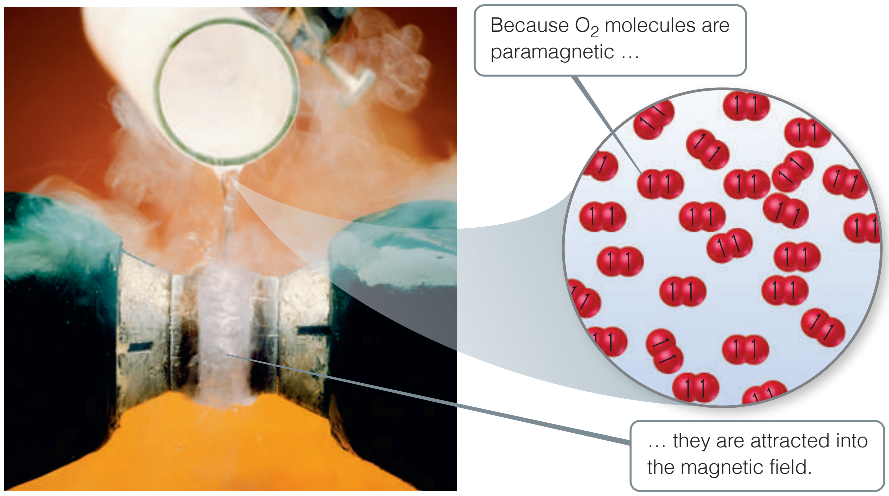
Go Figure What would you expect to see if liquid nitrogen were poured between the poles of the magnet?



Because O_2 molecules are paramagnetic …
… they are attracted into the magnetic field.

▲ **Figure 9.45 Paramagnetism of** O_2. When liquid oxygen is poured through a magnet, it "sticks" to the poles.

Sample Exercise 9.9

Molecular Orbitals of a Period 2 Diatomic Ion

For the O_2^+ ion predict (**a**) the number of unpaired electrons, (**b**) the bond order, and (**c**) the bond enthalpy and bond length.

SOLUTION

Analyze Our task is to predict several properties of the cation O_2^+.

Plan We will use the MO description of O_2^+ to determine the desired properties. We must first determine the number of electrons in O_2^+ and then draw its MO energy diagram. The unpaired electrons are those without a partner of opposite spin. The bond order is one-half the difference between the number of bonding and antibonding electrons. After calculating the bond order, we can use Figure 9.43 to estimate the bond enthalpy and bond length.

Solve

(**a**) The O_2^+ ion has 11 valence electrons, one fewer than O_2. The electron removed from O_2 to form O_2^+ is one of the two unpaired π_{2p}^* electrons (see Figure 9.43). Therefore, O_2^+ has one unpaired electron.

(**b**) The molecule has eight bonding electrons (the same as O_2) and three antibonding electrons (one fewer than O_2). Thus, its bond order is

$$\tfrac{1}{2}(8 - 3) = 2\tfrac{1}{2}$$

(**c**) The bond order of O_2^+ is between that for O_2 (bond order 2) and N_2 (bond order 3). Thus, the bond enthalpy and bond length should be about midway between those for O_2 and N_2, approximately 700 kJ/mol and 1.15 Å. (The experimentally measured values are 625 kJ/mol and 1.123 Å.)

▶ **Practice Exercise**

Predict the magnetic properties and bond orders of (**a**) the peroxide ion, O_2^{2-}; (**b**) the acetylide ion, C_2^{2-}.

Heteronuclear Diatomic Molecules

The principles we have used in developing an MO description of homonuclear diatomic molecules can be extended to *heteronuclear* diatomic molecules—those in which the two atoms in the molecule are not the same. We conclude this section with a fascinating heteronuclear diatomic molecule—nitric oxide, NO.

The NO molecule controls several important human physiological functions. Our bodies use it, for example, to relax muscles, kill foreign cells, and reinforce memory. The 1998 Nobel Prize in Physiology or Medicine was awarded to three scientists for their research that uncovered the importance of NO as a "signaling" molecule in the cardiovascular system. NO also functions as a neurotransmitter and is implicated in many other biological pathways. That NO plays such an important role in human metabolism was unsuspected before 1987 because NO has an odd number of electrons and is highly reactive. The molecule has 11 valence electrons, and two possible Lewis structures can be drawn. The Lewis structure with the lower formal charges places the odd electron on the N atom:

$$\overset{0}{\text{N}}=\overset{0}{\text{O}} \longleftrightarrow \overset{-1}{\text{N}}=\overset{+1}{\text{O}}$$

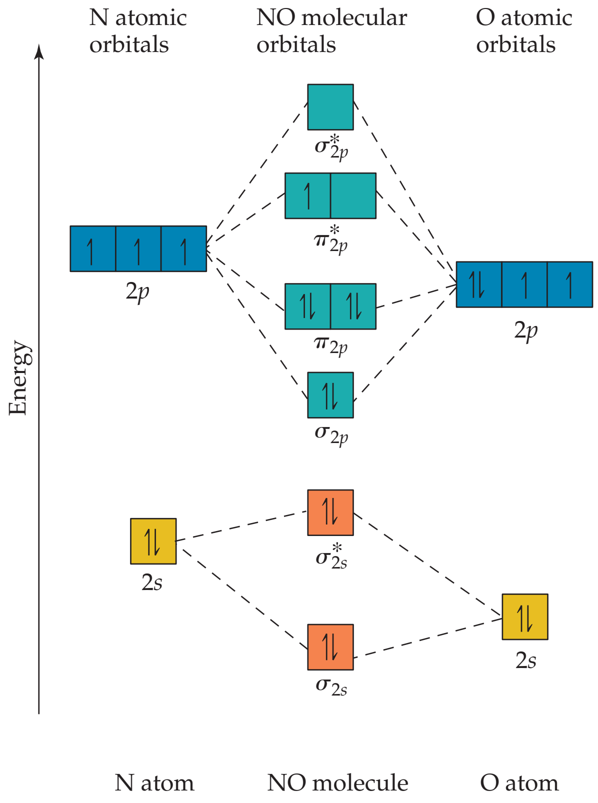
Both structures indicate the presence of a double bond, but when compared with the molecules in Figure 9.43, the experimental bond length of NO (1.15 Å) suggests a bond order greater than 2. How do we treat NO using the MO model?

If the atoms in a heteronuclear diatomic molecule do not differ too greatly in electronegativities, their MOs resemble those in homonuclear diatomics, with one important modification: The energy of the atomic orbitals of the more electronegative atom is lower than that of the atomic orbitals of the less electronegative element. In **Figure 9.46**, the 2*s* and 2*p* atomic orbitals of oxygen are slightly lower than those of nitrogen because oxygen is more electronegative than nitrogen. The MO energy-level diagram for NO is much like that of a homonuclear diatomic molecule—because the 2*s* and 2*p* orbitals on the two atoms interact, the same types of MOs are produced.

There is one other important difference in the MOs of heteronuclear molecules. The MOs are still a mix of atomic orbitals from both atoms, but in general an *MO in a heteronuclear diatomic molecule has a greater contribution from the atomic orbital to which it is closer in energy*. In the case of NO, for example, the σ_{2s} bonding MO is closer in energy to the O 2*s* atomic orbital than to the N 2*s* atomic orbital. As a result, the σ_{2s} MO has a slightly greater contribution from O than from N—the orbital is no longer an equal mixture of the two atoms, as was the case for the homonuclear diatomic molecules. Similarly, the σ^*_{2s} antibonding MO is weighted more heavily toward the N atom because that MO is closest in energy to the N 2*s* atomic orbital.

We complete the MO diagram for NO by filling the MOs in Figure 9.46 with the 11 valence electrons. Eight bonding and three antibonding electrons give a bond order

Go Figure How many valence-shell electrons are there in NO?



▲ **Figure 9.46** **The energy-level diagram for atomic and molecular orbitals in NO.**

CHEMISTRY AND SUSTAINABILITY Orbitals and Solar Energy

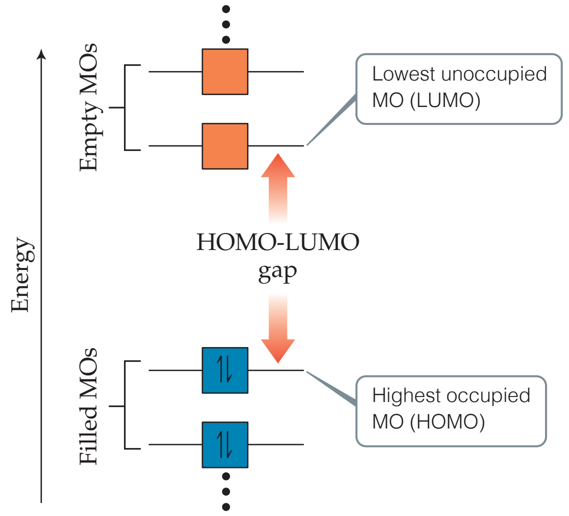
One of the United Nations Sustainable Development Goals is “Affordable and Clean Energy” (Figure 1.16). Indeed, one of our major technological challenges for the twenty-first century is the development of sustainable energy sources to meet the energy needs of future generations of people on our planet. One of the most remarkable sources of clean energy is the Sun, which sends enough energy to power the world for millions of years. Our challenge is to capture enough of this energy in a form that allows us to use it as needed. *Photovoltaic solar cells* convert the light from the Sun into usable electricity, and the development of more efficient solar cells is one way to address Earth’s future energy needs.

How does solar energy conversion work? Fundamentally, we need to be able to use photons from the Sun, especially from the visible portion of the spectrum, to excite electrons in molecules and materials to different energy levels. The brilliant colors around you—those of your clothes, the photographs in this book, the foods you eat—are due to the selective absorption of visible light by chemicals. It is helpful to think of this process in the context of molecular-orbital theory: Light excites an electron from a filled molecular orbital to an empty one at higher energy. Because MOs have definite energies, only light of the proper wavelengths can excite electrons, similar to what we saw in our discussion of atomic line spectra. (Section 6.3)

In discussing light absorption by molecules, we can focus on the two MOs shown in **Figure 9.47**. The *highest occupied molecular orbital* (HOMO) is the MO of highest energy that has electrons in it. The *lowest unoccupied molecular orbital* (LUMO) is the MO of lowest energy that does not have electrons in it. In N_2, for example, the HOMO is the σ_{2p} MO and the LUMO is the π^*_{2p} MO (Figure 9.43).

The energy difference between the HOMO and the LUMO—known as the HOMO–LUMO gap—is related to the minimum energy needed to excite an electron in the molecule. Colorless or white substances usually have such a large HOMO–LUMO gap that visible light is not energetic enough to excite an electron to the higher level. The minimum energy needed to excite an electron from the HOMO to the LUMO in N_2 corresponds to light with a wavelength of less than 200 nm, which is far into the ultraviolet part of the spectrum. (Figure 6.4) As a result, N_2 cannot absorb visible light and is therefore colorless.

The magnitude of the energy gap between filled and empty electronic states is critical for solar energy conversion. Ideally, we want a substance that absorbs as many solar photons as possible and then converts the energy of those photons into a useful form of energy. Titanium dioxide is a readily available material that can be reasonably efficient at converting light directly into electricity. However, TiO_2 is white and absorbs only a small amount of the Sun’s radiant energy. Scientists are working to make solar cells in which TiO_2 is mixed with highly colored molecules, whose HOMO–LUMO gaps correspond to visible and near-infrared light to absorb more of the solar spectrum. If the HOMO of these molecules is higher in energy than the HOMO of TiO_2, the excited electrons will flow from the molecules into the TiO_2. When this system is connected to an external circuit, the electron can flow to another cell where it adds back to the dye, restoring it to its original state. Thus, the energy of light can be used to cause a current of electricity to flow.



▲ **Figure 9.47 Definitions of the highest occupied and lowest unoccupied molecular orbitals** The energy difference between these is the HOMO–LUMO gap.

Efficient solar energy conversion promises to be one of the most interesting and important areas of both scientific and technological development in our future. Many of you may ultimately end up working in fields that have an impact on the world’s energy portfolio.

Related Exercises: 9.109, 9.112, Design an Experiment

of $\frac{1}{2}(8 - 3) = 2\frac{1}{2}$, which agrees better with experiment than the Lewis structures do. The unpaired electron resides in one of the π^*_{2p} MOs, which have a greater contribution from the N atom. (We could have placed this electron in either the left or right π^*_{2p} MO.) Thus, the Lewis structure that places the unpaired electron on nitrogen (the one preferred on the basis of formal charge) is the more accurate description of the true electron distribution in the molecule.

Self-Assessment Exercises

SAE 9.22 For the Li_2 molecule, rank-order the following orbitals from lowest to highest energy: $1s$, $2s$, σ_{2s}, σ^*_{2s}.

(a) $1s < 2s < \sigma_{2s} < \sigma^*_{2s}$
(b) $\sigma_{2s} < 1s < 2s < \sigma^*_{2s}$
(c) $1s < \sigma^*_{2s} < 2s < \sigma_{2s}$
(d) $1s < \sigma_{2s} < 2s < \sigma^*_{2s}$

SAE 9.23 Which of the following statements about the molecular orbitals for a diatomic molecule with $2s$ and $2p$ orbitals is or are *true*?

(i) The σ^*_{2p} molecular orbital is higher in energy than a π^*_{2p} molecular orbital because the overlap is greater for two $2p$ orbitals that point directly at one another.
(ii) The molecule has one σ_{2p} molecular orbital and one π_{2p} molecular orbital.
(iii) The σ_{2p} and π_{2p} molecular orbitals both have a lower energy than the $2p$ orbitals from which they were constructed.

(a) Only one of the statements is true. **(b)** Statements i and ii are true. **(c)** Statements i and iii are true. **(d)** Statements ii and iii are true. **(e)** All three statements are true.

SAE 9.24 For the N_2^- molecular ion, the number of electrons in the π^*_{2p} molecular orbitals is _____ and the bond order of the ion is _____. **(a)** 0, 3 **(b)** 3, 1.5 **(c)** 0, 2.5 **(d)** 1, 1.5 **(e)** 1, 2.5

Putting Concepts Together

Elemental sulfur is a yellow solid that consists of S_8 molecules. The structure of the S_8 molecule is a puckered, eight-membered ring (see Figure 7.27). Heating elemental sulfur to high temperatures produces gaseous S_2 molecules:

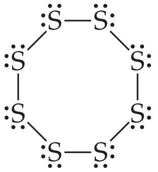
$$S_8(s) \longrightarrow 4\,S_2(g)$$

(a) The electron configuration of which period 2 element is most similar to that of sulfur? (b) Use the VSEPR model to predict the S—S—S bond angles in S_8 and the hybridization at S in S_8. (c) Use MO theory to predict the sulfur–sulfur bond order in S_2. Do you expect this molecule to be diamagnetic or paramagnetic? (d) Use average bond enthalpies (Table 8.3) to estimate the enthalpy change for this reaction. Is the reaction exothermic or endothermic?

SOLUTION

(a) Sulfur is a group 6A element with an $[\mathrm{Ne}]3s^23p^4$ electron configuration. It is expected to be most similar electronically to oxygen (electron configuration, $[\mathrm{He}]2s^22p^4$), which is immediately above it in the periodic table.

(b) The Lewis structure of S_8 is



There is a single bond between each pair of S atoms and two nonbonding electron pairs on each S atom. Thus, we see four electron domains around each S atom and expect a tetrahedral electron-domain geometry corresponding to sp^3 hybridization. Because of the nonbonding pairs, we expect the S—S—S angles to be somewhat less than 109.5°, the tetrahedral angle. Experimentally, the S—S—S angle in S_8 is 108°, in good agreement with this prediction. Interestingly, if S_8 were a planar ring, it would have S—S—S angles of 135°. Instead, the S_8 ring puckers to accommodate the smaller angles dictated by sp^3 hybridization.

(c) The MOs of S_2 are analogous to those of O_2, although the MOs for S_2 are constructed from the $3s$ and $3p$ atomic orbitals of sulfur. Further, S_2 has the same number of valence electrons as O_2. Thus, by analogy with O_2, we expect S_2 to have a bond order of 2 (a double bond) and to be paramagnetic with two unpaired electrons in the π^*_{3p} molecular orbitals of S_2.

(d) We are considering the reaction in which an S_8 molecule falls apart into four S_2 molecules. From parts (b) and (c), we see that S_8 has S—S single bonds and S_2 has S═S double bonds. During the reaction, therefore, we are breaking eight S—*S* single bonds and forming four S═S double bonds. We can estimate the enthalpy of the reaction by using Equation 5.32 and the average bond enthalpies in Table 8.3:

$$\begin{aligned}\Delta H_{\mathrm{rxn}} &= \Sigma(\text{bond enthalpies of bonds broken}) - \\ &\quad\ \Sigma(\text{bond enthalpies of bonds formed}) \\ &= 8D\,(\mathrm{S{-}S}) - 4\,D(\mathrm{S{=}S}) \\ &= 8(266\ \mathrm{kJ}) - 4(418\ \mathrm{kJ}) = +456\ \mathrm{kJ}\end{aligned}$$

Recall that $D(X—Y)$ represents the $X—Y$ bond enthalpy. Because $\Delta H_{\mathrm{rxn}} > 0$, the reaction is endothermic (Section 5.3). The very positive value of ΔH_{rxn} suggests that high temperatures are required to cause the reaction to occur.

Chapter Summary and Key Terms

MOLECULAR SHAPES (INTRODUCTION AND SECTION 9.1) The three-dimensional shapes and sizes of molecules are determined by their **bond angles** and bond lengths. Molecules with a central atom A surrounded by n atoms B, denoted AB_n, adopt a number of different geometric shapes, depending on the value of n and on the particular atoms involved. In the overwhelming majority of cases, these geometries are related to five basic shapes (linear, trigonal pyramidal, tetrahedral, trigonal bipyramidal, and octahedral).

THE VSEPR MODEL (SECTION 9.2) The **valence-shell electron-pair repulsion (VSEPR) model** rationalizes molecular geometries based on the repulsions between **electron domains**, which are regions about a central atom in which electrons are likely to be found. **Bonding pairs** of electrons, which are those involved in making bonds, and **nonbonding pairs** of electrons, also called **lone pairs**, both create electron domains around an atom. According to the VSEPR model, electron domains orient themselves to minimize electrostatic repulsions; that is, they remain as far apart as possible.

Electron domains from nonbonding pairs exert slightly greater repulsions than those from bonding pairs, which leads to certain preferred positions for nonbonding pairs and to the departure of bond angles from idealized values. Electron domains from multiple bonds exert slightly greater repulsions than those from single bonds. The arrangement of electron domains around a central atom is called the **electron-domain geometry**; the arrangement of atoms is called the **molecular geometry**.

MOLECULAR POLARITY (SECTION 9.3) The dipole moment of a polyatomic molecule depends on the vector sum of the dipole moments associated with the individual bonds, called the **bond dipoles**. Certain molecular shapes, such as linear AB_2 and trigonal-planar AB_3, lead to cancellation of the bond dipoles, producing a nonpolar molecule (one whose overall dipole moment is zero). In other shapes, such as bent AB_2 and trigonal pyramidal AB_3, the bond dipoles do *not* cancel and the molecule will be polar (that is, it will have a nonzero dipole moment).

COVALENT BONDING AND VALENCE-BOND THEORY (SECTION 9.4) **Valence-bond theory** is an extension of Lewis's notion of electron-pair bonds. In valence-bond theory, covalent bonds are formed when atomic orbitals on neighboring atoms overlap one another. The overlap region is one of greater stability for the two electrons because of their simultaneous attraction to two nuclei. The greater the overlap between two orbitals, the stronger the bond that is formed.

HYBRID ORBITALS (SECTION 9.5) To extend the ideas of valence-bond theory to polyatomic molecules, we must envision mixing *s* and *p* orbitals to form **hybrid orbitals**. The process of **hybridization** leads to hybrid atomic orbitals that have a large lobe directed to overlap with orbitals on another atom to make a bond. Hybrid orbitals can also accommodate nonbonding pairs. A particular mode of hybridization can be associated with each of three common electron-domain geometries (linear = *sp*; trigonal planar = sp^2; tetrahedral = sp^3). The bonding in **hypervalent** molecules—those with more than an octet of electrons—is not as readily discussed in terms of hybrid orbitals.

MULTIPLE BONDS (SECTION 9.6) Covalent bonds in which the electron density lies along the line connecting the atoms (the internuclear axis) are called **sigma (σ) bonds**. Bonds can also be formed from the sideways overlap of *p* orbitals. Such a bond is called a **pi (π) bond**. A double bond, such as that in C_2H_4, consists of one σ bond and one π bond; each carbon atom has an unhybridized *p* orbital, and these are the orbitals that overlap to form π bonds. A triple bond, such as that in C_2H_2, consists of one σ and two π bonds. The formation of a π bond requires that molecules adopt a specific orientation; the two CH_2 groups in C_2H_4, for example, must lie in the same plane. As a result, the presence of π bonds introduces rigidity into molecules. In molecules that have multiple bonds and more than one resonance structure, such as C_6H_6, the π system is **delocalized**; that is, the π electrons are spread among several atoms.

MOLECULAR ORBITALS (SECTION 9.7) **Molecular-orbital theory** is another model used to describe the bonding in molecules. In this model, the electrons exist in allowed energy states called **molecular orbitals (MOs)**. An MO can extend over all the atoms of a molecule. Like an atomic orbital, a molecular orbital has a definite energy and can hold two electrons of opposite spin. We can build molecular orbitals by combining atomic orbitals on different atomic centers. In the simplest case, the combination of two atomic orbitals leads to the formation of two MOs, one at lower energy and one at higher energy relative to the energy of the atomic orbitals. The lower-energy MO concentrates charge density in the region between the nuclei and is called a **bonding molecular orbital**. The higher-energy MO excludes electrons from the region between the nuclei and is called an **antibonding molecular orbital**. Antibonding MOs have a **nodal plane**—a place at which the electron density is zero—between the nuclei. Occupation of bonding MOs favors bond formation, whereas occupation of antibonding MOs is unfavorable. The bonding and antibonding MOs formed by the combination of *s* orbitals are **sigma (σ) molecular orbitals**; they lie on the internuclear axis.

The combination of atomic orbitals and the relative energies of the molecular orbitals are shown by an **energy-level** (or **molecular-orbital**) **diagram**. When the appropriate number of electrons is put into the MOs, we can calculate the **bond order** of a bond, which is half the difference between the number of electrons in bonding MOs and the number of electrons in antibonding MOs. A bond order of 1 corresponds to a single bond, and so forth. Bond orders can be fractional numbers.

MOLECULAR-ORBITAL DESCRIPTION OF PERIOD 2 DIATOMIC MOLECULES (SECTION 9.8) Electrons in core orbitals do not contribute to the bonding between atoms, so a molecular-orbital description usually needs to consider only the valence electrons. To describe the MOs of period 2 homonuclear diatomic molecules, we need to consider the MOs that can form by the combination of *p* orbitals. The *p* orbitals that point directly at one another can form σ bonding and σ^* antibonding MOs. The *p* orbitals that are oriented perpendicular to the internuclear axis combine to form **pi (π) molecular orbitals**. In diatomic molecules, the π molecular orbitals occur as a pair of degenerate (same energy) bonding MOs and a pair of degenerate antibonding MOs. The σ_{2p} bonding MO is expected to be lower in energy than the π_{2p} bonding MOs because of larger orbital overlap of the *p* orbitals directed along the internuclear axis. However, this ordering is reversed in B_2, C_2, and N_2 because of interaction between the 2*s* and 2*p* atomic orbitals of different atoms.

The molecular-orbital description of period 2 diatomic molecules leads to bond orders in accord with the Lewis structures of these molecules. Further, the model predicts correctly that O_2 should exhibit **paramagnetism**; a paramagnetic molecule is attracted into a magnetic field due to the influence of unpaired electrons. Molecules in which all the electrons are paired exhibit **diamagnetism**; a diamagnetic molecule is weakly repelled from a magnetic field. The molecular orbitals of heteronuclear diatomic molecules are often closely related to those of homonuclear diatomic molecules.

Key Equations

- Bond order $= \frac{1}{2}$(number of bonding electrons − number of antibonding electrons) [9.1]

Exam Prep

EP 9.1 BF_3 is a trigonal-planar molecule, whereas PF_3 is a trigonal-pyramidal molecule. Which of the following statements about these two molecules is *false*? (**a**) All the F—B—F angles in BF_3 are 120°. (**b**) The F atoms in BF_3 sit on the vertices of an equilateral triangle. (**c**) The shape of PF_3 can be obtained by removing one atom from a tetrahedral arrangement of atoms. (**d**) The four atoms in BF_3 all lie in the same plane. (**e**) The four atoms in PF_3 all lie in the same plane.

EP 9.2 Consider the following AB_3 molecules and ions: PCl_3, SO_3, $AlCl_3$, SO_3^{2-}, and CH_3^+. How many of these molecules and ions do you predict to have a trigonal-planar molecular geometry? (**a**) 1 (**b**) 2 (**c**) 3 (**d**) 4 (**e**) 5

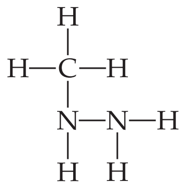
EP 9.3 Which of the following statements about the structure of H_2S is *false*? (**a**) H_2S has a trigonal-planar electron-domain geometry. (**b**) The Lewis structure of H_2S has eight valence electrons. (**c**) There are two nonbonding electron domains on the S atom in H_2S. (**d**) The H—S—H angle in H_2S is less than 109.5°.

EP 9.4 A certain AB_4 molecule has a square-planar molecular geometry. Which of the following statements about the molecule is or are *true*?

(**i**) The molecule has four electron domains about the central atom A.
(**ii**) The B—A—B angles between neighboring B atoms are 90°.
(**iii**) The molecule has two nonbonding pairs of electrons on atom A.

(**a**) Only one of the statements is true. (**b**) Statements i and ii are true. (**c**) Statements i and iii are true. (**d**) Statements ii and iii are true. (**e**) All three statements are true.

EP 9.5 The atoms of the compound methylhydrazine, CH_6N_2, which is used as a rocket propellant, are connected as shown (note that the lone pairs are not shown):



What do you predict for the ideal values (ignoring any effects from lone pairs) of the C—N—N and H—N—H angles, respectively? (**a**) 109.5° and 109.5° (**b**) 109.5° and 120° (**c**) 120° and 109.5° (**d**) 120° and 120° (**e**) None of the answers is correct.

EP 9.6 Which of the following statements about molecular polarity is or are *true*?

(**i**) The bond dipole is a vector quantity that has both a magnitude and a direction.

(**ii**) If a molecule has a nonzero bond dipole, then it will be a polar molecule.

(**iii**) The bond dipoles in a tetrahedral AB_4 molecule cancel one another, so the molecule is nonpolar.

(**a**) Only one of the statements is true. (**b**) Statements i and ii are true. (**c**) Statements i and iii are true. (**d**) Statements ii and iii are true. (**e**) All three statements are true.

EP 9.7 Consider an AB_3 molecule in which A and B differ in electronegativity. You are told that the molecule has an overall dipole moment of zero. Which of the following could be the molecular geometry of the molecule? (**a**) trigonal pyramidal (**b**) trigonal planar (**c**) T-shaped (**d**) tetrahedral (**e**) More than one of these geometries is possible.

EP 9.8 The bond length in Cl_2 is 1.99 Å. Which of the following statements about the valence-bond description of the Cl—Cl bond in Cl_2 is *false*? (**a**) The bond is formed from the overlap of a 3*p* orbital on one Cl atom with a 3*s* orbital on the other Cl atom. (**b**) The orbital overlap decreases as the Cl atoms are pulled apart. (**c**) At Cl—Cl distances less than 1.99 Å, the potential energy of the Cl_2 molecule increases because of the electrostatic repulsion between the two Cl atoms. (**d**) Each of the overlapping orbitals has one electron in it. (**e**) The potential energy of the Cl_2 molecule is at a minimum at a Cl—Cl distance of 1.99 Å.

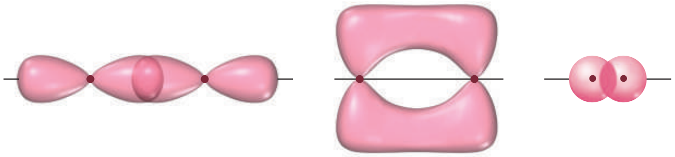
EP 9.9 Which of the following statements about atomic orbitals and hybrid orbitals is *true*?

(**a**) To make hybrid orbitals, we mix atomic orbitals on two different atoms. (**b**) Hybrid orbitals can allow us to make multiple equivalent bonds when atomic orbitals can't do so. (**c**) Each hybrid orbital has two lobes that are the same size. (**d**) The number of hybrid orbitals produced is greater than the number of atomic orbitals that are mixed. (**e**) Each hybrid orbital can hold a maximum of one electron.

EP 9.10 Fill in the blanks in the following sentences about the CH_2^{2+} ion: "The valence-bond description of CH_2^{2+} involves the overlap of the H 1*s* orbitals with ____ hybrid orbitals on the C atom. The predicted H—C—H angle in CH_2^{2+} is ____ degrees." (**a**) *sp*, 120 (**b**) sp^2, 120 (**c**) *sp*, 180 (**d**) sp^2, 180 (**e**) sp^3, 109.5

EP 9.11 For which of the following molecules or ions does the following description apply? "The σ bonding can be explained using a set of sp^2 hybrid orbitals on the central atom, with one of the hybrid orbitals holding a nonbonding pair of electrons." (**a**) CO_2 (**b**) H_2S (**c**) O_3 (**d**) CO_3^{2-} (**e**) more than one of the molecules or ions listed

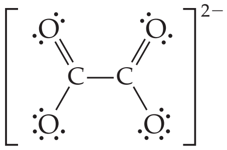
EP 9.12 Three types of orbital overlaps are illustrated in the figure. Which of these represent the formation of a σ bond? (**a**) only one of them (**b**) i and ii (**c**) i and iii (**d**) ii and iii (**e**) all three of them



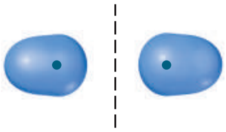
(i) (ii) (iii)

EP 9.13 Fill in the blanks in the following sentence about the hydrogen cyanide molecule, HCN: "In HCN, ____ electrons are used to make σ bonds and ____ electrons are used to make π bonds." (**a**) 2, 2 (**b**) 2, 4 (**c**) 2, 6 (**d**) 4, 2 (**e**) 4, 4

EP 9.14 A Lewis structure of the oxalate ion, $C_2O_4^{2-}$, is shown here. How many electrons are in the π system of the ion? (**a**) 2 (**b**) 4 (**c**) 6 (**d**) 8



EP 9.15 One of the molecular orbitals of the H_2 molecule is shown here. The label for this orbital is ____, and it is ____. (**a**) σ_{1s}, bonding (**b**) σ_{1s}, antibonding (**c**) σ^*_{1s}, bonding (**d**) σ^*_{1s}, antibonding

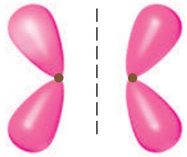


EP 9.16 Which of the following molecules and ions have a bond order of 1/2: H_2, H_2^+, H_2^-, and He_2^{2+}? (**a**) H_2 and H_2^+ (**b**) H_2^+ and H_2^- (**c**) H_2^- and He_2^{2+} (**d**) H_2, H_2^+, and H_2^- (**e**) H_2^+, H_2^-, and He_2^{2+}

EP 9.17 Which of the following statements about molecular-orbital theory is *false*? (**a**) The number of molecular orbitals for a molecule is less than the number of atomic orbitals that are used to make them. (**b**) Two atomic orbitals combine most effectively to make molecular orbitals when they have similar energies. (**c**) As the overlap of two atomic orbitals increases, the antibonding molecular orbital that arises from them becomes higher in energy. (**d**) A molecular orbital for a molecule can hold zero, one, or two electrons, depending on its energy and the number of electrons in the molecule. (**e**) The energy of a bonding molecular orbital is lower than the energy of the atomic orbitals from which it is made.

EP 9.18 In the molecular-orbital description of the Be_2^+ ion, the σ^*_{2s} MO has ____ electron(s) in it, and the bond order of the ion is ____. (**a**) 1, 0 (**b**) 2, 0 (**c**) 2, 1 (**d**) 2, ½ (**e**) 1, ½

EP 9.19 One of the molecular orbitals of a homonuclear diatomic molecule is shown here. Which of the following statements about this MO is or are *true*?



(**i**) This is a π^*_{2p} MO.

(**ii**) There is another molecular orbital for the molecule that has exactly the same energy as the one shown.

(**iii**) The energy of this molecular orbital is lower than the energy of the atomic orbitals from which it is formed.

(**a**) Only one of the statements is true. (**b**) Statements i and ii are true. (**c**) Statements i and iii are true. (**d**) Statements ii and iii are true. (**e**) All three statements are true.

EP 9.20 A homonuclear diatomic molecule has the following valence molecular-orbital electron configuration: $\sigma_{2s}^2\sigma_{2s}^{*2}\sigma_{2p}^2\pi_{2p}^4\pi_{2p}^{*2}$. What is the molecule, and is it diamagnetic or paramagnetic? (**a**) B_2, paramagnetic (**b**) N_2, diamagnetic (**c**) N_2, paramagnetic (**d**) O_2, diamagnetic (**e**) O_2, paramagnetic

EP 9.21 Place the following molecular ions in order from smallest to largest bond order: C_2^{2+}, N_2^-, O_2^-, F_2^-.

(**a**) $C_2^{2+} < N_2^- < O_2^- < F_2^-$

(**b**) $F_2^- < O_2^- < N_2^- < C_2^{2+}$

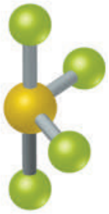
(**c**) $O_2^- < C_2^{2+} < F_2^- < N_2^-$

(**d**) $C_2^{2+} < F_2^- < O_2^- < N_2^-$

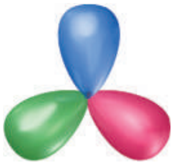
(**e**) $F_2^- < C_2^{2+} < O_2^- < N_2^-$

Exercises

Visualizing Concepts

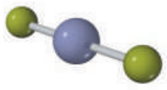


9.1 A certain AB_4 molecule has a “seesaw” shape. From which of the fundamental geometries shown in Figure 9.3 could you remove one or more atoms to create a molecule having this seesaw shape? [Section 9.1]

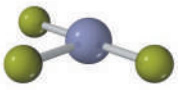


9.2 (**a**) If these three balloons are all the same size, what angle is formed between the red one and the green one? (**b**) If additional air is added to the blue balloon so that it gets larger, will the angle between the red and green balloons increase, decrease, or stay the same? (**c**) Which of the following aspects of the VSEPR model is illustrated by part (b): (i) The electron-domain geometry for four electron domains is tetrahedral. (ii) The electron domains for nonbonding pairs are larger than those for bonding pairs. (iii) The hybridization that corresponds to a trigonal-planar electron-domain geometry is sp^2. [Section 9.2]

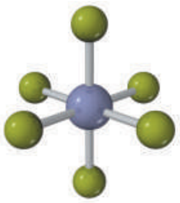
9.3 For each molecule (a)–(f), indicate how many different electron-domain geometries are consistent with the molecular geometry shown. [Section 9.2]



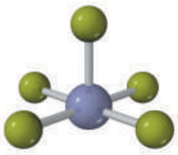
(a)



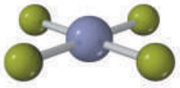
(b)



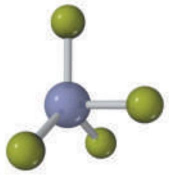
(c)



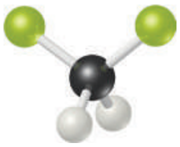
(d)



(e)

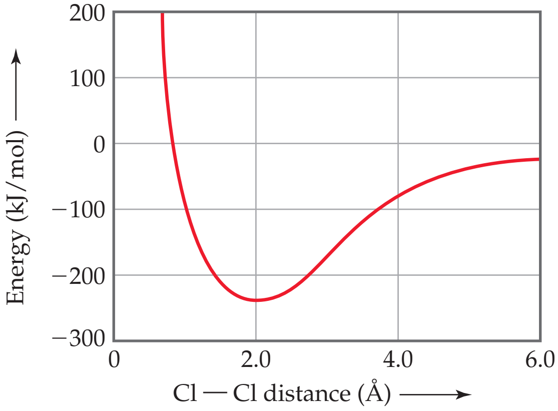


(f)

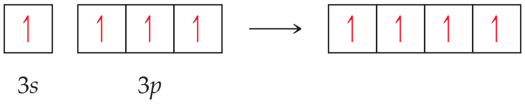


9.4 The molecule shown here is *difluoromethane* (CH_2F_2), which is used as a refrigerant called R-32. (**a**) Based on the structure, how many electron domains surround the C atom in this molecule? (**b**) Would the molecule have a nonzero dipole moment? (**c**) If the molecule is polar, which of the following describes the direction of the overall dipole moment vector in the molecule: (i) from the carbon atom toward a fluorine atom, (ii) from the carbon atom to a point midway between the fluorine atoms, (iii) from the carbon atom to a point midway between the hydrogen atoms, or (iv) from the carbon atom toward a hydrogen atom? [Sections 9.2 and 9.3]

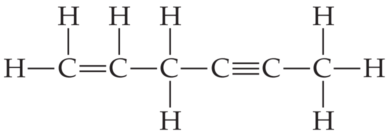
9.5 The following plot shows the potential energy of two Cl atoms as a function of the distance between them. (**a**) If the two atoms are very far away from each other, what is their potential energy of interaction? (**b**) We know that the Cl_2 molecule exists. What is the approximate bond length and bond strength for the Cl—Cl bond in Cl_2 from this graph? (**c**) If the Cl_2 molecule is compressed under higher and higher pressure, does the Cl—Cl bond become stronger or weaker?



9.6 The orbital diagram that follows presents the final step in the formation of hybrid orbitals by a silicon atom. (**a**) Which of the following best describes what took place before the step pictured in the diagram: (i) Two 3*p* electrons became unpaired, (ii) An electron was promoted from the 2*p* orbital to the 3*s* orbital, or (iii) An electron was promoted from the 3*s* orbital to the 3*p* orbital? (**b**) What type of hybrid orbital is produced in this hybridization? [Section 9.5]



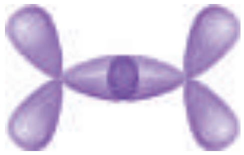
9.7 Consider the following hydrocarbon:

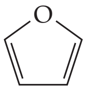


$$H-\overset{H}{C}=\overset{H}{C}-\underset{H}{\overset{H}{C}}-C\equiv C-\underset{H}{\overset{H}{C}}-H$$

(**a**) What is the hybridization at each carbon atom in the molecule? (**b**) How many σ bonds are there in the molecule? (**c**) How many π bonds? (**d**) Identify all the 120° bond angles in the molecule. [Section 9.6]

9.8 The drawing provided shows the overlap of two hybrid orbitals to form a bond in a hydrocarbon. (**a**) Which of the following types of bonds is being formed: (i) C—C σ, (ii) C—C π, or (iii) C—H σ? (**b**) Which of the following could be the identity of the hydrocarbon: (i) CH_4 (ii) C_2H_6 (iii) C_2H_4 or (iv) C_2H_2? [Section 9.6]

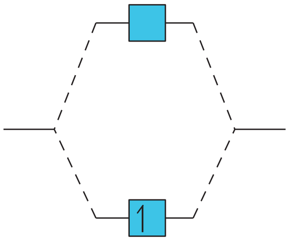




9.9 The molecule shown here is called *furan*. It is represented in the typical shorthand way for organic molecules, with hydrogen atoms not shown, and each of the four vertices representing a carbon atom.

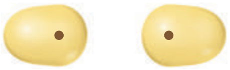
(**a**) What is the molecular formula for furan? (**b**) How many valence electrons are there in the molecule? (**c**) What is the hybridization at each of the carbon atoms? (**d**) How many electrons are in the π system of the molecule? (**e**) The C—C—C bond angles in furan are much smaller than those in benzene. The likely reason is which of the following? (i) The hybridization of the carbon atoms in furan is different from that in benzene. (ii) Furan does not have another resonance structure equivalent to the one shown here. (iii) The atoms are forced to adopt smaller angles in a five-membered ring than in a six-membered ring. [Section 9.5]

9.10 The following is part of a molecular-orbital energy-level diagram for MOs constructed from 1*s* atomic orbitals.

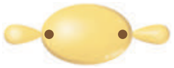


(**a**) What labels do we use for the two MOs shown? (**b**) For which of the following molecules or ions could this be the energy-level diagram: H_2, He_2, H_2^+, He_2^+, or H_2^-?(**c**) What is the bond order of the molecule or ion? (**d**) If an electron is added to the system, into which of the MOs will it be added? [Section 9.7]

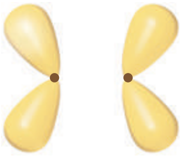
9.11 For each of these contour representations of molecular orbitals, identify (**a**) the atomic orbitals (*s* or *p*) used to construct the MO (**b**) the type of MO (σ or π) (**c**) whether the MO is bonding or antibonding and (**d**) the locations of nodal planes. [Sections 9.7 and 9.8]



(i)

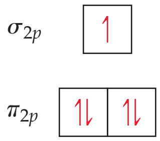


(ii)

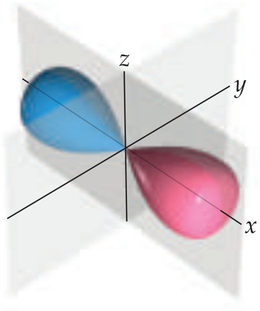


(iii)

9.12 The diagram that follows shows the highest-energy occupied MOs of a neutral molecule CX, where element X is in the same row of the periodic table as C. (**a**) Based on the number of electrons, can you determine the identity of X? (**b**) Would the molecule be diamagnetic or paramagnetic? (**c**) Consider the π_{2p} MOs of the molecule. Would you expect them to have a greater atomic orbital contribution from C, have a greater atomic orbital contribution from X, or be an equal mixture of atomic orbitals from the two atoms? [Section 9.8]

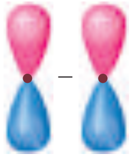


9.13 One of the 2*p* orbitals with phases is shown in the figure. (**a**) Which 2*p* orbital is it? (**b**) Which of the statements about the orbital is or are *true*? (i) The two lobes are equal in size but opposite in sign. (ii) The probability of finding an electron is positive in one direction and negative in the opposite direction. (iii) The phase information for the orbital is lost when the wave function is squared. [Section 9.8]



9.14 The figures show two different possible combinations of two 2*p* atomic orbitals with phases to form a molecular orbital. For each of these figures (**a**) identify whether it represents constructive or destructive addition of the two atomic orbitals, and (**b**) identify whether the resulting molecular orbital will be a σ, σ^*, π, or π^* MO. [Section 9.8]

(i)



(ii)

Molecular Shapes; the VSEPR Model (Sections 9.1 and 9.2)

9.15 An AB_2 molecule that satisfies the octet rule has only A—B single bonds. (**a**) What is the electron-domain geometry of the molecule? (**b**) What is the molecular geometry of the molecule? (**c**) Do all AB_2 molecules that satisfy the octet rule have this same molecular geometry?

9.16 (**a**) Methane (CH_4) and the perchlorate ion (ClO_4^-) are both described as tetrahedral. What does this indicate about their bond angles? (**b**) The NH_3 molecule is trigonal pyramidal, while BF_3 is trigonal planar. Which of these molecules is flat?

9.17 For a particular AB_3 molecule, all the B—A—B bond angles are roughly 109°. (**a**) What is the molecular geometry of the molecule? (**b**) What is the electron-domain geometry of the molecule? (**c**) How many nonbonding electron domains are on the atom A?

9.18 Describe the bond angles to be found in each of the following molecular structures. (**a**) trigonal planar (**b**) tetrahedral (**c**) octahedral (**d**) linear

9.19 (**a**) An AB_6 molecule has no lone pairs of electrons on the A atom. What is its molecular geometry? (**b**) An AB_4 molecule has two lone pairs of electrons on the A atom (in addition to the four B atoms). What is the electron-domain geometry around the A atom? (**c**) For the AB_4 molecule in part (b), predict the molecular geometry.

9.20 Would you expect the nonbonding electron-pair domain in NH_3 to be larger or smaller in size than the corresponding one in PH_3?

9.21 In which of these molecules or ions does the presence of nonbonding electron pairs affect the molecular shape? (**a**) SiH_4 (**b**) PF_3 (**c**) HBr (**d**) HCN (**e**) SO_2

9.22 In which of the following molecules can you confidently predict the bond angles about the central atom, and for which would you be a bit uncertain? Explain in each case. (**a**) H_2S (**b**) BCl_3 (**c**) CH_3I (**d**) CBr_4 (**e**) $TeBr_4$

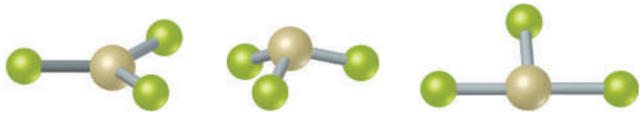
9.23 Give the electron-domain and molecular geometries of a molecule that has the following electron domains on its central atom: (**a**) four bonding domains and no nonbonding domains (**b**) three bonding domains and two nonbonding domains (**c**) five bonding domains and one nonbonding domain (**d**) four bonding domains and two nonbonding domains

9.24 What are the electron-domain and molecular geometries of a molecule that has the following electron domains on its central atom? (**a**) three bonding domains and no nonbonding domains (**b**) three bonding domains and one nonbonding domain (**c**) two bonding domains and two nonbonding domains

9.25 Give the electron-domain and molecular geometries for the following molecules and ions. (**a**) HCN (**b**) SO_3^{2-} (**c**) SF_4 (**d**) PF_6^- (**e**) NH_3Cl^+ (**f**) N_3^-

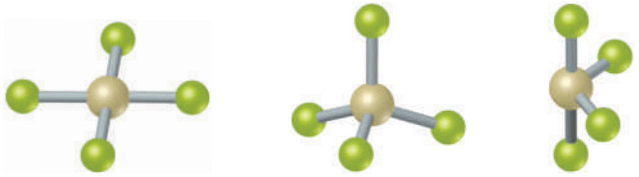
9.26 Draw the Lewis structure for each of the following molecules or ions, and predict their electron-domain and molecular geometries. (**a**) AsF_3 (**b**) CH_3^+ (**c**) BrF_3 (**d**) ClO_3^- (**e**) XeF_2 (**f**) BrO_2^-

9.27 The figure that follows shows ball-and-stick drawings of three possible shapes of an AF_3 molecule. (**a**) For each shape, give the electron-domain geometry on which the molecular geometry is based. (**b**) For each shape, how many nonbonding electron domains are there on atom A? (**c**) Which of the following elements will lead to an AF_3 molecule with the shape in (ii): Li, B, N, Al, P, Cl? (**d**) Name an element A that is expected to lead to the AF_3 structure shown in (iii).



(i) (ii) (iii)

9.28 The figure that follows contains ball-and-stick drawings of three possible shapes of an AF_4 molecule. (**a**) For each shape, give the electron-domain geometry on which the molecular geometry is based. (**b**) For each shape, how many nonbonding electron domains are there on atom A? (**c**) Which of the following elements will lead to an AF_4 molecule with the shape in (iii): Be, C, S, Se, Si, Xe? (**d**) Name an element A that is expected to lead to the AF_4 structure shown in (i).



(i) (ii) (iii)

9.29 Give the approximate values for the indicated bond angles in the following molecules:

(a) 
(b) 
(c) 
(d) 
9.30 Give approximate values for the indicated bond angles in the following molecules:

(a) 
(b) 
(c) 
(d) 
9.31 Ammonia, NH_3, reacts with incredibly strong bases to produce the amide ion, NH_2^-. Ammonia can also react with acids to produce the ammonium ion, NH_4^+. (**a**) Which species (amide ion, ammonia, or ammonium ion) has the largest H—N—H bond angle? (**b**) Which species has the smallest H—N—H bond angle?

9.32 In which of the following AF_n molecules or ions is there more than one F—A—F bond angle: SiF_4, F_5, SF_4,F_3?

9.33 Consider the following XF_4 ions: PF_4^-, BrF_4^-, ClF_4^+, and AlF_4^-. (**a**) Which of the ions have more than an octet of electrons around the central atom? (**b**) For which of the ions will the electron-domain and molecular geometries be the same? (**c**) Which of the ions will have an octahedral electron-domain geometry? (**d**) Which of the ions will exhibit a see-saw molecular geometry?

9.34 Name the proper three-dimensional molecular shapes for each of the following molecules or ions, showing lone pairs as needed: (**a**) ClO_2^- (**b**) SO_4^{2-} (**c**) NF_3 (**d**) CCl_2Br_2 (**e**) SF_4^{2+}

Shapes and Polarity of Polyatomic Molecules (Section 9.3)

9.35 (**a**) Which of the following statements are *true*?

(i) The overall dipole moment of a molecule is the vector sum of its individual bond dipoles.

(ii) If atoms A and B in an AB_n molecule have different electronegativities, then the AB_n molecule must have a nonzero dipole moment.

(iii) The bond dipoles in a tetrahedral AB_4 molecule cancel one another.

(**b**) An AB_2 molecule has a nonzero overall dipole moment. Is its molecular geometry linear or bent?

9.36 Consider a molecule with formula AX_3. Supposing the A—X bond is polar, how would you expect the dipole moment of the AX_3 molecule to change as the X—A—X bond angle increases from 100° to 120°?

9.37 (**a**) Does SCl_2 have a nonzero dipole moment? (**b**) If the answer to part (a) is yes, then which of the following best describes the direction of the net dipole moment? (i) It points along one of the S—Cl bonds with the positive end at the S atom. (ii) It points along one of the S—Cl bonds with the positive end at the Cl atom. (iii) It bisects the Cl—S—Cl angle with the positive end pointing toward the S atom. (iv) It bisects the Cl—S—Cl angle with the positive end pointing away from the S atom.

9.38 (**a**) The PH_3 molecule is polar. Does this offer experimental proof that the molecule cannot be planar? Explain. (**b**) It turns out that ozone, O_3, has a small dipole moment. How is this possible, given that all the atoms are the same?

9.39 (**a**) Is the molecule BF_3 polar or nonpolar? (**b**) If two electrons are added to BF_3 to make the ion BF_3^{2-}, is this ion planar? (**c**) Does the molecule BF_2Cl have a dipole moment?

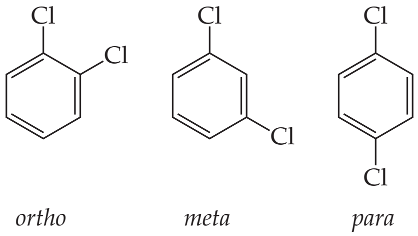
9.40 (**a**) Which of the AF_3 molecules in Exercise 9.27 will have a nonzero dipole moment? (**b**) Which of the AF_4 molecules in Exercise 9.28 will have a zero dipole moment?

9.41 Predict whether each of the following molecules is polar or nonpolar. (**a**) IF (**b**) CS_2 (**c**) SO_3 (**d**) PCl_3 (**e**) SF_6 (**f**) IF_5

9.42 Predict whether each of the following molecules is polar or nonpolar. (**a**) CCl_4 (**b**) NH_3 (**c**) SF_4 (**d**) XeF_4 (**e**) CH_3Br (**f**) GaH_3

9.43 Dichloroethylene ($C_2H_2Cl_2$) has three forms (isomers), each of which is a different substance. (**a**) Draw Lewis structures of the three isomers, all of which have a carbon–carbon double bond. (**b**) Which of these isomers has a zero dipole moment? (**c**) How many isomeric forms can chloroethylene, C_2H_3Cl, have? Would they be expected to have dipole moments?

9.44 Dichlorobenzene, $C_6H_4Cl_2$, exists in three forms (isomers) called *ortho*, *meta*, and *para*:



Which of these has a nonzero dipole moment?

Orbital Overlap; Hybrid Orbitals (Sections 9.4 and 9.5)

9.45 Determine whether each of the following statements is true or false. (**a**) According to valence-bond theory, covalent bonds are made by overlapping orbitals on each atom in the bond. (**b**) A *p* orbital on one atom cannot overlap an *s* orbital on another atom. (**c**) The overlap between the orbitals on two atoms increases as the atoms are pulled apart. (**d**) The potential energy of a molecule increases when the atoms get too close together because of repulsion between the two nuclei. (**e**) The bond distance of a diatomic molecule corresponds to a minimum in the potential energy of the molecule.

9.46 Draw sketches illustrating the overlap between the following orbitals on two atoms: (**a**) the 2*s* orbital on each atom (**b**) the $2p_z$ orbital on each atom (assume both atoms are on the *z* axis) (**c**) the 2*s* orbital on one atom and the $2p_z$ orbital on the other atom.

9.47 For each statement, indicate whether it is true or false. (**a**) The greater the orbital overlap in a bond, the weaker the bond. (**b**) The greater the orbital overlap in a bond, the shorter the bond. (**c**) To create a hybrid orbital, you could use the *s* orbital on one atom with a *p* orbital on another atom. (**d**) Nonbonding electron pairs cannot occupy a hybrid orbital.

9.48 **(a)** According to valence-bond theory, which of the following correctly describes the formation of the Br—Br bond in the Br_2 molecule?

(i) The 4*s* orbital on one atom overlaps with the 4*s* orbital on the other atom.

(ii) The 4*s* orbital on one atom overlaps with a 4*p* orbital on the other atom.

(iii) A 4*p* orbital on one atom overlaps with a 4*p* orbital on the other atom.

(iv) A 4*p* orbital on one atom overlaps with a lone pair on the other atom.

(**b**) According to valence-bond theory, which of the following correctly describes the formation of the H—F bond in the HF molecule?

(i) The electron from the H atom is completely transferred to the F atom.

(ii) The 1*s* orbital of the H atom overlaps with the 1*s* orbital on the F atom.

(iii) The 1*s* orbital on the H atom overlaps with the 2*s* orbital on the F atom.

(iv) The 1*s* orbital on the H atom overlaps with a 2*p* orbital on the F atom.

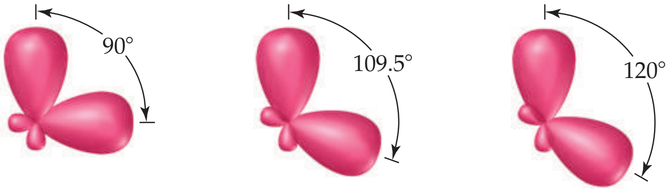
9.49 Consider the molecule BF_3. (**a**) What is the electron configuration of an isolated B atom? (**b**) What is the electron configuration of an isolated F atom? (**c**) What hybrid orbitals should be constructed on the B atom to make the B—F bonds in BF_3? (**d**) What valence orbitals, if any, remain unhybridized on the B atom in BF_3?

9.50 Consider the SCl_2 molecule. (**a**) What is the electron configuration of an isolated S atom? (**b**) What is the electron configuration of an isolated Cl atom? (**c**) What hybrid orbitals should be constructed on the S atom to make the S—Cl bonds in SCl_2? (**d**) What valence orbitals, if any, remain unhybridized on the S atom in SCl_2?

9.51 Indicate the hybridization of the central atom in (**a**) BCl_3, (**b**) $AlCl_4^-$, (**c**) CS_2, (**d**) GeH_4.

9.52 What is the hybridization of the central atom in (**a**) $SiCl_4$, (**b**) HCN, (**c**) SO_3, (**d**) $TeCl_2$?

9.53 Shown here are three pairs of hybrid orbitals, with each set at a characteristic angle. For each pair, determine the type of hybridization, if any, that could lead to hybrid orbitals at the specified angle.



9.54 Determine whether each of the following statements about CH_3^+, CH_3^-, and CH_4 is true or false: (**a**) All three have the same hybridization at the C atom. (**b**) All three have an unhybridized orbital on the C atom. (**c**) The H—C—H angles in CH_3^+ are larger than those in the other two. (**d**) CH_3^- and CH_4 have the same electron-domain geometry.

Multiple Bonds (Section 9.6)

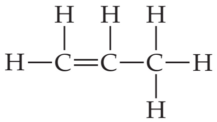
9.55 Which of the following statements are *true*? (**a**) A σ bond is generally stronger than a π bond. (**b**) Two *s* orbitals can make a π bond. (**c**) A π bond is made from the sideways overlap of two *p* orbitals. (**d**) A π bond has two regions of overlap on opposite sides of the internuclear axis.

9.56 (**a**) If the valence atomic orbitals of an atom are *sp* hybridized, how many unhybridized *p* orbitals remain in the valence shell? How many π bonds can the atom form? (**b**) Imagine that you could hold two atoms that are bonded together, twist them, and not change the bond length. Would it be easier to twist (rotate) around a single σ bond or around a double (σ plus π) bond, or would they be the same?

9.57 (**a**) Draw Lewis structures for ethane (C_2H_6), ethylene (C_2H_4), and acetylene (C_2H_2). (**b**) What is the hybridization of the carbon atoms in each molecule? (**c**) Predict which molecules, if any, are planar. (**d**) How many σ and π bonds are there in each molecule?

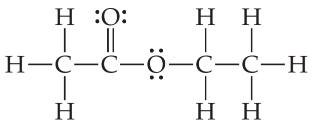
9.58 The nitrogen atoms in N_2 participate in multiple bonding, whereas those in hydrazine, N_2H_4, do not. (**a**) Draw Lewis structures for both molecules. (**b**) What is the hybridization of the nitrogen atoms in each molecule? (**c**) Which molecule has the stronger N—N bond?

9.59 Propylene, C_3H_6, is a gas that is used to form the important polymer called polypropylene. Its Lewis structure is



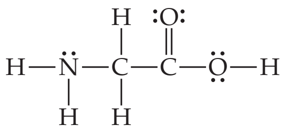
(**a**) What is the total number of valence electrons in the propylene molecule? (**b**) How many valence electrons are used to make σ bonds in the molecule? (**c**) How many valence electrons are used to make π bonds in the molecule? (**d**) How many valence electrons remain in nonbonding pairs in the molecule? (**e**) What is the hybridization at each carbon atom in the molecule?

9.60 Ethyl acetate, $C_4H_8O_2$, is a fragrant substance used both as a solvent and as an aroma enhancer. Its Lewis structure is



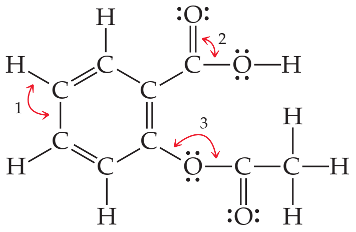
(**a**) What is the hybridization at each of the carbon atoms of the molecule? (**b**) What is the total number of valence electrons in ethyl acetate? (**c**) How many of the valence electrons are used to make σ bonds in the molecule? (**d**) How many valence electrons are used to make π bonds? (**e**) How many valence electrons remain in nonbonding pairs in the molecule?

9.61 Glycine, the simplest amino acid, has the following Lewis structure:



(**a**) What are the approximate bond angles about each of the two carbon atoms, and what are the hybridizations of the orbitals on each of them? (**b**) What are the hybridizations of the orbitals on the two oxygens and the nitrogen atom, and what are the approximate bond angles at the nitrogen? (**c**) What is the total number of σ bonds in the entire molecule, and what is the total number of π bonds?

9.62 Acetylsalicylic acid, better known as aspirin, has the following Lewis structure:



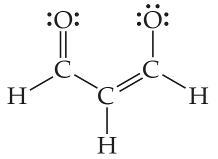
(**a**) What are the approximate values of the bond angles labeled 1, 2, and 3? (**b**) What hybrid orbitals are used about the central atom of each of these angles? (**c**) How many σ bonds are in the molecule?

9.63 Which of the following statements about localized and delocalized π bonding are *true*? (**a**) In a localized π bond, the two electrons in the bond are associated totally with two atoms. (**b**) A molecule or ion that has multiple resonance structures with double bonds exhibits delocalized π bonding. (**c**) In a delocalized π bond, the electrons are spread among three or more atoms. (**d**) Benzene is best described using localized π bonding.

9.64 (**a**) Write a single Lewis structure that satisfies the octet rule for SO_3. (**b**) What is the hybridization at the S atom? (**c**) Are there other equivalent Lewis structures for the molecule? (**d**) Would you expect SO_3 to exhibit delocalized π bonding? (**e**) How many electrons are in the π system of SO_3?

9.65 In the formate ion, HCO_2^-, the carbon atom is the central atom with the other three atoms attached to it. (**a**) Draw a Lewis structure for the formate ion. (**b**) What hybridization is exhibited by the C atom? (**c**) Are there multiple equivalent resonance structures for the ion? (**d**) How many electrons are in the π system of the ion?

9.66 Consider the following Lewis structure:



(**a**) Does the Lewis structure depict a neutral molecule or an ion? If it is an ion, what is the charge on the ion? (**b**) What hybridization is exhibited by each of the carbon atoms? (**c**) Are there multiple equivalent resonance structures for the species? (**d**) How many electrons are in the π system of the species?

9.67 Predict the molecular geometry of each of the following molecules:

(a) $\mathrm{H{-}C{\equiv}C{-}C{\equiv}C{-}C{\equiv}N}$

(b) $\mathrm{H{-}O{-}C({=}O){-}C({=}O){-}O{-}H}$

(c) $\mathrm{H{-}N{=}N{-}H}$

9.68 What hybridization do you expect for the atom indicated in red in each of the following species? (**a**) $CH_3CO_2^-$ (**b**) PH_4^+ (**c**) AlF_3 (**d**) $H_2C{=}CH{-}CH_2^+$

Molecular Orbitals and Period 2 Diatomic Molecules (Sections 9.7 and 9.8)

9.69 Which of the following statements about molecular orbitals are *true*? (**a**) A molecular orbital can hold a maximum of two electrons. (**b**) The number of molecular orbitals formed equals the number of atomic orbitals that are mixed to form the MOs. (**c**) A bonding molecular orbital will have a lower energy than that of the two atomic orbitals that are mixed to make the MO. (**d**) Electrons cannot be put in antibonding molecular orbitals. (**e**) A bonding molecular orbital concentrates electron density in the region between two atoms.

9.70 Which of the following statements about molecular orbitals and hybrid orbitals are *true*? (**a**) Molecular orbitals and hybrid orbitals are both created by mathematically mixing the wave functions of atomic orbitals. (**b**) Molecular orbitals are made by combining atomic orbitals from different atoms. (**c**) Hybrid orbitals and molecular orbitals are different names for the same things. (**d**) A hybrid orbital can hold more electrons than can a molecular orbital.

9.71 Consider the H_2^+ ion. (**a**) Sketch the molecular orbitals of the ion and draw its energy-level diagram. (**b**) How many electrons are there in the H_2^+ ion? (**c**) Write the electron configuration of the ion in terms of its MOs. (**d**) What is the bond order in H_2^+? (**e**) Suppose that the ion is excited by light so that an electron moves from a lower-energy to a higher-energy MO. Would you expect the excited-state H_2^+ ion to be stable or to fall apart? (**f**) Which of the following statements about part (e) is correct: (i) The light excites an electron from a bonding orbital to an antibonding orbital, (ii) The bond order of the ion does not change when an electron is excited, or (iii) In the excited state there are more bonding electrons than antibonding electrons?

9.72 (**a**) Sketch the molecular orbitals of the H_2^- ion and draw its energy-level diagram. (**b**) Write the electron configuration of the ion in terms of its MOs. (**c**) Calculate the bond order in H_2^-. (**d**) Suppose that the ion is excited by light, so that an electron moves from a lower-energy to a higher-energy molecular orbital. Would you expect the excited-state H_2^- ion to be stable? (**e**) Which of the following statements about part (d) is correct: (i) The light excites an electron from a bonding orbital to an antibonding orbital, (ii) The bond order of the ion does not change when an electron is excited, or (iii) In the excited state there are more bonding electrons than antibonding electrons?

9.73 Draw a picture that shows all three 2*p* orbitals on one atom and all three 2*p* orbitals on another atom. (**a**) Imagine the atoms coming close together to bond. How many σ bonds can the two sets of 2*p* orbitals make with each other? (**b**) How many π bonds can the two sets of 2*p* orbitals make with each other? (**c**) How many antibonding orbitals, and of what type, can be made from the two sets of 2*p* orbitals?

9.74 Indicate whether each statement is true or false. (**a**) *s* orbitals can only make σ or σ^* molecular orbitals. (**b**) The probability is 100% for finding an electron at the nucleus in a π^* orbital. (**c**) Antibonding orbitals are higher in energy than bonding orbitals (if all orbitals are created from the same atomic orbitals). (**d**) Electrons cannot occupy an antibonding orbital.

9.75 Consider the valence molecular orbitals for the Na_2 molecule that result from mixing the 3*s* valence atomic orbitals on each of the Na atoms. (**a**) How many molecular orbitals will be formed? (**b**) What is the bond order of the Na_2 molecule? (**c**) What is the bond order of the Na_2^+ molecular ion? (**d**) Which is expected to have the longer Na—Na bond, Na_2 or Na_2^+? (**e**) Which is expected to have the stronger Na—Na bond, Na_2 or Na_2^+?

9.76 (**a**) Based on its molecular-orbital diagram, what is the bond order of the O_2 molecule? (**b**) What is the expected bond order for the *peroxide* ion, O_2^{2-}? (**c**) What is the expected bond order for the *superoxide* ion, O_2^-? (**d**) From shortest to longest, predict the ordering of the bond lengths for O_2, O_2^{2-}, and O_2^-. (**e**) From weakest to strongest, predict the ordering of the bond strengths for O_2, O_2^{2-}, and O_2^-.

9.77 Determine whether each of the following statements about diamagnetism and paramagnetism is true or false: (**a**) A diamagnetic substance is weakly repelled from a magnetic field. (**b**) A substance with unpaired electrons will be diamagnetic. (**c**) A paramagnetic substance is attracted to a magnetic field. (**d**) The O_2 molecule is paramagnetic.

9.78 (**a**) Which of the following is expected to be paramagnetic: Ne, Li_2, Li_2^+, N_2, N_2^+, N_2^{2-}? (**b**) For each of the substances in part (a) that is paramagnetic, determine the number of unpaired electrons it has.

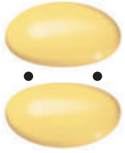
9.79 Using Figures 9.39 and 9.43 as guides, draw the molecular-orbital electron configuration for (**a**) B_2^+, (**b**) Li_2^+, (**c**) N_2^+, (**d**) Ne_2^{2+}. In each case indicate whether the addition of an electron to the ion would increase or decrease the bond order of the species.

9.80 If we assume that the energy-level diagrams for homonuclear diatomic molecules shown in Figure 9.43 can be applied to heteronuclear diatomic molecules and ions, predict the bond order and magnetic behavior of (**a**) CO^+, (**b**) NO^-, (**c**) OF^+, (**d**) NeF^+.

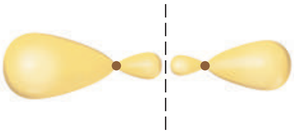
9.81 Determine the electron configurations for CN^+, CN, and CN^-. (**a**) Which species has the strongest C—N bond? (**b**) Which species, if any, is paramagnetic?

9.82 (**a**) The nitric oxide molecule, NO, readily loses one electron to form the NO^+ ion. Which of the following is the best explanation of why this happens? (i) Oxygen is more electronegative than nitrogen. (ii) The highest energy electron in NO lies in a π^*_{2p} molecular orbital. (iii) The π^*_{2p} MO in NO is completely filled. (**b**) Predict the order of the N—O bond strengths in NO, NO^+, and NO^-, and determine whether each is diamagnetic or paramagnetic. (**c**) With what neutral homonuclear diatomic molecules are the NO^+ and NO^- ions isoelectronic (same number of electrons)?

9.83 Assume that the MOs of diatomics from the third row of the periodic table, such as P_2, are analogous to those from the second row. (**a**) Which valence atomic orbitals of P are used to construct the MOs of P_2? (**b**) The figure that follows shows a sketch of one of the MOs for P_2. What is the label for this MO? (**c**) For the P_2 molecule, how many electrons occupy the MO in the figure? (**d**) Is P_2 expected to be diamagnetic or paramagnetic?



9.84 The iodine bromide molecule, IBr, is an *interhalogen compound*. Assume that the molecular orbitals of IBr are analogous to the homonuclear diatomic molecule F_2. (**a**) Which valence atomic orbitals of I and of Br are used to construct the MOs of IBr? (**b**) What is the bond order of the IBr molecule? (**c**) One of the valence MOs of IBr is sketched here. Determine whether each of the following statements about this orbital is *true*: (i) This is an antibonding orbital. (ii) The larger contribution is from the I atom. (iii) The energy of the molecular orbital is closer in energy to the valence atomic orbitals of Br than to those of I. (**d**) What is the label for the MO sketched here? (**e**) For the IBr molecule, how many electrons occupy the MO sketched here?



Additional Exercises

9.85 (**a**) Determine whether each of the following statements about the VSEPR model is *true*:

(i) The model is based on the arrangement of electron domains that minimizes the overall repulsion among them.

(ii) A double bond is considered to be two electron domains.

(iii) A nonbonding electron domain is more spread out in space than a bonding domain.

(**b**) Which of the following statements about the application of the VSEPR model are *true*?

(i) The optimum arrangement of four electron domains is square planar.

(ii) For a trigonal-bipyramidal electron-domain geometry, it is preferable to put nonbonding electron domains in an equatorial position.

(iii) An AB_3 molecule that exhibits a tetrahedral electron-domain geometry has no nonbonding electron domains on atom A.

9.86 An AB_3 molecule is described as having a trigonal-bipyramidal electron-domain geometry. (**a**) How many nonbonding domains are on atom A? (**b**) Based on the information given, which of the following is the molecular geometry of the molecule: (i) trigonal planar (ii) trigonal pyramidal (iii) T-shaped or (iv) tetrahedral?

9.87 Which of the following statements about the PF_4Cl molecule are *true*? (**a**) The molecule has an octahedral electron-domain geometry. (**b**) The P—Cl electron domain is larger than the P—F electron domains. (**c**) The Cl atom will occupy an equatorial site. (**d**) The molecule is hypervalent.

9.88 The vertices of a tetrahedron correspond to four alternating corners of a cube. By using analytical geometry, demonstrate that the angle made by connecting two of the vertices to a point at the center of the cube is 109.5°, the characteristic angle for tetrahedral molecules.

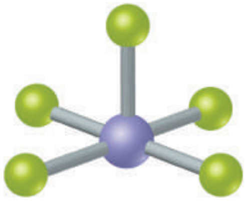
9.89 Fill in the blank spaces in the following chart. If the molecule column is blank, find an example that fulfills the conditions of the rest of the row.

Molecule	Electron-Domain Geometry	Hybridization of Central Atom	Dipole Moment? Yes or No
CO_2			
		sp^3	Yes
		sp^3	No
	Trigonal planar		No
SF_4			
	Octahedral		No
		sp^2	Yes
	Trigonal bipyramidal		No
XeF_2			

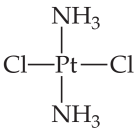
9.90 From their Lewis structures, determine the number of σ and π bonds in each of the following molecules or ions. (**a**) CO_2 (**b**) cyanogen, $(CN)_2$ (**c**) formaldehyde, H_2CO (**d**) formic acid, HCOOH, which has one H and two O atoms attached to C

9.91 The lactic acid molecule, $CH_3CH(OH)COOH$, gives sour milk its unpleasant, sour taste. (**a**) Draw the Lewis structure for the molecule, assuming that carbon always forms four bonds in its stable compounds. (**b**) How many π and how many σ bonds are in the molecule? (**c**) Which CO bond is shortest in the molecule? (**d**) What is the hybridization of atomic orbitals around the carbon atom associated with that short bond? (**e**) What are the approximate bond angles around each carbon atom in the molecule?

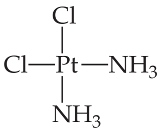
9.92 An AB_5 molecule adopts the geometry shown here. (**a**) What is the name of this molecular geometry? (**b**) What is the electron-domain geometry for the molecule? (**c**) Suppose the B atoms are halogen atoms. Of which group in the periodic table is atom A a member: (i) group 5A (ii) group 6A (iii) group 7A (iv) group 8A, or (v) is more information needed?



9.93 There are two compounds of the formula $Pt(NH_3)_2Cl_2$:



$$\begin{array}{ccc} & NH_3 & \\ & | & \\ Cl— & Pt & —Cl \\ & | & \\ & NH_3 & \end{array}$$



$$\begin{array}{ccc} & Cl & \\ & | & \\ Cl— & Pt & —NH_3 \\ & | & \\ & NH_3 & \end{array}$$

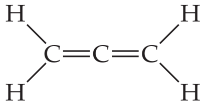
The compound on the right is called *cisplatin*, and the compound on the left is called *transplatin*. (**a**) Which compound has a nonzero dipole moment? (**b**) One of these compounds is an anticancer drug, and one is inactive. The anticancer drug works by its chloride ions undergoing a substitution reaction with nitrogen atoms in DNA that are close together, forming a N—Pt—N angle of about 90°. Which compound would you predict to be the anticancer drug?

9.94 The O—H bond lengths in the water molecule (H_2O) are 0.96 Å, and the H—O—H angle is 104.5°. The overall dipole moment of the water molecule is 1.85 D. (**a**) Determine whether each of the following statements about the bond dipoles and the overall dipole moment of H_2O is true: (i) The negative ends of the bond dipoles both point at the O atom. (ii) The two bond dipoles point in different directions. (iii) The overall dipole moment points in the same direction as one of the bond dipoles. (**b**) Calculate the magnitude of the bond dipole of the O—H bonds. (Note: You will need to use vector addition to do this.) (**c**) Compare your answer from part (b) to the dipole moments of the hydrogen halides (Table 8.3). Is your answer in accord with the relative electronegativity of oxygen?

9.95 (**a**) Predict the electron-domain geometry around the central Xe atom in XeF_2, XeF_4, and XeF_6. (**b**) The molecule IF_7 has a pentagonal bipyramid structure: five fluorines are equatorial, forming a flat pentagon around the central iodine atom, and the other two fluorines are axial. Predict the molecular geometry of IF_6^-.

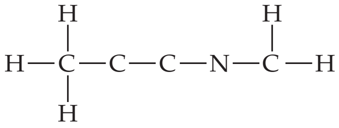
9.96 Which of the following statements about hybrid orbitals is or are *true*? (**a**) After an atom undergoes *sp* hybridization, there is one unhybridized *p* orbital on the atom, (**b**) Under sp^2 hybridization, the large lobes point to the vertices of an equilateral triangle, and (**c**) The angle between the large lobes of sp^3 hybrids is 109.5°.

9.97 The Lewis structure for allene is



Make a sketch of the structure of this molecule that is analogous to Figure 9.22. In addition, answer the following questions: (**a**) What is the hybridization at the central C atom? (**b**) Is the molecule planar? (**c**) Does it have a nonzero dipole moment? (**d**) Would the π bonding in allene be described as delocalized?

9.98 The molecule C_4H_5N has the connectivity shown here. (**a**) After the Lewis structure for the molecule is completed, how many σ and how many π bonds are there in this molecule? (**b**) How many atoms in the molecule exhibit (i) *sp* hybridization (ii) sp^2 hybridization and (iii) sp^3 hybridization?



$$\begin{array}{ccccccccccccc} & & H & & & & & & & & H & & \\ & & | & & & & & & & & | & & \\ H & — & C & — & C & — & C & — & N & — & C & — & H \\ & & | & & & & & & & & & & \\ & & H & & & & & & & & & & \end{array}$$

9.99 Sodium azide is a shock-sensitive compound that releases N_2 upon physical impact. The compound is used in automobile airbags. The azide ion is N_3^-. (**a**) Draw the Lewis structure of the azide ion that minimizes formal charge (it does not form a triangle). Is it linear or bent? (**b**) State the hybridization of the central N atom in the azide ion. (**c**) How many σ bonds and how many π bonds does the central nitrogen atom make in the azide ion?

9.100 In ozone, O_3, the two oxygen atoms on the ends of the molecule are equivalent to one another. (**a**) What is the best choice of hybridization scheme for the atoms of ozone? (**b**) For one of the resonance forms of ozone, which of the orbitals are used to make bonds and which are used to hold nonbonding pairs of electrons? (**c**) Which of the orbitals can be used to delocalize the π electrons? (**d**) How many electrons are delocalized in the π system of ozone?

9.101 Butadiene, C_4H_6, is a planar molecule that has the following carbon–carbon bond lengths:

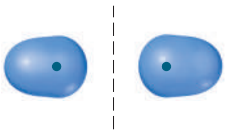
$$H_2C\underset{1.34\ \text{Å}}{=\!=\!=}CH\underset{1.48\ \text{Å}}{———}CH\underset{1.34\ \text{Å}}{=\!=\!=}CH_2$$

(**a**) Predict the bond angles around each of the carbon atoms and sketch the molecule. (**b**) From left to right, what is the hybridization of each carbon atom in butadiene? (**c**) The middle C—C bond length in butadiene (1.48 Å) is a little shorter than the average C—C single bond length (1.54 Å). Does this imply that the middle C—C bond in butadiene is weaker or stronger than the average C—C single bond? (**d**) Based on your answer for part (c), discuss what additional aspects of bonding in butadiene might support the shorter middle C—C bond.

9.102 The structure of *borazine*, $B_3N_3H_6$, is a six-membered ring of alternating B and N atoms. There is one H atom bonded to each B and to each N atom. The molecule is planar. (**a**) Write a Lewis structure for borazine in which the formal charge on every atom is zero. (**b**) Write a Lewis structure for borazine in which the octet rule is satisfied for every atom. (**c**) What are the formal charges on the atoms in the Lewis structure from part (b)? Given the electronegativities of B and N, do the formal charges seem favorable or unfavorable? (**d**) Do either of the Lewis structures in parts (a) and (b) have multiple resonance structures? (**e**) What are the hybridizations at the B and N atoms in the Lewis structures from parts (a) and (b)? Would you expect the molecule to be planar for both Lewis structures? (**f**) The six B—N bonds in the borazine molecule are all identical in length at 1.44 Å. Typical values for the bond lengths of B—N single and double bonds are 1.51 Å and 1.31 Å, respectively. Does the value of the B—N bond length seem to favor one Lewis structure over the other? (**g**) How many electrons are in the π system of borazine?

9.103 The highest occupied molecular orbital of a molecule is abbreviated as the HOMO. The lowest unoccupied molecular orbital in a molecule is called the LUMO. Experimentally, you can measure the difference in energy between the HOMO and LUMO by taking the electronic absorption (UV–visible) spectrum of the molecule. Peaks in the electronic absorption spectrum can be labeled as π_{2p}–π_{2p}^*, σ_{2s}–σ_{2s}^*, and so on, corresponding to electrons being promoted from one orbital to another. The HOMO–LUMO transition corresponds to molecules going from their ground state to their first excited state. (**a**) Write out the molecular-orbital valence electron configurations for the ground state and first excited state for N_2. (**b**) Is N_2 paramagnetic or diamagnetic in its first excited state? (**c**) The electronic absorption spectrum of the N_2 molecule has the lowest energy peak at 170 nm. To what orbital transition does this correspond? (**d**) Calculate the energy of the HOMO–LUMO transition in part (a) in terms of kJ/mol. (**e**) Is the N—N bond in the first excited state stronger or weaker compared to that in the ground state?

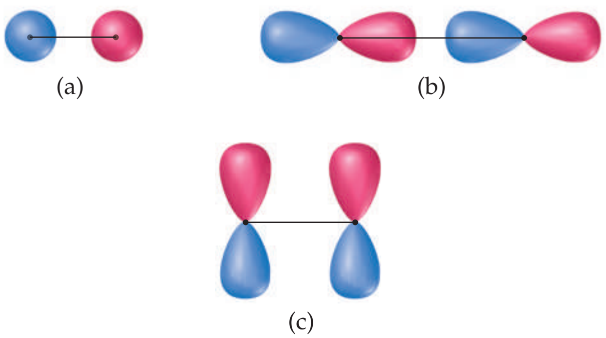
9.104 One of the molecular orbitals of the H_2^- ion can be sketched as follows:



(**a**) Is the molecular orbital a σ or π MO? Is it bonding or antibonding? (**b**) In H_2^-, how many electrons occupy the MO sketched here? (**c**) What is the bond order in the H_2^- ion? (**d**) Compared to the H—H bond in H_2, the H—H bond in H_2^- is expected to be which of the following? (i) shorter and stronger (ii) longer and stronger (iii) shorter and weaker (iv) longer and weaker or (v) the same length and strength

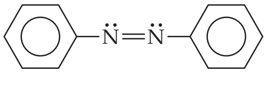
9.105 Place the following molecules and ions in order from smallest to largest bond order: H_2^+, B_2, N_2^+, F_2^+, and Ne_2.

9.106 The following sketches show the atomic orbital wave functions (with phases) used to construct some of the MOs of a homonuclear diatomic molecule. For each sketch, determine the type of MO that will result from mixing the atomic orbital wave functions as drawn. Use the same labels for the MOs as in the "Closer Look" box on phases.

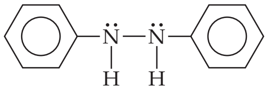


(a) (b) (c)

9.107 *Azo dyes* are organic dyes that are used for many applications, such as the coloring of fabrics. Many azo dyes are derivatives of the organic substance *azobenzene,* $C_{12}H_{10}N_2$. A closely related substance is *hydrazobenzene,* $C_{12}H_{12}N_2$. The Lewis structures of these two substances are



Azobenzene



Hydrazobenzene

(Recall the shorthand notation used for benzene.) (**a**) What is the hybridization at the N atom in each of the substances? (**b**) How many unhybridized atomic orbitals are there on the N and the C atoms in each of the substances? (**c**) Predict the N—N—C angles in each of the substances. (**d**) Azobenzene is said to have greater delocalization of its π electrons than hydrazobenzene. Discuss this statement in light of your answers to (a) and (b). (**e**) All the atoms of azobenzene lie in one plane, whereas those of hydrazobenzene do not. Is this observation consistent with the statement in part (d)? (**f**) Azobenzene is an intense red-orange color, whereas hydrazobenzene is nearly colorless. Which molecule would be a better one to use in a solar energy conversion device? (See the "Chemistry and Sustainability" box for more information about solar cells.)

9.108 Carbon monoxide, CO, is isoelectronic to N_2. (**a**) Draw a Lewis structure for CO that satisfies the octet rule. (**b**) Assume that the diagram in Figure 9.46 can be used to describe the MOs of CO. What is the predicted bond order for CO? Is this answer in accord with the Lewis structure you drew in part (a)? (**c**) Experimentally, it is found that the highest-energy electrons in CO reside in a σ-type MO. Which of the following statements best explains this observation? (i) The observation is consistent with the ordering of MOs in Figure 9.46. (ii) The observation suggests that the ordering of the π_{2p} and π_{2p}^* MOs needs to be modified compared to Figure 9.46. (iii) The observation suggests that the σ_{2p} MO in Figure 9.46 is pushed above the π_{2p} MO by mixing similar to that in Figure 9.42. (**d**) Would you expect the π_{2p} MOs of CO to have equal atomic orbital contributions from the C and O atoms? If not, which atom would have the greater contribution?

9.109 The energy-level diagram in Figure 9.40 shows that the sideways overlap of a pair of *p* orbitals produces two molecular orbitals, one bonding and one antibonding. In ethylene there is a pair of electrons in the bonding π orbital between the two carbons. Absorption of a photon of the appropriate wavelength can result in promotion of one of the bonding electrons from the π_{2p} to the π_{2p}^* molecular orbital. (**a**) Assuming this electronic transition corresponds to the HOMO–LUMO transition, what is the HOMO in ethylene? (**b**) Assuming this electronic transition corresponds to the HOMO–LUMO transition, what is the LUMO in ethylene? (**c**) Is the C—C bond in ethylene stronger or weaker in the excited state than in the ground state? Why? (**d**) Is the C—C bond in ethylene easier to twist in the ground state or in the excited state?

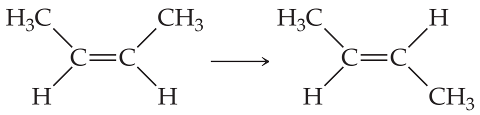
9.110 A compound composed of 2.1% H, 29.8% N, and 68.1% O has a molar mass of approximately 50 g/mol. (**a**) What is the molecular formula of the compound? (**b**) What is its Lewis structure if H is bonded to O? (**c**) What is the geometry of the molecule? (**d**) What is the hybridization of the orbitals around the N atom? (**e**) How many σ and how many π bonds are there in the molecule?

9.111 Sulfur tetrafluoride (SF_4) reacts slowly with O_2 to form sulfur tetrafluoride monoxide (OSF_4) according to the following unbalanced reaction:

$$SF_4(g) + O_2(g) \longrightarrow OSF_4(g)$$

The O atom and the four F atoms in OSF_4 are bonded to a central S atom. (**a**) Balance the equation. (**b**) Write a Lewis structure of OSF_4 in which the formal charges of all atoms are zero. (**c**) Use average bond enthalpies (Table 8.3) to estimate the enthalpy of the reaction. Is it endothermic or exothermic? (**d**) Determine the electron-domain geometry of OSF_4, and write two possible molecular geometries for the molecule based on this electron-domain geometry. (**e**) For each of the molecules you drew in part (d), state how many fluorine atoms are equatorial and how many are axial.

9.112 The molecule 2-butene, C_4H_8, can undergo a geometric change called *cis–trans isomerization*:



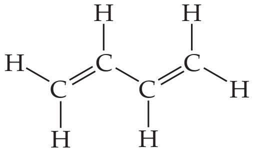
cis-2-butene *trans*-2-butene

As discussed in the "Chemistry and Life" box on the chemistry of vision, such transformations can be induced by light and are the key to human vision. (**a**) What is the hybridization at the two central carbon atoms of 2-butene? (**b**) The isomerization occurs by rotation about the central C—C bond. With reference to Figure 9.29, which of the following statements best characterizes what happens halfway through the rotation from *cis*- to *trans*-2-butene? (i) The σ bond between the two C atoms is destroyed. (ii) The π bond between the two C atoms is destroyed. (iii) Neither the σ bond nor the π bond between the two C atoms is destroyed. (**c**) Based on average bond enthalpies (Table 8.3), how much energy per molecule must be supplied to break the C—C π bond? (**d**) What is the longest wavelength of light that will provide photons of sufficient energy to break the C—C π bond and cause the isomerization? (**e**) Is the wavelength in your answer to part (d) in the visible portion of the electromagnetic spectrum? (**f**) Based on your answer to part (e), could this isomerization reaction be the basis for human vision?

9.113 Methyl isocyanate, CH_3NCO, was made infamous in 1984 when an accidental leakage of this compound from a storage tank in Bhopal, India, resulted in the deaths of about 3800 people and severe and lasting injury to many thousands more. (**a**) Draw a Lewis structure for methyl isocyanate. (**b**) Draw a ball-and-stick model of the structure, including estimates of all the bond angles in the compound. (**c**) Predict all the bond distances in the molecule. (**d**) Do you predict that the molecule will have a dipole moment?

Design an Experiment

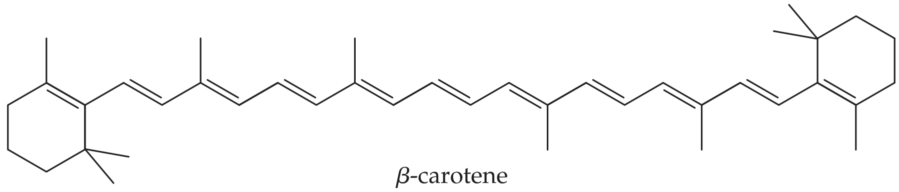
In this chapter we have been introduced to a number of new concepts, including the delocalization of π systems of molecules and the molecular-orbital description of molecular bonding. A connection between these concepts is provided by the field of *organic dyes*, molecules with delocalized π systems that have color. The color is due to the excitation of an electron from the *highest occupied molecular orbital* (HOMO) to the *lowest unoccupied molecular orbital* (LUMO). It is hypothesized that the energy gap between the HOMO and the LUMO depends on the length of the π system. Imagine that you are given samples of the following substances to test this hypothesis:



or, in shorthand notation for organic molecules

butadiene

hexatriene



β-carotene

β-Carotene is the substance chiefly responsible for the bright orange color of carrots. It is also an important nutrient for the body's production of retinal (see the "Chemistry and Life" box in Section 9.6). (**a**) What experiments could you design to determine the amount of energy needed to excite an electron from the HOMO to the LUMO in each of these molecules? (**b**) How might you graph your data to determine whether a relationship exists between the length of the π system and the excitation energy? (**c**) What additional molecules might you want to procure to further test the ideas developed here? (**d**) How could you design an experiment to determine whether the delocalized π systems and not some other molecular features, such as molecular length or the presence of π bonds, are important in making the excitations occur in the visible portion of the spectrum? (*Hint:* You might want to test some additional molecules not shown here.)

10

GASES

▲ Hot air is less dense than cool air, so balloons filled with hot air will rise.

In this chapter, we examine the physical properties of gases. Because gases are the simplest state of matter, they serve as an excellent starting point for probing the behavior of large collections of atoms or molecules. Indeed, it is fairly straightforward to formulate a simple model for gases that explains their behavior under most common conditions. We gain further insight by then comparing how real gases differ from this ideal model as conditions change. Thus, while we start with a description that treats all gases the same regardless of their chemical identity, we end by gaining an understanding of important aspects of the physical behavior of molecules.

WHAT'S AHEAD

10.1 ▶ **Physical Characteristics of Gases** Compare the distinguishing characteristics of gases with those of liquids and solids. Describe gas *pressure* and the units used to express it, and consider Earth's atmosphere and the pressure it exerts.

10.2 ▶ **The Gas Laws** Express the state of a gas in terms of its volume, pressure, temperature, and quantity, and examine several *gas laws*, which are empirical relationships among these four variables.

10.3 ▶ **The Ideal-Gas Equation** Examine the assumptions behind the ideal-gas equation, which combines the gas laws of the previous section into a single equation, $PV = nRT$, and use this equation to analyze the properties of gases.

10.4 ▶ **Gas Mixtures and Partial Pressures** Recognize and use the fact that in a mixture of gases, each gas exerts a pressure that is part of the total pressure. This *partial pressure* is the pressure the gas would exert if it were by itself.

10.5 ▶ **The Kinetic-Molecular Theory of Gases** Relate the macroscopic properties of gases to their behavior at the molecular level. The atoms or molecules that make up a gas are in constant random motion and move with an average kinetic energy that is proportional to the temperature of the gas.

10.6 ▶ **Molecular Speeds, Effusion, and Diffusion** Use kinetic-molecular theory to calculate the speed of gas molecules and predict relative rates of *effusion* and *diffusion*.

10.7 ▶ **Real Gases: Deviations from Ideal Behavior** Examine the reasons why real gases deviate from ideal behavior and the conditions where those deviations are significant. The *van der Waals equation* accounts for real gas behavior at high pressures and low temperatures.

10.1 | Physical Characteristics of Gases

Learning Objectives

When you have finished Section 10.1, you should be able to:

- Describe how the properties of gases differ from those of solids and liquids.
- Define gas pressure and determine it from experimental data.
- Interconvert between units of pressure.

Of the few elements that exist as gases at ordinary temperatures and pressures, He, Ne, Ar, Kr, and Xe are monatomic and H_2, N_2, O_2, F_2, and Cl_2 are diatomic. Many molecular compounds are gases under ordinary conditions, and **Table 10.1** lists a few of them. All of these gases are composed entirely of nonmetallic elements. Furthermore, all have simple molecular formulas and, therefore, low molar masses.

Substances that are liquids or solids under ordinary conditions can also exist in the gaseous state, where they are often referred to as **vapors**. The substance H_2O, for example, can exist as liquid water, solid ice, or water vapor.

Even though different gaseous substances may have very different *chemical* properties, they behave quite similarly as far as their *physical* properties are concerned. For example, the N_2 and O_2 that account for approximately 99% of our atmosphere have very different chemical properties—O_2 supports human life but N_2 does not, to name just one difference—but these two components of air behave physically as one gaseous material because their physical properties are essentially identical.

The physical properties of gases differ significantly from those of solids and liquids. For example, a gas expands spontaneously to fill its container. Consequently, the volume of a gas equals the volume of its container. Gases also are highly compressible: When pressure is applied to a gas, its volume readily decreases. Solids and liquids, on the other hand, do not expand to fill their containers and are not readily compressible.

Two or more gases form a homogeneous mixture regardless of the identities or relative proportions of the gases; the atmosphere serves as an excellent example. Two or more liquids or two or more solids may or may not form homogeneous mixtures, depending on their chemical nature. For example, when water and gasoline are mixed, the two liquids remain as separate layers. In contrast, the water vapor and gasoline vapors above the liquids form a homogeneous gas mixture.

The characteristic properties of gases—expanding to fill a container, being highly compressible, forming homogeneous mixtures—arise because the molecules are relatively far apart. In any given volume of air, for example, the molecules take up only about 0.1% of the total volume, with the rest being empty space. Thus, each molecule behaves largely as though the others were not present. As a result, different gases behave similarly even though they are made up of different molecules.

Pressure

One characteristic of gases is that they all exert a *pressure* on any surface with which they are in contact. We can interpret this observation in terms of the atoms or molecules in the gas. The molecules of a gas move chaotically, colliding with each other and with the walls of their container. The impacts with the container walls exert a force—an

TABLE 10.1 Some Common Compounds That Are Gases at Room Temperature

Formula	Name	Characteristics
HCN	Hydrogen cyanide	Very toxic, slight odor of bitter almonds
H_2S	Hydrogen sulfide	Very toxic, odor of rotten eggs
CO	Carbon monoxide	Toxic, colorless, odorless
CO_2	Carbon dioxide	Colorless, odorless
CH_4	Methane	Colorless, odorless, flammable
C_2H_4	Ethene (ethylene)	Colorless, ripens fruit
C_3H_8	Propane	Colorless, odorless, bottled gas
N_2O	Nitrous oxide	Colorless, sweet odor, laughing gas
NO_2	Nitrogen dioxide	Toxic, red-brown, irritating odor
NH_3	Ammonia	Colorless, pungent odor
SO_2	Sulfur dioxide	Colorless, irritating odor

outward push against the walls. The **pressure**, P, that a gas exerts is defined as the force, F, divided by the area, A, of the surface on which the force is acting:

$$P = \frac{F}{A} \qquad [10.1]$$

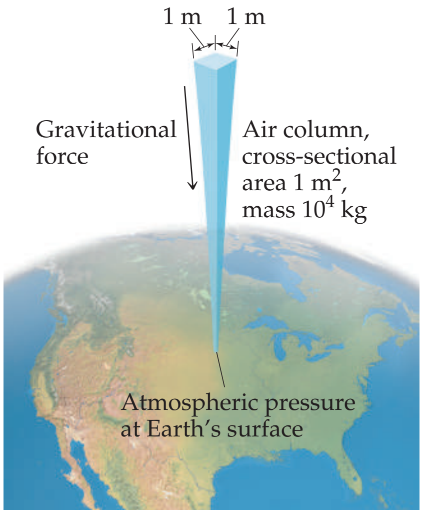
Atmospheric Pressure and the Barometer

People, apples, and nitrogen molecules all experience an attractive gravitational force that pulls them toward the center of Earth. When an apple comes loose from a tree, for example, this force causes the apple to be accelerated toward Earth, its speed increasing as its potential energy is converted into kinetic energy. (Section 1.4) The gas atoms and molecules of the atmosphere also experience a gravitational acceleration. Because these particles have such tiny masses, however, their thermal energies of motion (their kinetic energies) override the gravitational forces, so the particles that make up the atmosphere don't pile up at Earth's surface. Nevertheless, the gravitational force does operate, and it causes the atmosphere as a whole to press down on Earth's surface, creating *atmospheric pressure*, defined as the force exerted by the atmosphere on a given surface area.

You can demonstrate the existence of atmospheric pressure with an empty plastic water bottle. If you suck on the mouth of the empty bottle, chances are you can cause the bottle to partially cave in. When you break the partial vacuum you have created, the bottle pops out to its original shape. The bottle caves in because, once you've sucked out some of the air molecules, the air molecules in the atmosphere exert a force on the outside of the bottle that is greater than the force exerted by the lesser number of air molecules inside the bottle.

We can calculate the magnitude of the atmospheric pressure using Equation 10.1. The force, F, exerted by any object is the product of its mass, m, and its acceleration, a: $F = ma$. When applied to our atmosphere, the force is the gravitational force, which is also commonly called weight. The acceleration is that due to gravity, $g = 9.8\ \text{m/s}^2$. Thus, the gravitational force of the atmosphere on Earth's surface (the weight of the atmosphere) is given by $F = mg$.

Now imagine a column of air, 1 m^2 in cross section, extending through the entire atmosphere (**Figure 10.1**). That column has a mass of roughly 10,000 kg. The downward gravitational force exerted on this column is



1 m
1 m
Gravitational force
Air column, cross-sectional area 1 m^2, mass 10^4 kg
Atmospheric pressure at Earth's surface

▲ **Figure 10.1 A calculation of atmospheric pressure.**

$$F = (10{,}000\ \text{kg})(9.8\ \text{m/s}^2) = 1 \times 10^5\ \text{kg-m/s}^2 = 1 \times 10^5\ \text{N}$$

where N is the abbreviation for *newton*, the SI unit for force: $1\ \text{N} = 1\ \text{kg-m/s}^2$.

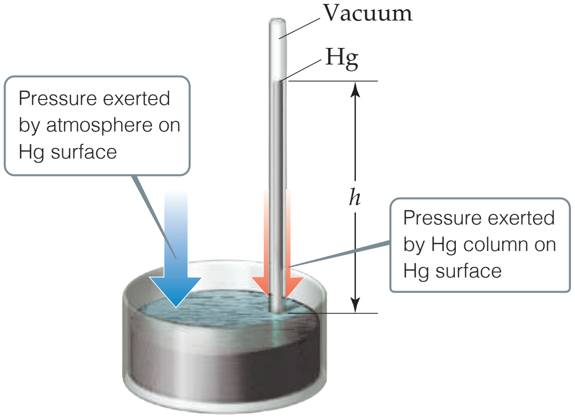
The pressure exerted by the column is this force divided by the cross-sectional area, A, over which the force is applied. Because our air column has a cross-sectional area of 1 m^2, we have for the magnitude of atmospheric pressure at sea level

$$P = \frac{F}{A} = \frac{1 \times 10^5\ \text{N}}{1\ \text{m}^2} = 1 \times 10^5\ \text{N/m}^2 = 1 \times 10^5\ \text{Pa} = 1 \times 10^2\ \text{kPa}$$

The SI unit of pressure is the **pascal** (Pa), named for Blaise Pascal (1623–1662), a French scientist who studied pressure: $1\ \text{Pa} = 1\ \text{N/m}^2$. A related pressure unit is the **bar:** $1\ \text{bar} = 10^5\ \text{Pa} = 10^5\ \text{N/m}^2$. Thus, the atmospheric pressure at sea level we just calculated, 100 kPa, can be reported as 1 bar. (The actual atmospheric pressure at any location depends on weather conditions and altitude.) Another pressure unit is pounds per square inch (psi, lbs/in.^2). At sea level, atmospheric pressure is 14.7 psi.

In the seventeenth century, many scientists and philosophers believed that the atmosphere had no weight. Evangelista Torricelli (1608–1647), a student of Galileo's, proved this untrue. He invented the *barometer* (**Figure 10.2**), which is made from a glass tube more than 760 mm long that is closed at one end, completely filled with mercury, and inverted into a dish of mercury. (Care must be taken so that no air gets into the tube.) When the tube is inverted into the dish, some of the mercury flows out of the tube, but a column of mercury remains in the tube. Torricelli argued that the mercury surface in the dish experiences the full force of Earth's atmosphere, which pushes the mercury up the tube until the pressure exerted by the mercury column downward, due to gravity, equals the atmospheric pressure at the base of the tube. Therefore, *the height,* h, *of the mercury column is a measure of atmospheric pressure and changes as atmospheric pressure changes.*

Go Figure What happens to *h*, the height of the mercury column, if the atmospheric pressure increases?



Vacuum
Hg
Pressure exerted by atmosphere on Hg surface
h
Pressure exerted by Hg column on Hg surface

▲ **Figure 10.2 A mercury barometer.**

Standard atmospheric pressure, which corresponds to the typical pressure at sea level, is the pressure sufficient to support a column of mercury 760 mm high. In SI units, this pressure is 1.01325×10^5 Pa. Standard atmospheric pressure defines some common non-SI units used to express gas pressure, such as the **atmosphere** (atm) and the *millimeter of mercury* (mm Hg). The latter unit is also called the **torr**, after Torricelli: 1 torr = 1 mm Hg. Thus, we have

$$1 \text{ atm} = 760. \text{ mm Hg} = 760. \text{ torr} = 1.01325 \times 10^5 \text{ Pa} = 101.325 \text{ kPa} = 1.01325 \text{ bar}$$

We express gas pressure in a variety of units throughout this chapter, so you should become comfortable converting pressures from one unit to another.

Sample Exercise 10.1

Calculating Pressure

What is the pressure, in kilopascals, on the body of a diver if she is 31.0 m below the surface of the water when the atmospheric pressure on the surface is 98 kPa? Assume that the density of the water is $1.00 \text{ g/cm}^3 = 1.00 \times 10^3 \text{ kg/m}^3$. The gravitational constant is 9.81 m/s^2, and $1 \text{ Pa} = 1 \text{ kg/m-s}^2$.

SOLUTION

Analyze We are asked to calculate the pressure on the diver given the atmospheric pressure (98 KPa) and the depth of the water (31.0 m).

Plan The total pressure on the diver equals that of the atmosphere plus that of the water. The pressure of the water can be calculated starting with Equation 10.1, $P = F/A$. The force, F, due to the water above the diver is given by its mass times the acceleration due to gravity, $F = mg$, where $g = 9.81 \text{ m/s}^2$.

Solve The pressure caused by the water is

$$P = \frac{F}{A} = \frac{mg}{A}$$

The mass of the water is related to its density ($d = m/V$, so $m = d \times V$). We can treat the water as a column whose volume equals its cross-sectional area times its height: $V = A \times h$. When we make these substitutions for mass ($m = d \times V$) and volume ($V = A \times h$), we have

$$P = \frac{mg}{A} = \frac{dVg}{A} = \frac{d(\cancel{A}h)g}{\cancel{A}} = dhg$$

Inserting SI quantities, we have

$$P = dhg = (1.00 \times 10^3 \text{ kg}/m^{\cancel{3}})(31.0 \cancel{\text{m}})(9.81 \cancel{\text{m}}/\text{s}^2)$$

$$= 3.00 \times 10^5 \frac{\text{kg}}{\text{m-s}^2} = 3.00 \times 10^5 \text{ Pa}$$

Thus, the total pressure on the diver is

$$P_{\text{total}} = 98 \text{ kPa} + 300 \text{ kPa} = 398 \text{ kPa}$$

This corresponds to a pressure of 3.94 atm.

▶ **Practice Exercise**

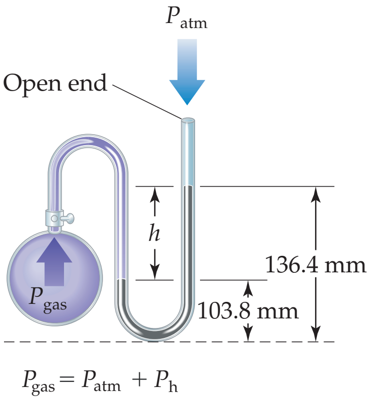
Gallium melts just above room temperature and is liquid over a very wide temperature range (30–2204 °C), which means it would be a suitable fluid for a high-temperature barometer. Given its density, $d_{\text{Ga}} = 6.0 \text{ g/cm}^3$, what would be the height of the column if gallium is used as the barometer fluid and the external pressure is 9.5×10^4 Pa?

We use various devices to measure the pressures of enclosed gases. Tire gauges, for example, measure the pressure of air in automobile and bicycle tires. In laboratories, we sometimes use a *manometer*, which operates on a principle similar to that of a barometer, as shown in Sample Exercise 10.2.

Sample Exercise 10.2

Using a Manometer to Measure Gas Pressure

On a certain day, a laboratory barometer indicates that the atmospheric pressure is 764.7 torr. A sample of gas is placed in a flask attached to an open-end mercury manometer (**Figure 10.3**), and a meter stick is used to measure the height of the mercury in the two arms of the U tube. The height of the mercury in the open-ended arm is 136.4 mm, and the height in the arm in contact with the gas in the flask is 103.8 mm. What is the pressure of the gas in the flask (**a**) in atmospheres, (**b**) in kilopascals?



▲ **Figure 10.3 A mercury manometer.**

SOLUTION

Analyze We are given the atmospheric pressure (764.7 torr) and the mercury heights in the two arms of the manometer, and we are asked to determine the gas pressure in the flask. Recall that millimeters of mercury is a pressure unit. We know that the gas pressure from the flask must be greater than atmospheric pressure because the mercury level in the arm on the flask side (103.8 mm) is lower than the level in the arm open to the atmosphere (136.4 mm). Therefore, the gas from the flask is pushing mercury from the arm in contact with the flask into the arm open to the atmosphere.

Plan We will use the difference in height between the two arms (h in Figure 10.3) to obtain the amount by which the pressure of the gas exceeds atmospheric pressure. Because an open-end mercury manometer is used, the height difference directly measures the pressure difference in mm Hg or torr between the gas and the atmosphere.

Solve

(**a**) The pressure of the gas equals the atmospheric pressure plus h:

$$\begin{aligned} P_{gas} &= P_{atm} + h \\ &= 764.7\ \text{torr} + (136.4\ \text{torr} - 103.8\ \text{torr}) \\ &= 797.3\ \text{torr} \end{aligned}$$

We convert the pressure of the gas to atmospheres:

$$P_{gas} = (797.3\ \cancel{\text{torr}})\left(\frac{1\ \text{atm}}{760\ \cancel{\text{torr}}}\right) = 1.049\ \text{atm}$$

(**b**) To calculate the pressure in kPa, we employ the conversion factor between atmospheres and kPa:

$$1.049\ \cancel{\text{atm}}\left(\frac{101.3\ \text{kPa}}{1\ \cancel{\text{atm}}}\right) = 106.3\ \text{kPa}$$

Check The calculated pressure is a bit more than 1 atm, which is about 101 kPa. This makes sense because we anticipated that the pressure in the flask would be greater than the atmospheric pressure (764.7 torr = 1.01 atm) acting on the manometer.

▶ Practice Exercise

If the pressure of the gas inside the flask were increased and the height of the column in the open-ended arm went up by 5.0 mm in Figure 10.3, what would be the new pressure of the gas in the flask, in torr?

Self-Assessment Exercises

SAE 10.1 Which of the following statements is *false*? (**a**) Many physical properties of gases are similar to one another. (**b**) Gases are much more compressible than liquids and solids. (**c**) Given enough time, any mixture of gases will form a homogeneous mixture. (**d**) Many chemical properties of gases are similar to one another.

SAE 10.2 The atmosphere of Venus is made up mostly of CO_2. The temperature and pressure at the surface of the planet are estimated to be 740 K and 93 bar, respectively. What is the mass of a 1.0 m^2 cross-sectional column of Venus's atmosphere that extends from the surface to the upper reaches of the atmosphere? The acceleration due to gravity on Venus is 8.9 m/s^2. (**a**) 1.0×10^1 kg (**b**) 1.0×10^4 kg (**c**) 1.1×10^6 kg (**d**) 9.3×10^6 kg

SAE 10.3 A vacuum pump is used to remove most of the gas in a container, ultimately producing a pressure of 10.5 torr inside the vessel. What is the pressure in the vessel in units of atm? (**a**) 1.38×10^{-2} atm (**b**) 10.6 atm (**c**) 7.98×10^2 atm (**d**) 1.06×10^5 atm

10.2 The Gas Laws

Learning Objectives

When you have finished Section 10.2, you should be able to:

- Use Boyle's law to predict how changes in the pressure of a fixed quantity of a gas held at constant temperature affect the volume of the gas and vice versa.
- Use Charles's law to predict how changes in the temperature of a fixed quantity of a gas held at constant pressure affect the volume of the gas and vice versa.
- Use Avogadro's law to predict how changes in the number of moles of a gas held at constant temperature and pressure are related to the volume the gas occupies.

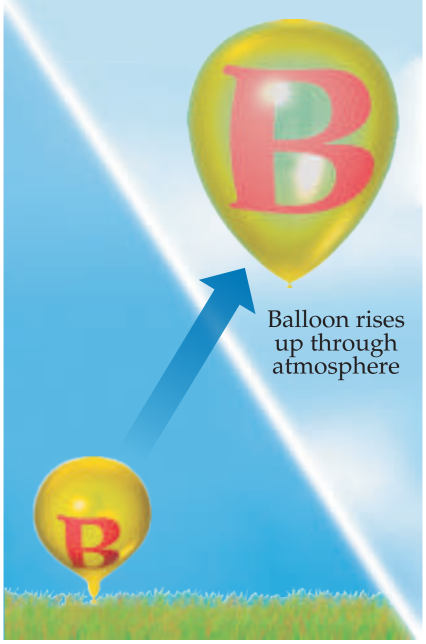
Four variables are needed to define the physical condition, or *state*, of a gas: temperature, pressure, volume, and amount of gas, usually expressed as number of moles. The equations that express the relationships among these four variables are known as the *gas laws*. Because volume is easily measured, the first gas laws to be studied expressed the effect of one of the variables on volume, with the remaining two variables held constant.

The Pressure–Volume Relationship: Boyle's Law

Gas volume increases as the pressure exerted on the gas decreases. Thus, an inflated weather balloon released at Earth's surface expands as it rises (**Figure 10.4**) because the pressure of the atmosphere decreases with increasing elevation.

Go Figure

Does atmospheric pressure increase or decrease as altitude increases? (Neglect changes in temperature.)



Balloon rises up through atmosphere

▲ **Figure 10.4 As a balloon rises in the atmosphere, its volume increases.**

The British chemist Robert Boyle (1627–1691) was the first person to investigate the quantitative relationship between the pressure of a gas and its volume. He found, for example, that decreasing the pressure of a gas to half its original value causes the volume to double. Conversely, doubling the pressure causes the volume to decrease to half its original value.

Boyle's law, which summarizes these observations, states that:

The volume of a fixed quantity of gas maintained at constant temperature is inversely proportional to the pressure.

When two measurements are inversely proportional, one gets smaller as the other gets larger. Boyle's law can be expressed mathematically as

$$V = \text{constant} \times \frac{1}{P} \quad \text{or} \quad PV = \text{constant} \qquad [10.2]$$

The value of the constant depends on temperature and on the amount of gas in the sample.

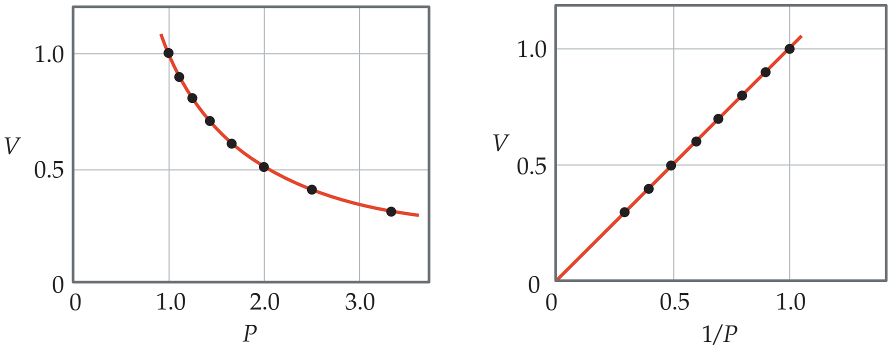
The graph of V versus P in **Figure 10.5** shows the curve obtained for a given quantity of gas at a fixed temperature. A linear relationship is obtained when V is plotted versus $1/P$ as shown on the right in Figure 10.5.

Boyle's law occupies a special place in the history of science because Boyle was the first to carry out experiments in which one variable was systematically changed to determine the effect on another variable. The data from the experiments were then employed to establish an empirical relationship—a "law."

We apply Boyle's law every time we breathe. The rib cage, which can expand and contract, and the diaphragm, a muscle beneath the lungs, govern the volume of the lungs. Inhalation occurs when the rib cage expands and the diaphragm moves downward. Both actions increase the volume of the lungs, thus decreasing the gas pressure inside the lungs. Atmospheric pressure then forces air into the lungs until the pressure in the lungs equals atmospheric pressure. Exhalation reverses the process—the rib cage contracts and the diaphragm moves up, decreasing the volume of the lungs. Air is forced out of the lungs by the resulting increase in pressure.

Go Figure

What would a plot of P versus $1/V$ look like for a fixed quantity of gas at a fixed temperature?



▲ **Figure 10.5 Boyle's law.** For a fixed quantity of gas at constant temperature, the volume of the gas is inversely proportional to its pressure.

The Temperature–Volume Relationship: Charles's Law

Figure 10.6 shows that the volume of an inflated balloon increases when the temperature of the gas inside the balloon increases and decreases when the temperature of the gas decreases. This relationship between gas volume and temperature was discovered in 1787 by French scientist Jacques Charles (1746–1823). Some typical volume–temperature data are shown in **Figure 10.7**. Notice that the extrapolated (dashed) line passes through −273 °C. Note also that the gas is predicted to have zero volume at this temperature. This condition is never realized, however, because all gases liquefy or solidify before reaching this temperature.

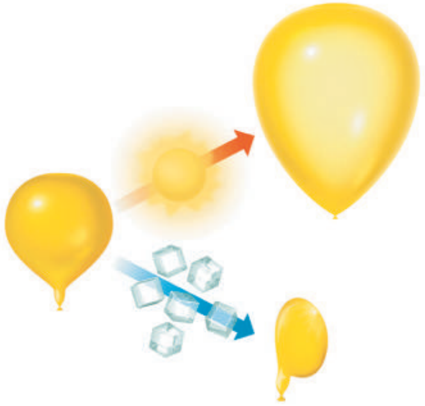
In 1848, William Thomson (1824–1907), a British physicist whose title was Lord Kelvin, proposed an absolute-temperature scale, now known as the Kelvin scale. On this scale, 0 K, called *absolute zero*, equals −273.15 °C. (Section 1.5) In terms of the Kelvin scale, **Charles's law** states the following:

> *The volume of a fixed amount of gas maintained at constant pressure is directly proportional to its absolute temperature.*

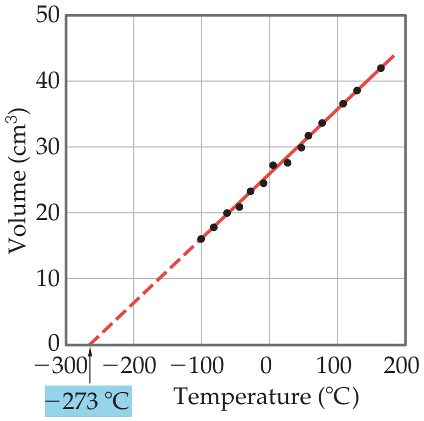
Thus, doubling the absolute temperature causes the gas volume to double. Mathematically, Charles's law takes the form

$$V = \text{constant} \times T \quad \text{or} \quad \frac{V}{T} = \text{constant} \qquad [10.3]$$

with the value of the constant depending on the pressure and on the amount of gas.



▲ **Figure 10.6 The effect of temperature on volume.**



▲ **Figure 10.7 Charles's law.** For a fixed quantity of gas at constant pressure, the volume of the gas is proportional to its temperature.

The Quantity–Volume Relationship: Avogadro's Law

The relationship between the quantity of a gas and its volume follows from the work of Joseph Louis Gay-Lussac (1778–1823) and Amedeo Avogadro (1776–1856).

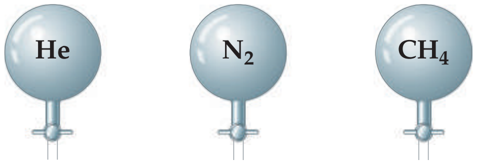
Gay-Lussac was one of those extraordinary figures in the history of science who could truly be called an adventurer. In 1804, he ascended to 23,000 feet in a hot-air balloon—an exploit that held the altitude record for several decades. To better control the balloon, Gay-Lussac studied the properties of gases. In 1808, he observed the *law of combining volumes*: At a given pressure and temperature, the volumes of gases that react with one another are in the ratios of small whole numbers. For example, two volumes of hydrogen gas react with one volume of oxygen gas to form two volumes of water vapor. (Section 3.1)

Three years later, Amedeo Avogadro interpreted Gay-Lussac's observation by proposing what is now known as **Avogadro's hypothesis**:

> *Equal volumes of gases at the same temperature and pressure contain equal numbers of molecules.*

For example, 22.4 L of any gas at 0 °C and 1 atm contain 6.02×10^{23} gas molecules (that is, 1 mol), as depicted in **Figure 10.8**.

Go Figure How many moles of gas are in each vessel?



Volume	22.4 L	22.4 L	22.4 L
Pressure	1 atm	1 atm	1 atm
Temperature	0 °C	0 °C	0 °C
Mass of gas	4.00 g	28.0 g	16.0 g
Number of gas molecules	6.02×10^{23}	6.02×10^{23}	6.02×10^{23}

▲ **Figure 10.8 Avogadro's hypothesis.** At the same volume, pressure, and temperature, samples of different gases have the same number of molecules but different masses.

Avogadro's law follows from Avogadro's hypothesis:

> *The volume of a gas maintained at constant temperature and pressure is directly proportional to the number of moles of the gas.*

That is,

$$V = \text{constant} \times n \quad \text{or} \quad \frac{V}{n} = \text{constant} \qquad [10.4]$$

where n is number of moles. Thus, doubling the number of moles of gas, for instance, causes the volume to double if T and P remain constant.

Sample Exercise 10.3

Evaluating the Effects of Changes in *P*, *V*, *n*, and *T* on a Gas

Suppose we have a gas confined to a cylinder with a movable piston that is sealed so there are no leaks. (Sections 5.2, 5.3) How will each of the following changes affect (i) the pressure of the gas, (ii) the number of moles of gas in the cylinder, (iii) the average distance between molecules? (**a**) Heating the gas while maintaining a constant pressure; (**b**) Reducing the volume while maintaining a constant temperature; (**c**) Injecting additional gas while keeping the temperature and volume constant.

SOLUTION

Analyze We need to think about how each change affects (1) the pressure of the gas, (2) the number of moles of gas in the cylinder, and (3) the average distance between molecules.

Plan We can use the gas laws to evaluate the changes in pressure. The number of moles of gas in the cylinder will not change unless gas is either added or removed. Assessing the average distance between molecules is not quite as straightforward. For a given number of gas molecules, the average distance between molecules increases as the volume increases. Conversely, for constant volume, the average distance between molecules decreases as the number of moles increases. Thus, the average distance between molecules will be proportional to V/n.

Solve

(**a**) Because it is stipulated that the pressure remains constant, pressure is not a variable in this problem, and the total number of moles of gas will also remain constant. We know from Charles's law, however, that heating the gas while maintaining constant pressure will cause the piston to move and the volume to increase. Thus, the distance between molecules will increase.

(**b**) The reduction in volume causes the pressure to increase (Boyle's law). Compressing the gas into a smaller volume does not change the total number of gas molecules; thus, the total number of moles remains the same. The average distance between molecules, however, must decrease because of the smaller volume.

(**c**) Injecting more gas into the cylinder means that more molecules are present and there will be an increase in the number of moles of gas in the cylinder. Because we have added more molecules while keeping the volume constant, the average distance between molecules must decrease. Avogadro's law tells us that the volume of the cylinder should have increased when we added more gas, provided the pressure and temperature were held constant. Here the volume is held constant, as is the temperature, which means the pressure must change. Knowing from Boyle's law that there is an inverse relationship between volume and pressure ($PV = \text{constant}$), we conclude that if the volume does not increase on injecting more gas, then the pressure must increase.

Practice Exercise

An oxygen cylinder used in a hospital contains 35.4 L of oxygen gas at a pressure of 149.6 atm. How much volume would the oxygen occupy if it were transferred to a container that maintained a pressure of 1.00 atm if the temperature remained constant?

Self-Assessment Exercises

SAE 10.4 If the pressure of a particular sample of a gas at constant temperature is doubled, what will happen to its volume? (**a**) It will double. (**b**) It will remain the same. (**c**) It will be cut in half. (**d**) It will be cut to a quarter of the original volume. (**e**) Not enough information is given to answer this question.

SAE 10.5 A gas is contained inside a flexible but impermeable membrane with a volume of 1.00 L and a temperature of 25 °C. If the gas is heated to 50 °C while keeping the pressure constant, what volume will it occupy? (**a**) 0.923 L (**b**) 1.00 L (**c**) 1.08 L (**d**) 2.00 L

SAE 10.6 Three balloons, each held at room temperature and each containing a different gas (methane, CH_4; nitrogen, N_2; and oxygen, O_2), have identical volumes. Which of the following does this imply? (**a**) The same number of atoms is present in each balloon. (**b**) The same number of molecules is present in each balloon. (**c**) The same mass of gas is present in each balloon. (**d**) More than one of these statements are true.

10.3 | The Ideal-Gas Equation

Learning Objectives

When you have finished Section 10.3, you should be able to:

- Calculate the pressure, volume, moles, or temperature of a gas using the ideal-gas equation.
- Calculate the density or molar mass of a gas using the ideal-gas equation.
- Use the ideal-gas equation and the concept of reaction stoichiometry to calculate the volume of gas produced or consumed in a reaction.

All three gas laws we just examined were obtained by holding two of the four variables P, V, T, and n constant and seeing how the remaining two variables affect each other. We can express each law as a proportionality relationship. Using the symbol $\propto$ for "is proportional to," we have

$$\textit{Boyle's law:}\quad V \propto \frac{1}{P} \quad (\text{constant } n, T)$$

$$\textit{Charles's law:}\quad V \propto T \quad (\text{constant } n, P)$$

$$\textit{Avogadro's law:}\quad V \propto n \quad (\text{constant } P, T)$$

We can combine these relationships into a general gas law:

$$V \propto \frac{nT}{P}$$

If we call the proportionality constant R, we obtain an equality:

$$V = R\left(\frac{nT}{P}\right)$$

which we can rearrange to

$$PV = nRT \qquad [10.5]$$

Equation 10.5 is the **ideal-gas equation** (also called the **ideal-gas law**). An **ideal gas** is a hypothetical gas whose pressure, volume, and temperature relationships are described completely by the ideal-gas equation.

In deriving the ideal-gas equation, we make two assumptions:

- the molecules of an ideal gas do not interact with one another, and
- the combined volume of the molecules is much smaller than the volume the gas occupies.

For these reasons, we consider the molecules as taking up no space in the container. In many cases, the small error introduced by these assumptions is acceptable. If more accurate calculations are needed, we can correct for the assumptions if we know something about the attraction molecules have for one another and the size of the molecules, as we explain in Section 10.7.

The term R in the ideal-gas equation is called the **gas constant**. The value and units of R depend on the units of P, V, n, and T. The value for T in the ideal-gas equation must *always* be the absolute temperature (in kelvins instead of degrees Celsius). The quantity of gas, n, is normally expressed in moles. The units chosen for pressure and volume are most often atmospheres and liters, respectively. However, other units can be used. In countries other than the United States, the pascal is the most commonly used unit for pressure. **Table 10.2** lists the numerical value for R in various units. In working with the ideal-gas equation, you must choose the form of R in which the units agree with the units of P, V, n, and T given in the problem. In this chapter, we most often use $R = 0.08206$ L-atm/mol-K because pressure is most often given in atmospheres.

Suppose we have 1.000 mol of an ideal gas at 1.000 atm and 0.00 °C (273.15 K). According to the ideal-gas equation, the volume of the gas is

$$V = \frac{nRT}{P}$$

$$= \frac{(1.000\ \cancel{\text{mol}})(0.08206\ \text{L-}\cancel{\text{atm}}/\cancel{\text{mol}}\text{-}\cancel{\text{K}})(273.15\ \cancel{\text{K}})}{1.000\ \cancel{\text{atm}}} = 22.41\ \text{L}$$

The conditions 0 °C and 1 atm are referred to as **standard temperature and pressure (STP)**. The volume occupied by 1 mol of ideal gas at STP, 22.41 L, is known as the *molar volume* of an ideal gas at STP.

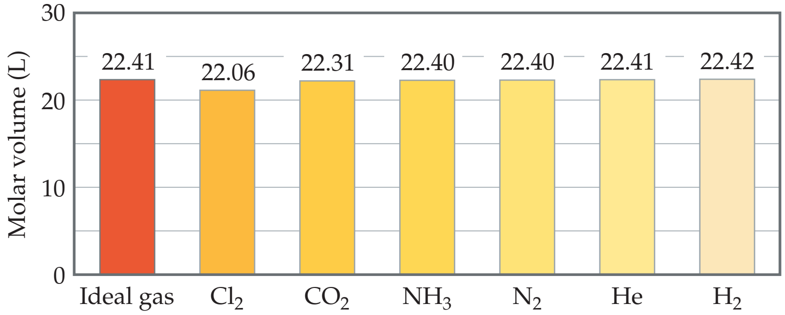
The ideal-gas equation accounts adequately for the properties of most gases under a variety of circumstances. The equation is not exactly correct, however, for any real gas. Thus, the measured volume for given values of P, n, and T might differ from the volume

TABLE 10.2 Numerical Values of the Gas Constant R in Various Units

Units	Numerical Value
L-atm/mol-K	0.08206
J/mol-K *	8.314
cal/mol-K	1.987
m^3-Pa/mol-K *	8.314
L-torr/mol-K	62.36

*SI unit

Go Figure Which gas deviates most from ideal behavior?



▲ **Figure 10.9** **Comparison of molar volumes of various gases at STP.**

calculated from $PV = nRT$ (**Figure 10.9**). Although real gases do not always behave ideally, their behavior differs so little from ideal behavior that we can ignore any deviations for all but the most accurate work.

Sample Exercise 10.4

Using the Ideal-Gas Equation

Calcium carbonate, $CaCO_3(s)$, the principal compound in limestone, decomposes upon heating to $CaO(s)$ and $CO_2(g)$. A sample of $CaCO_3$ is decomposed, and the carbon dioxide is collected in a 250-mL flask. After decomposition is complete, the gas has a pressure of 1.3 atm at a temperature of 31 °C. How many moles of CO_2 gas were generated?

SOLUTION

Analyze We are given the volume (250 mL), pressure (1.3 atm), and temperature (31 °C) of a sample of CO_2 gas and asked to calculate the number of moles of CO_2 in the sample.

Plan Because we are given V, P, and T, we can use the ideal-gas equation to solve for the unknown quantity, n.

Solve In analyzing and solving gas law problems, it is helpful to tabulate the information given in the problems and then to convert the values to units that are consistent with those for R(0.08206 L-atm/mol-K). In this case, the given values are

$$V = 250\text{ mL} = 0.250\text{ L}$$
$$P = 1.3\text{ atm}$$
$$T = 31\text{ °C} = (31 + 273)\text{ K} = 304\text{ K}$$

Remember: *Absolute temperature must always be used when the ideal-gas equation is solved.*

We now rearrange the ideal-gas equation (Equation 10.5) to solve for n

$$n = \frac{PV}{RT}$$

$$n = \frac{(1.3\,\cancel{\text{atm}})(0.250\,\cancel{\text{L}})}{(0.08206\,\cancel{\text{L-atm}}/\text{mol-}\cancel{\text{K}})(304\,\cancel{\text{K}})}$$

$$= 0.013\text{ mol } CO_2$$

Check Appropriate units cancel, thus ensuring that we have properly rearranged the ideal-gas equation and have converted to the correct units.

▶ **Practice Exercise**

Tennis balls are usually filled with either air or N_2 gas to a pressure above atmospheric pressure to increase their bounce. If a tennis ball has a volume of 144 cm^3 and contains 0.33 g of N_2 gas, what is the pressure inside the ball at 24 °C?

STRATEGIES FOR SUCCESS Calculations Involving Many Variables

In this chapter, we encounter a variety of problems based on the ideal-gas equation, which contains four variables—P, V, n, and T—and one constant, R. Depending on the type of problem, we might need to solve for any of the four variables.

To extract the necessary information from problems involving more than one variable, we suggest the following steps:

1. **Tabulate information.** Read the problems carefully to determine which variable is the unknown and which variables have numeric values given. Every time you encounter a numerical value, jot it down. In many cases, constructing a table of the given information will be useful.
2. **Convert to consistent units.** Make certain that quantities are converted to the proper units. In using the ideal-gas equation, for example, we usually use the value of R that has units of L-atm/mol-K. If you are given a pressure in torr, you will need to convert it to atmospheres before using this value of R in your calculations.

3. **If a single equation relates the variables, solve the equation for the unknown.** For the ideal-gas equation, these algebraic rearrangements will all be used at one time or another:

$$P = \frac{nRT}{V}, \quad V = \frac{nRT}{P}, \quad n = \frac{PV}{RT}, \quad T = \frac{PV}{nR}$$

4. **Use dimensional analysis.** Carry the units through your calculation. Using dimensional analysis enables you to check that you have solved an equation correctly. If the units in the equation cancel to give the units of the desired variable, you have probably used the equation correctly.

Sometimes you will not be given explicit values for several variables, making it look like a problem that cannot be solved. In these cases, however, you should look for information that can be used to determine the needed variables. For example, suppose you are using the ideal-gas equation to calculate a pressure in a problem that gives a value for T but not for n or V. However, the problem states that "the sample contains 0.15 mol of gas per liter." You can turn this statement into the expression

$$\frac{n}{V} = 0.15 \text{ mol/L}$$

Solving the ideal-gas equation for pressure yields

$$P = \frac{nRT}{V}$$

which we can rewrite as follows:

$$P = \left(\frac{n}{V}\right)RT$$

Thus, we can solve the equation even though we are not given explicit values for n and V.

As we have continuously stressed, the most important thing you can do to become proficient at solving chemistry problems is to do the Practice Exercises at the end of each Sample Exercise, the Self-Assessment Exercises at the end of each section, and the Exam Prep questions and the Exercises at the end of each chapter. By using systematic procedures, such as those described here, you should be able to minimize difficulties in solving problems involving many variables.

Relating the Ideal-Gas Equation and the Gas Laws

The gas laws we discussed in Section 10.2 are special cases of the ideal-gas equation. For example, when n and T are held constant, the product nRT contains three constants and so must itself be a constant:

$$PV = nRT = \text{constant} \quad \text{or} \quad PV = \text{constant} \qquad [10.6]$$

Note that this rearrangement gives Boyle's law. We see that if n and T are constant, the values of P and V can change, but the product PV must remain constant.

We can use Boyle's law to determine how the volume of a gas changes when its pressure changes. For example, if a cylinder fitted with a movable piston holds 50.0 L of O_2 gas at 18.5 atm and 21 °C, what volume will the gas occupy if the temperature is maintained at 21 °C while the pressure is reduced to 1.00 atm? Because the product PV is a constant when a gas is held at constant n and T, we know that

$$P_1V_1 = P_2V_2 \qquad [10.7]$$

where P_1 and V_1 are initial values and P_2 and V_2 are final values. Dividing both sides of this equation by P_2 gives the final volume, V_2:

$$V_2 = V_1 \times \frac{P_1}{P_2} = (50.0 \text{ L})\left(\frac{18.5 \cancel{\text{atm}}}{1.00 \cancel{\text{atm}}}\right) = 925 \text{ L}$$

The answer is reasonable because a gas expands as its pressure decreases.

In a similar way, we can start with the ideal-gas equation and derive relationships between any other two variables, V and T (Charles's law), n and V (Avogadro's law), or P and T.

We are often faced with the situation in which P, V, and T all change for a fixed number of moles of gas. Because n is constant in this situation, the ideal-gas equation gives

$$\frac{PV}{T} = nR = \text{constant}$$

If we represent the initial and final conditions by subscripts 1 and 2, respectively, we can write an equation that is often called the *combined gas law*:

$$\frac{P_1V_1}{T_1} = \frac{P_2V_2}{T_2} \qquad [10.8]$$

Sample Exercise 10.5

Calculating the Effect of Temperature Changes on Pressure

The gas pressure in an aerosol can is 1.5 atm at 25 °C. Assuming that the gas obeys the ideal-gas equation, what is the pressure when the can is heated to 450 °C?

SOLUTION

Analyze We are given the initial pressure (1.5 atm) and temperature (25 °C) of the gas and asked for the pressure at a higher temperature (450 °C).

Plan The volume and number of moles of gas do not change, so we must use a relationship connecting pressure and temperature. Converting temperature to the Kelvin scale and tabulating the given information, we have

	P	*T*
Initial	1.5 atm	298 K
Final	P_2	723 K

Solve To determine how *P* and *T* are related, we start with the ideal-gas equation and isolate the quantities that do not change (*n*, *V*, and *R*) on one side and the variables (*P* and *T*) on the other side.

$$\frac{P}{T} = \frac{nR}{V} = \text{constant}$$

Because the quotient P/T is a constant, we can write

$$\frac{P_1}{T_1} = \frac{P_2}{T_2}$$

(where the subscripts 1 and 2 represent the initial and final states, respectively). Rearranging to solve for P_2 and substituting, we have that the given data give

$$P_2 = (1.5\ \text{atm})\left(\frac{723\ \cancel{\text{K}}}{298\ \cancel{\text{K}}}\right) = 3.6\ \text{atm}$$

Check This answer is intuitively reasonable—increasing the temperature of a gas increases its pressure.

Comment It is evident from this example why aerosol cans carry a warning not to incinerate.

▶ Practice Exercise

The pressure in a natural-gas tank is maintained at 2.20 atm. On a day when the temperature is −15 °C, the volume of gas in the tank is $3.25 \times 10^3\ \text{m}^3$. What is the volume of the same quantity of gas on a day when the temperature is 31 °C?

Sample Exercise 10.6

Using the Combined Gas Laws

An inflated balloon has a volume of 6.0 L at sea level (1.0 atm) and is allowed to ascend until the pressure is 0.45 atm. During ascent, the temperature of the gas falls from 22 °C to −21 °C. Calculate the volume of the balloon at its final altitude.

SOLUTION

Analyze We need to determine a new volume for a gas sample when both pressure and temperature change.

Plan Let's again proceed by converting temperatures to kelvins and tabulating our information.

	P	*V*	*T*
Initial	1.0 atm	6.0 L	295 K
Final	0.45 atm	V_2	252 K

Because *n* is constant, we can use Equation 10.8.

Solve Rearranging Equation 10.8 to solve for V_2 gives

$$V_2 = V_1 \times \frac{P_1}{P_2} \times \frac{T_2}{T_1}$$

$$= (6.0\ \text{L})\left(\frac{1.0\ \cancel{\text{atm}}}{0.45\ \cancel{\text{atm}}}\right)\left(\frac{252\ \cancel{\text{K}}}{295\ \cancel{\text{K}}}\right) = 11\ \text{L}$$

Check The result appears reasonable. Notice that the calculation involves multiplying the initial volume by a ratio of pressures and a ratio of temperatures. Intuitively, we expect decreasing pressure to cause the volume to increase, while decreasing the temperature should have the opposite effect. Because the change in pressure is more dramatic than the change in temperature, we expect the effect of the pressure change to predominate in determining the final volume, as it does.

▶ Practice Exercise

A 0.50-mol sample of oxygen gas is confined at 0 °C and 1.0 atm in a cylinder with a movable piston. The piston compresses the gas so that the final volume is half the initial volume and the final pressure is 2.2 atm. What is the final temperature of the gas in degrees Celsius?

Gas Densities and Molar Mass

Recall that density has units of mass per unit volume ($d = m/V$). (Section 1.5) We can arrange the ideal-gas equation to obtain similar units of moles per unit volume:

$$\frac{n}{V} = \frac{P}{RT}$$

If we multiply both sides of this equation by the molar mass, $\mathcal{M}$, which is the number of grams in 1 mol of a substance (Section 3.4), we obtain

$$\frac{n\mathcal{M}}{V} = \frac{P\mathcal{M}}{RT} \qquad [10.9]$$

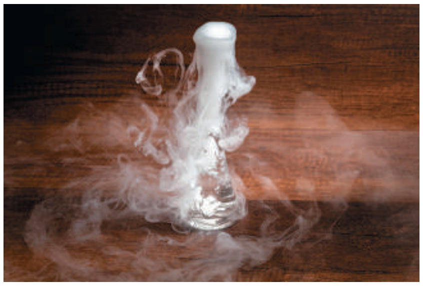
The term on the left equals the density in grams per liter:

$$\frac{\text{moles}}{\text{liter}} \times \frac{\text{grams}}{\text{mole}} = \frac{\text{grams}}{\text{liter}}$$

Thus, the density of the gas is also given by the expression on the right in Equation 10.9:

$$d = \frac{n\mathcal{M}}{V} = \frac{P\mathcal{M}}{RT} \qquad [10.10]$$

Equation 10.10 tells us that the density of a gas depends on its pressure, molar mass, and temperature. The higher the molar mass and pressure, the denser the gas. The higher the temperature, the less dense the gas. Although gases form homogeneous mixtures, a less dense gas will lie above a denser gas in the absence of mixing. For example, CO_2 has a higher molar mass than N_2 or O_2 and is therefore denser than air. For this reason, CO_2 released from a CO_2 fire extinguisher blankets a fire, preventing O_2 from reaching the combustible material. “Dry ice,” which is solid CO_2, converts directly to CO_2 gas at room temperature, and the resulting “fog” (which is actually condensed water droplets cooled by the CO_2) is carried downward by the heavier, but colorless, CO_2 (**Figure 10.10**).



▲ **Figure 10.10** **Carbon dioxide gas flows downward because it is denser than air.**

Sample Exercise 10.7

Calculating Gas Density

What is the density of carbon tetrachloride vapor at 714 torr and 125 °C?

SOLUTION

Analyze We are asked to calculate the density of a gas given its name, its pressure, and its temperature. From the name, we can write the chemical formula of the substance and determine its molar mass.

Plan We can use Equation 10.10 to calculate the density. Before we can do that, however, we must convert the given quantities to the appropriate units—namely, degrees Celsius to kelvins and pressure to atmospheres. We must also calculate the molar mass of CCl_4.

Solve The absolute temperature is $125 + 273 = 398$ K. The pressure is $(714\,\cancel{\text{torr}})(1\text{ atm}/760\,\cancel{\text{torr}}) = 0.939$ atm. The molar mass of CCl_4 is $12.01 + (4)(35.45) = 153.8$ g/mol. Therefore,

$$d = \frac{P\mathcal{M}}{RT} = \frac{(0.939\,\cancel{\text{atm}})(153.8\text{ g}/\cancel{\text{mol}})}{(0.08206\text{ L-}\cancel{\text{atm}}/\cancel{\text{mol}}\text{-}\cancel{\text{K}})(398\,\cancel{\text{K}})} = 4.42\text{ g/L}$$

Check If we divide molar mass (g/mol) by density (g/L), we end up with L/mol. The numerical value is roughly $154/4.4 = 35$, which is in the right ballpark for the molar volume of a gas heated to 125 °C at near atmospheric pressure. We may thus conclude our answer is reasonable.

▶ **Practice Exercise**

The mean molar mass of the gases in the atmosphere at the surface of Titan, Saturn’s largest moon, is 28.6 g/mol. The surface temperature is 95 K, and the pressure is 1.6 atm. Assuming ideal behavior, calculate the density of Titan’s atmosphere.

When we have equal molar masses of two gases at the same pressure but different temperatures, the hotter gas is less dense than the cooler one, so the hotter gas rises. The difference between the densities of hot and cold air is responsible for the lift of hot-air balloons. It is also responsible for many phenomena in weather, such as the formation of large thunderheads during thunderstorms.

Equation 10.10 can be rearranged to solve for the molar mass of a gas:

$$\mathcal{M} = \frac{dRT}{P} \qquad [10.11]$$

Thus, we can use the experimentally measured density of a gas to determine the molar mass of the gas molecules, as shown in Sample Exercise 10.8.

Sample Exercise 10.8

Calculating the Molar Mass of a Gas

A large evacuated flask initially has a mass of 134.567 g. When the flask is filled with a gas of unknown molar mass to a pressure of 735 torr at 31 °C, its mass is 137.328 g. When the flask is evacuated again and then filled with water at 31 °C, its mass is 1067.9 g. (The density of water at this temperature is 0.997 g/mL.) Assuming the ideal-gas equation applies, calculate the molar mass of the gas.

SOLUTION

Analyze We are given the temperature (31 °C) and pressure (735 torr) for a gas, together with information to determine its volume and mass, and we are asked to calculate its molar mass.

Plan The data obtained when the flask is filled with water can be used to calculate the volume of the container. The mass of the empty flask and of the flask when filled with gas can be used to calculate the mass of the gas. From these quantities we calculate the gas density and then apply Equation 10.11 to calculate the molar mass of the gas.

Solve The gas volume equals the volume of water the flask can hold, calculated from the mass and density of the water. The mass of the water is the difference between the masses of the full and evacuated flask:

$$1067.9\ \text{g} - 134.567\ \text{g} = 933.3\ \text{g}$$

Rearranging the equation for density ($d = m/V$), we have

$$V = \frac{m}{d} = \frac{(933.3\ \cancel{\text{g}})}{(0.997\ \cancel{\text{g}}/\text{mL})} = 936\ \text{mL} = 0.936\ \text{L}$$

The gas mass is the difference between the mass of the flask filled with gas and the mass of the evacuated flask:

$$137.328\ \text{g} - 134.567\ \text{g} = 2.761\ \text{g}$$

Knowing the mass of the gas (2.761 g) and its volume (0.936 L), we can calculate the density of the gas:

$$d = 2.761\ \text{g}/0.936\ \text{L} = 2.95\ \text{g/L}$$

After converting pressure to atmospheres and temperature to kelvins, we can use Equation 10.11 to calculate the molar mass:

$$\begin{aligned}\mathcal{M} &= \frac{dRT}{P}\\ &= \frac{(2.95\ \text{g}/\cancel{\text{L}})(0.08206\ \cancel{\text{L}}\text{-}\cancel{\text{atm}}/\text{mol-}\cancel{\text{K}})(304\ \cancel{\text{K}})}{(0.967\ \cancel{\text{atm}})}\\ &= 76.1\ \text{g/mol}\end{aligned}$$

Check The units work out appropriately, and the value of molar mass obtained is reasonable for a substance that is gaseous near room temperature.

▶ Practice Exercise

Calculate the average molar mass of dry air if it has a density of 1.17 g/L at 21 °C and 740.0 torr.

Volumes of Gases in Chemical Reactions

We are often concerned with knowing the identity and/or quantity of a gas involved in a chemical reaction. Thus, it is useful to be able to calculate the volumes of gases consumed or produced in reactions. Such calculations are based on the mole concept and balanced chemical equations. (Section 3.6) The coefficients in a balanced chemical equation tell us the relative amounts (in moles) of reactants and products in a reaction. The ideal-gas equation relates the number of moles of a gas to P, V, and T.

Sample Exercise 10.9

Relating Gas Variables and Reaction Stoichiometry

Automobile air bags are inflated by nitrogen gas generated by the rapid decomposition of sodium azide, NaN_3:

$$2\ NaN_3(s) \longrightarrow 2\ Na(s) + 3\ N_2(g)$$

If an air bag has a volume of 36 L and is to be filled with nitrogen gas at 1.15 atm and 26 °C, how many grams of NaN_3 must be decomposed?

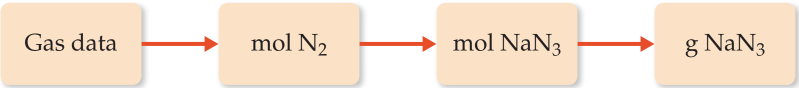
SOLUTION

Analyze This is a multistep problem. We are given the volume, pressure, and temperature of the N_2 gas and the chemical equation for the reaction by which the N_2 is generated. We must use this information to calculate the number of grams of NaN_3 needed to obtain the necessary N_2.

Plan We need to use the gas data (P, V, and T) and the ideal-gas equation to calculate the number of moles of N_2 gas that should be formed for the air bag to operate correctly. We can then use the balanced equation to determine the number of moles of NaN_3 needed. Finally, we can convert moles of NaN_3 to grams.

Solve

The conversion sequence is:



The number of moles of N_2 is determined using the ideal-gas equation:

$$n = \frac{PV}{RT} = \frac{(1.15\ \cancel{\text{atm}})(36\ \cancel{\text{L}})}{(0.08206\ \cancel{\text{L-atm}}/\text{mol-}\cancel{\text{K}})(299\ \cancel{\text{K}})}$$

$$= 1.7\ \text{mol}\ N_2$$

We use the coefficients in the balanced equation to calculate the number of moles of NaN_3:

$$(1.7\ \cancel{\text{mol}\ N_2})\frac{2\ \text{mol}\ NaN_3}{(3\ \cancel{\text{mol}\ N_2})} = 1.1\ \text{mol}\ NaN_3$$

Finally, using the molar mass of NaN_3, we convert moles of NaN_3 to grams:

$$(1.1\ \cancel{\text{mol}\ NaN_3})\frac{65.0\ \text{g}\ NaN_3}{(1\ \cancel{\text{mol}\ NaN_3})} = 72\ \text{g}\ NaN_3$$

Check The units cancel properly at each step in the calculation, leaving us with the correct units in the answer, g NaN_3.

▶ **Practice Exercise**

In the first step of the industrial process for making nitric acid, ammonia reacts with oxygen in the presence of a suitable catalyst to form nitric oxide and water vapor:

$$4\,NH_3(g) + 5\,O_2(g) \longrightarrow 4\,NO(g) + 6\,H_2O(g)$$

How many liters of $NH_3(g)$ at 850 °C and 5.00 atm are required to react with 1.00 mol of $O_2(g)$ in this reaction?

Self-Assessment Exercises

SAE 10.7 Which situation will result in an increased temperature of a gaseous sample? (**a**) increasing the pressure of a fixed quantity of gas in a rigid vessel (**b**) decreasing the volume of a balloon for a fixed quantity of gas at constant pressure (**c**) increasing the number of moles of gas in a rigid vessel at constant pressure (**d**) simultaneously doubling the pressure and halving the volume of a balloon that holds a fixed quantity of gas

SAE 10.8 A sample of oxygen at a temperature of 20 °C occupies a volume of 335 mL. How many moles of gas are present if the pressure is 0.998 atm? (**a**) 1.37×10^{-4} mol (**b**) 0.0139 mol (**c**) 0.204 mol (**d**) 13.9 mol

SAE 10.9 A sample of N_2 gas at a temperature of 25 °C and a pressure of 750 torr is sealed inside a glass container of unknown volume. If the container is heated to 250 °C, what is the pressure of the gas inside the container? (**a**) 75.0 torr (**b**) 427 torr (**c**) 1320 torr (**d**) 7500 torr

SAE 10.10 What is the density of neon in a vessel where the temperature is 35 °C and the pressure is 15.0 torr? (**a**) 0.00684 g/L (**b**) 0.0158 g/L (**c**) 0.128 g/L (**d**) 12.0 g/L

SAE 10.11 If sodium hydrogen carbonate is added to a hydrochloric acid solution, it will produce gaseous carbon dioxide according to the following reaction:

$$NaHCO_3(s) + HCl(aq) \longrightarrow NaCl(aq) + H_2O(l) + CO_2(g)$$

How many grams of $NaHCO_3$ must be added to an excess of $HCl(aq)$ to produce 50.0 mL of CO_2 at 25 °C and 0.995 atm? (**a**) 0.00203 g (**b**) 2.04 g (**c**) 171 g (**d**) 0.170 g

10.4 | Gas Mixtures and Partial Pressures

Learning Objectives

When you finish Section 10.4, you should be able to:

- ▶ Calculate the partial pressure of each gas, and the total pressure of all gases, in a mixture of gases.
- ▶ Interconvert between the mole fraction of a gas in a mixture and its partial pressure.

Thus far we have considered mainly pure gases—those that consist of only one substance in the gaseous state. How do we deal with mixtures of two or more different, nonreacting gases? While studying the properties of air, John Dalton (Section 2.1) made an important observation:

The total pressure of a mixture of gases equals the sum of the pressures that each would exert if it were present alone.

The pressure exerted by a particular component of a mixture of gases is called the **partial pressure** of that component. Dalton's observation is known as **Dalton's law of partial pressures**.

If we let P_t be the total pressure of a mixture of gases and P_1, P_2, P_3, and so forth be the partial pressures of the individual gases, we can write Dalton's law of partial pressures as

$$P_t = P_1 + P_2 + P_3 + \dots \qquad [10.12]$$

This equation implies that each gas behaves independently of the others, as we can see by the following analysis. Let n_1, n_2, n_3, and so forth be the number of moles of each of the gases in the mixture and let n_t be the total number of moles of gas. If each gas obeys the ideal-gas equation, we can write

$$P_1 = n_1\left(\frac{RT}{V}\right); \quad P_2 = n_2\left(\frac{RT}{V}\right); \quad P_3 = n_3\left(\frac{RT}{V}\right); \quad \text{and so forth}$$

All of the gases in a container must occupy the same volume and will come to the same temperature in a relatively short period of time. Using these facts to simplify Equation 10.12, we obtain

$$P_t = (n_1 + n_2 + n_3 + \ldots)\left(\frac{RT}{V}\right) = n_t\left(\frac{RT}{V}\right) \qquad [10.13]$$

That is, at constant temperature and constant volume, the total pressure of a gas sample is determined by the total number of moles of gas present, whether that total represents just one gas or a mixture of gases.

Sample Exercise 10.10

Applying Dalton's Law of Partial Pressures

A mixture of 6.00 g of $O_2(g)$ and 9.00 g of $CH_4(g)$ is placed in a 15.0-L vessel at 0 °C. What is the partial pressure of each gas, and what is the total pressure in the vessel?

SOLUTION

Analyze We need to calculate the pressure for two gases in the same volume and at the same temperature.

Plan Because each gas behaves independently, we can use the ideal-gas equation to calculate the pressure each would exert if the other were not present. Per Dalton's law, the total pressure is the sum of these two partial pressures.

Solve We first convert the mass of each gas to moles:

$$n_{O_2} = (6.00\,\text{g}\,\cancel{O_2})\left(\frac{1\ \text{mol}\ O_2}{32.0\ \text{g}\,\cancel{O_2}}\right) = 0.188\ \text{mol}\ O_2$$

$$n_{CH_4} = (9.00\,\text{g}\,\cancel{CH_4})\left(\frac{1\ \text{mol}\ CH_4}{16.0\ \text{g}\,\cancel{CH_4}}\right) = 0.563\ \text{mol}\ CH_4$$

We use the ideal-gas equation to calculate the partial pressure of each gas:

$$P_{O_2} = \frac{n_{O_2}RT}{V} = \frac{(0.188\ \cancel{\text{mol}})(0.08206\ \cancel{\text{L}}\text{-atm}/\cancel{\text{mol}}\text{-}\cancel{\text{K}})(273\ \cancel{\text{K}})}{15.0\ \cancel{\text{L}}}$$
$$= 0.281\ \text{atm}$$

$$P_{CH_4} = \frac{n_{CH_4}RT}{V} = \frac{(0.563\ \cancel{\text{mol}})(0.08206\ \cancel{\text{L}}\text{-atm}/\cancel{\text{mol}}\text{-}\cancel{\text{K}})(273\ \cancel{\text{K}})}{15.0\ \cancel{\text{L}}}$$
$$= 0.841\ \text{atm}$$

According to Dalton's law of partial pressures (Equation 10.12), the total pressure in the vessel is the sum of the partial pressures:

$$P_t = P_{O_2} + P_{CH_4}$$
$$= 0.281\ \text{atm} + 0.841\ \text{atm} = 1.122\ \text{atm}$$

Check A pressure of roughly 1 atm seems right for a mixture of about 0.2 mol O_2 and a bit more than 0.5 mol CH_4, together in a 15-L volume, because 1 mol of an ideal gas at 1 atm pressure and 0 °C occupies about 22 L.

Practice Exercise

What is the total pressure exerted by a mixture of 2.00 g of $H_2(g)$ and 8.00 g of $N_2(g)$ at 273 K in a 10.0-L vessel?

Partial Pressures and Mole Fractions

Because each gas in a mixture behaves independently, we can relate the amount of a given gas in a mixture to its partial pressure. For an ideal gas, we can write

$$\frac{P_1}{P_t} = \frac{n_1RT/V}{n_tRT/V} = \frac{n_1}{n_t} \qquad [10.14]$$

The ratio n_1/n_t is called the *mole fraction of gas 1*, which we denote X_1. The **mole fraction**, X, is a dimensionless number that expresses the ratio of the number of moles of one component in a mixture to the total number of moles in the mixture. Thus, for gas 1 we have

$$X_1 = \frac{\text{moles of compound 1}}{\text{total moles}} = \frac{n_1}{n_t} \qquad [10.15]$$

We can combine Equations 10.14 and 10.15 to give

$$P_1 = \left(\frac{n_1}{n_t}\right)P_t = X_1P_t \qquad [10.16]$$

The mole fraction of N_2 in air is 0.78—that is, 78% of the molecules in air are N_2. This means that if the barometric pressure is 760 torr, the partial pressure of N_2 is

$$P_{N_2} = (0.78)(760 \text{ torr}) = 590 \text{ torr}$$

This result makes intuitive sense: Because N_2 makes up 78% of the mixture, it contributes 78% of the total pressure.

Sample Exercise 10.11

Relating Mole Fractions and Partial Pressures

A study of the effects of certain gases on plant growth requires a synthetic atmosphere composed of 1.5 mol % CO_2, 18.0 mol % O_2 and 80.5 mol % Ar. (**a**) Calculate the partial pressure of O_2 in the mixture if the total pressure of the atmosphere is 745 torr. (**b**) If this atmosphere is held in a 121-L space at 295 K, how many moles of O_2 are needed?

SOLUTION

Analyze For (**a**) we need to calculate the partial pressure of O_2 given its mole percent and the total pressure of the mixture. For (**b**) we need to calculate the number of moles of O_2 in the mixture given its volume (121 L), temperature (295 K), and partial pressure from part (a).

Plan We calculate the partial pressures using Equation 10.16, and then use P_{O_2}, V, and T in the ideal-gas equation to calculate the number of moles of O_2.

Solve

(**a**) The mole percent is the mole fraction times 100. Therefore, the mole fraction of O_2 is 0.180. Equation 10.16 gives:

$$P_{O_2} = (0.180)(745 \text{ torr}) = 134 \text{ torr}$$

(**b**) Tabulating the given variables and converting to appropriate units, we have:

$$P_{O_2} = (134 \cancel{\text{torr}})\left(\frac{1 \text{ atm}}{760 \cancel{\text{torr}}}\right) = 0.176 \text{ atm}$$

$$V = 121 \text{ L}$$

$$n_{O_2} = ?$$

$$R = 0.08206 \frac{\text{L-atm}}{\text{mol-K}}$$

$$T = 295 \text{ K}$$

Solving the ideal-gas equation for n_{O_2}, we have:

$$n_{O_2} = P_{O_2}\left(\frac{V}{RT}\right)$$

$$= (0.176 \cancel{\text{atm}})\frac{121 \cancel{\text{L}}}{(0.08206 \cancel{\text{L}}\text{-}\cancel{\text{atm}}/\text{mol-}\cancel{\text{K}})(295 \cancel{\text{K}})} = 0.880 \text{ mol}$$

Check The units check out, and the answer seems to be the right order of magnitude.

Practice Exercise

From data gathered by the *Voyager 1* space probe, scientists have estimated the composition of the atmosphere of Titan, Saturn's largest moon. The pressure on the surface of Titan is 1220 torr. The atmosphere consists of 82 mol% N_2, 12 mol% Ar, and 6.0 mol% CH_4. Calculate the partial pressure of each gas.

Self-Assessment Exercises

SAE 10.12 A cylinder with a volume of 15 L contains 95 mol% N_2 and 5 mol% H_2, and the total pressure is 2.0×10^6 Pa. If 12 g of H_2 is injected into the cylinder while the temperature is held constant, the total pressure will ______ and the partial pressure of N_2 will ______. (**a**) increase, increase (**b**) increase, not change (**c**) not change, increase (**d**) not change, not change (**e**) increase, decrease

SAE 10.13 Water can be decomposed into its constituent elements, $2\,H_2O(l) \longrightarrow 2\,H_2(g) + O_2(g)$, with an electrical current in a process called electrolysis. If 1.2 g of H_2O is subjected to electrolysis and the products are collected in a cylinder with a volume of 0.20 L and a temperature of 30 °C, what is the partial pressure of H_2? (**a**) 0.55 atm (**b**) 2.8 atm (**c**) 5.5 atm (**d**) 8.3 atm

10.5 The Kinetic-Molecular Theory of Gases

Learning Objectives

When you finish Section 10.5, you should be able to:

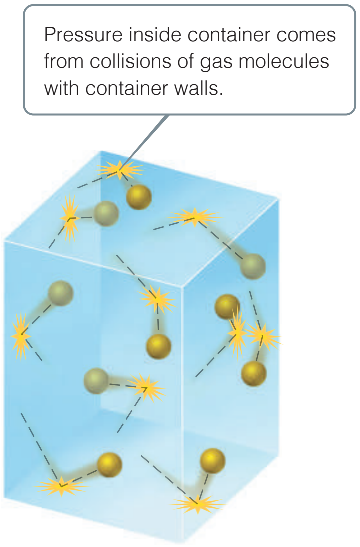
- Describe the five assumptions of the kinetic-molecular theory of gases.
- Use the kinetic-molecular theory to relate macroscopic properties of gases to their microscopic behavior.
- Describe qualitatively how the distribution of molecular speeds in a sample of gas changes with temperature and molecular weight.

The ideal-gas equation describes *how* gases behave but not *why* they behave as they do. Why does a gas expand when heated at constant pressure? Or why does its pressure increase when the gas is compressed at constant temperature? To understand the physical properties of gases, we need a model that helps us picture what happens to gas particles when conditions such as pressure or temperature change. Such a model, known as the **kinetic-molecular theory of gases**, was developed over a period of about 100 years, culminating in 1857 when Rudolf Clausius (1822–1888) published a complete and satisfactory form of the theory.

The kinetic-molecular theory (the theory of moving molecules) is summarized by the following statements:

1. **Random motion** Gases consist of large numbers of molecules that are in continuous, random motion. (The word *molecule* is used here to designate the smallest particle of any gas, even though some gases, such as the noble gases, consist of individual atoms. All we learn about gas behavior from the kinetic-molecular theory applies equally to atomic gases.)
2. **Negligible molecular volume** The combined volume of all the molecules of the gas is negligible relative to the total volume in which the gas is contained.
3. **Negligible forces** Attractive and repulsive forces between gas molecules are negligible.
4. **Constant average kinetic energy** Energy can be transferred between molecules during collisions, but, as long as temperature remains constant, the *average* kinetic energy of the molecules does not change with time.
5. **Average kinetic energy proportional to temperature** The average kinetic energy of the molecules is proportional to the absolute temperature. At any given temperature, the molecules of all gases have the same average kinetic energy.

The kinetic-molecular theory explains both pressure and temperature at the molecular level. The pressure of a gas is caused by collisions of the molecules with the walls of the container (**Figure 10.11**). The magnitude of the pressure is determined by how often and how forcefully the molecules strike the walls.



Pressure inside container comes from collisions of gas molecules with container walls.

▲ **Figure 10.11 The molecular origin of gas pressure.**

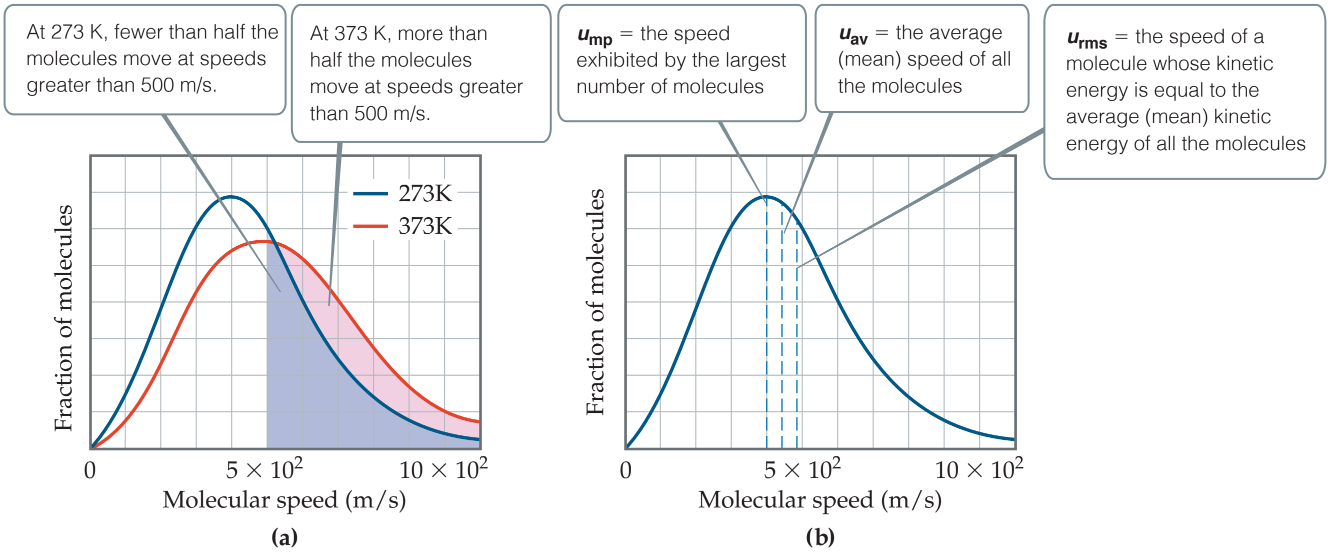
The absolute temperature of a gas is a measure of the *average* kinetic energy of its molecules. If two gases are at the same temperature, their molecules have the same average kinetic energy (statement 5 of the kinetic-molecular theory). If the absolute temperature of a gas is doubled, the average kinetic energy of its molecules doubles. Thus, molecular motion increases with increasing temperature.

Distributions of Molecular Speed

Although collectively the molecules in a sample of gas have an *average* kinetic energy and hence an average speed, the individual molecules are moving at different speeds. Each molecule collides frequently with other molecules. Momentum is conserved in each collision, but one of the colliding molecules might be deflected off at high speed while the other is nearly stopped. The result is that, at any instant, the molecules in the sample have a wide range of speeds. In **Figure 10.12**(a), which shows the distribution of molecular speeds for nitrogen gas at 273 K and 373 K, notice that a larger fraction of the molecules at 373 K moves at the higher speeds. This means that the sample at 373 K has the higher average kinetic energy.

In any graph of the distribution of molecular speeds in a gas sample, the peak of the curve represents the most probable speed, u_{mp} [Figure 10.12(b)]. The most probable speeds in Figure 10.12(a), for instance, are 4×10^2 m/s for the sample at 273 K and 5×10^2 m/s for the sample at 373 K. Figure 10.12(b) also shows the **root-mean-square (rms) speed**, u_{rms}, of the molecules. This is the speed of a molecule possessing a kinetic energy identical to the average kinetic energy of the sample. The rms speed is not quite

Go Figure Estimate the fraction of molecules at 373 K with speeds less than 300 m/s.



At 273 K, fewer than half the molecules move at speeds greater than 500 m/s.

At 373 K, more than half the molecules move at speeds greater than 500 m/s.

u_{mp} = the speed exhibited by the largest number of molecules

u_{av} = the average (mean) speed of all the molecules

u_{rms} = the speed of a molecule whose kinetic energy is equal to the average (mean) kinetic energy of all the molecules

▲ **Figure 10.12 Distribution of molecular speeds for nitrogen gas.** (**a**) The effect of temperature on molecular speed. The relative area under the curve for a range of speeds gives the relative fraction of molecules that have those speeds. (**b**) Position of most probable (u_{mp}), average (u_{av}), and root-mean-square (u_{rms}) speeds of gas molecules. The data shown here are for nitrogen gas at 273 K.

the same as the average (mean) speed, u_{av}, because the shape of the distribution curve is not symmetric; there is a longer tail toward larger molecular speeds. The difference between the two is small, however. In Figure 10.12(b), for example, the root-mean-square speed is about 4.9×10^2 m/s, whereas the average speed is about 4.5×10^2 m/s.

If you calculate the rms speeds (as we will later), you will find that the rms speed is almost 6×10^2 m/s for the sample at 373 K, but slightly less than 5×10^2 m/s for the sample at 273 K. Notice that the distribution curve broadens and flattens as we go to a higher temperature, which tells us that the range of molecular speeds increases with temperature.

The rms speed is important because the average kinetic energy of the gas molecules in a sample is equal to $\frac{1}{2}m(u_{rms})^2$. (Section 1.4) Because mass does not change with temperature, the increase in the average kinetic energy $\frac{1}{2}m(u_{rms})^2$ as the temperature increases implies that the rms speed of the molecules (as well as u_{av} and u_{mp}) increases as temperature increases.

Application of the Kinetic-Molecular Theory to the Gas Laws

The empirical observations of gas properties as expressed by the various gas laws are readily understood in terms of the kinetic-molecular theory. The following examples illustrate this point:

1. **An increase in volume at constant temperature causes pressure to decrease.** A constant temperature means that the average kinetic energy of the gas molecules remains unchanged. This means that the rms speed of the molecules remains unchanged. When the volume is increased, the molecules must move a longer distance between collisions. Consequently, there are fewer collisions per unit time with the container walls, which means the pressure decreases. Thus, kinetic-molecular theory explains Boyle's law.
2. **A temperature increase at constant volume causes pressure to increase.** An increase in temperature means an increase in the average kinetic energy of the molecules and in u_{rms}. Because there is no change in volume, the temperature

increase causes more collisions with the walls per unit time because the molecules are all moving faster. Furthermore, the momentum in each collision increases (the molecules strike the walls more forcefully). A greater number of more forceful collisions means the pressure increases, and the theory explains this increase.

A CLOSER LOOK The Ideal-Gas Equation

The ideal-gas equation can be derived from the five statements given in the text for the kinetic-molecular theory. Rather than perform the derivation, however, let's consider in qualitative terms how the ideal-gas equation might follow from these statements. The total force of the molecular collisions on the walls and hence the pressure (force per unit area, Section 10.1) produced by these collisions depend both on how strongly the molecules strike the walls (impulse imparted per collision) and on the rate at which the collisions occur:

$$P \propto \text{impulse imparted per collision} \times \text{collision rate}$$

For a molecule traveling at the rms speed, the impulse imparted by a collision with a wall depends on the momentum of the molecule; that is, it depends on the product of the molecule's mass and speed: mu_{rms}. The collision rate is proportional to the number of molecules per unit volume, n/V, and to their speed, which is u_{rms} because we are talking about only molecules traveling at this speed. Thus, we have

$$P \propto mu_{\text{rms}} \times \frac{n}{V} \times u_{\text{rms}} \propto \frac{nm(u_{\text{rms}})^2}{V} \qquad [10.17]$$

Because the average kinetic energy, $\frac{1}{2}m(u_{\text{rms}})^2$, is proportional to temperature, we have $m(u_{\text{rms}})^2 \propto T$. Making this substitution in Equation 10.17 gives

$$P \propto \frac{nm(u_{\text{rms}})^2}{V} \propto \frac{nT}{V} \qquad [10.18]$$

If we put in a proportionality constant, calling it R, the gas constant, you can see that we obtain the ideal-gas equation:

$$P = \frac{nRT}{V} \qquad [10.19]$$

Related Exercises: 10.75, 10.76

Sample Exercise 10.12

Applying the Kinetic-Molecular Theory

A sample of O_2 gas initially at STP is compressed to a smaller volume at constant temperature. What effect does this change have on (**a**) the average kinetic energy of the molecules, (**b**) their average speed, (**c**) the number of collisions they make with the container walls per unit time, (**d**) the number of collisions they make with a unit area of container wall per unit time, and (**e**) the pressure?

SOLUTION

Analyze We need to apply the concepts of the kinetic-molecular theory of gases to a gas compressed at constant temperature.

Plan We will determine how each of the quantities in (a)–(e) is affected by the change in volume at constant temperature.

Solve (**a**) Because the average kinetic energy of the O_2 molecules is determined only by temperature, this energy is unchanged by the compression. (**b**) Because the average kinetic energy of the molecules does not change, their average speed remains constant. (**c**) The number of collisions with the walls per unit time increases because the molecules are moving in a smaller volume but with the same average speed as before. Under these conditions they will strike the walls of the container more frequently. (**d**) The number of collisions with a unit area of wall per unit time increases because the total number of collisions with the walls per unit time increases and the area of the walls decreases. (**e**) Although the average force with which the molecules collide with the walls remains constant, the pressure increases because there are more collisions per unit area of wall per unit time.

Check In a conceptual exercise of this kind, there is no numerical answer to check. All we can check in such cases is our reasoning in the course of solving the problem. The increase in pressure seen in part (**e**) is consistent with Boyle's law.

▶ Practice Exercise

How is the rms speed of N_2 molecules in a gas sample changed by (**a**) an increase in temperature, (**b**) an increase in volume, and (**c**) mixing with a sample of Ar at the same temperature?

Self-Assessment Exercises

SAE 10.14 Which of these statements is an assumption of the kinetic-molecular theory of gases? (**a**) Larger gas molecules take up more volume than smaller gas molecules. (**b**) Gas molecules lose energy every time they collide with something, so over time the molecules will stop moving, no matter what the conditions. (**c**) At a given temperature, all gas molecules move with the same speed. (**d**) Gas molecules neither attract nor repel each other.

SAE 10.15 A gas is contained in a closed piston–cylinder apparatus. If the cylinder is raised so that the enclosed volume of the gas doubles but the temperature is kept constant, which of the following statements are *true*?

(**i**) The pressure of the gas will decrease.
(**ii**) The average kinetic energy of the gas molecules will decrease.
(**iii**) The rate of collisions with the cylinder walls will decrease.

(**a**) only i (**b**) both i and ii (**c**) both i and iii (**d**) both ii and iii (**e**) All three statements are true.

SAE 10.16 Two flasks of equal volume, one containing argon (Ar) and the other containing krypton (Kr), are kept at the same temperature. The pressure inside both flasks is the same, and both gases are assumed to behave as ideal gases. According to the kinetic-molecular theory of gases, the average kinetic energy of the argon atoms is _____ the average kinetic energy of the krypton atoms, and the average speed of the argon atoms is _____ than the average speed of the krypton atoms.

(**a**) less than, the same speed (**b**) equal to, faster than (**c**) greater than, faster than (**d**) equal to, the same speed as **(e)** less than, slower than

SAE 10.17 Which of the following statements best describes what a graph of "number of molecules" versus "molecular speed" for a particular gas at a particular temperature would look like? (**a**) a vertical line, because all gas molecules have the same speed at the same temperature (**b**) a straight line with a negative slope, indicating that the largest number of molecules have the smallest speeds (**c**) a symmetric bell-shaped curve, indicating that the most probable speed of gas molecules is the same as the average speed (**d**) an asymmetric bell-shaped curve, indicating that the most probable speed of gas molecules is smaller than the average speed (**e**) an asymmetric bell-shaped curve, indicating that the most probable speed of gas molecules is larger than the average speed

10.6 | Molecular Speeds, Effusion, and Diffusion

Learning Objectives

When you finish Section 10.6, you should be able to:

- Calculate the root-mean-square speed, average speed, and the most probable speed of gas molecules, for a given gas at constant temperature.
- Use Graham's law of effusion to predict the behavior of effusing gases.
- Predict how the mean free path of a diffusing gas molecule will be affected by changes in pressure.

According to the kinetic-molecular theory of gases, the average kinetic energy of *any* collection of gas molecules, $\frac{1}{2}m(u_{\text{rms}})^2$, has a specific value at a given temperature. Thus, for two gases at the same temperature, a gas composed of low-mass particles, such as He, has the same average kinetic energy as one composed of more massive particles, such as Xe. The mass of the particles in the He sample is smaller than that in the Xe sample. Consequently, the He particles must have a higher rms speed than the Xe particles. Equation 10.20 expresses this fact quantitatively:

$$u_{\text{rms}} = \sqrt{\frac{3RT}{\mathcal{M}}} \qquad [10.20]$$

where $\mathcal{M}$ is the molar mass of the particles. Equation 10.20 can be derived from the kinetic-molecular theory. Because $\mathcal{M}$ appears in the denominator, the rms speed increases as the molar mass of the gas particles decreases.

Figure 10.13 shows the distribution of molecular speeds for several gases at 298 K. Notice how the distributions are shifted toward higher speeds for gases of lower molar masses.

The most probable speed of a gas molecule can also be derived:

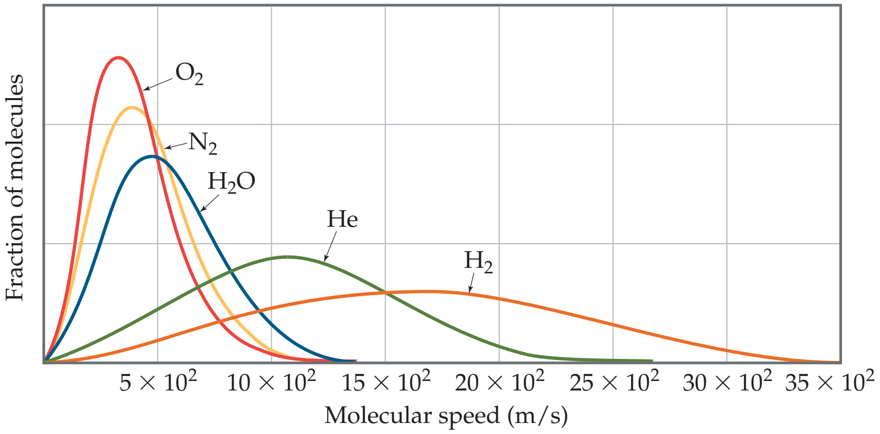
$$u_{\text{mp}} = \sqrt{\frac{2RT}{\mathcal{M}}} \qquad [10.21]$$

Finally, the average speed of a gas molecule can be derived:

$$u_{\text{av}} = \sqrt{\frac{8RT}{\pi\mathcal{M}}} \qquad [10.22]$$

Go Figure

Which of these gases has the largest molar mass? Which has the smallest?



▲ **Figure 10.13** **The effect of molar mass on molecular speed at 298 K.**

Notice that the formulas for u_{rms}, u_{mp}, and u_{av} all show that the speed is proportional to the square root of $T/\mathcal{M}$. Hence, the speed will increase as T increases and will decrease as $\mathcal{M}$ increases.

The dependence of molecular speed on mass has two interesting consequences. The first is **effusion**, which is the escape of gas molecules through a tiny hole (**Figure 10.14**). The second is **diffusion**, which is the spread of one substance throughout a space or throughout a second substance. For example, the molecules of a perfume diffuse throughout a room once the bottle is opened.

Sample Exercise 10.13

Calculating a Root-Mean-Square Speed

Calculate the rms speed of the molecules in a sample of N_2 gas at 25 °C.

SOLUTION

Analyze We are given the identity of a gas and the temperature, the two quantities we need to calculate the rms speed.

Plan We calculate the rms speed using Equation 10.20.

Solve We must convert each quantity in our equation to SI units. We will also use R in units of J/mol-K (Table 10.2) to make the units cancel correctly.

$$T = 25 + 273 = 298\text{ K}$$

$$\mathcal{M} = 28.0\text{ g/mol} = 28.0 \times 10^{-3}\text{ kg/mol}$$

$$R = 8.314\text{ J/mol-K} = 8.314\text{ kg-m}^2/\text{s}^2\text{-mol-K (Since 1 J} = 1\text{ kg-m}^2/\text{s}^2)$$

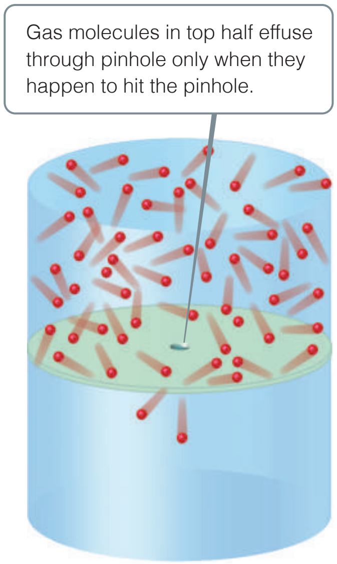
$$u_{\text{rms}} = \sqrt{\frac{3RT}{\mathcal{M}}}$$

$$= \sqrt{\frac{3(8.314\,\cancel{\text{kg}}\text{-m}^2/\text{s}^2\text{-}\cancel{\text{mol}}\text{-}\cancel{\text{K}})(298\,\cancel{\text{K}})}{28.0 \times 10^{-3}\,\cancel{\text{kg}}/\cancel{\text{mol}}}} = 5.15 \times 10^2\text{ m/s}$$

Comment This corresponds to a speed of 1150 mi/hr. Because the molecular weight of O_2 molecules is slightly greater than that of N_2, the rms speed of O_2 molecules is a little less than that for N_2 at the same temperature.

▶ Practice Exercise

What is the rms speed of an atom in a sample of He gas at 25 °C?



Gas molecules in top half effuse through pinhole only when they happen to hit the pinhole.

▲ **Figure 10.14** **Effusion.**

Graham's Law of Effusion

In 1846, Thomas Graham (1805–1869) discovered that the effusion rate of a gas is inversely proportional to the square root of its molar mass. Assume we have two gases at the same temperature and pressure in two containers with identical pinholes. If the rates of effusion of the two gases are r_1 and r_2 and their molar masses are $\mathcal{M}_1$ and $\mathcal{M}_2$, **Graham's law** states that

$$\frac{r_1}{r_2} = \sqrt{\frac{\mathcal{M}_2}{\mathcal{M}_1}} \qquad [10.23]$$

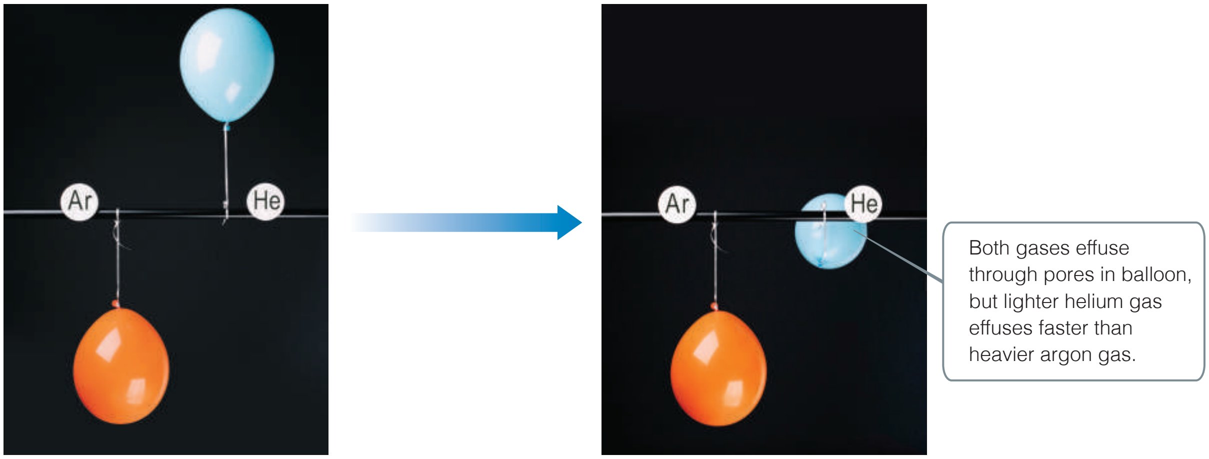
a relationship that indicates that the lighter gas has the higher effusion rate.

The only way for a molecule to escape from its container is for it to "hit" the hole in the partitioning wall of Figure 10.14. The faster the molecules are moving, the more often they hit the partition wall and the greater the likelihood that a molecule will hit the hole and effuse. This implies that the rate of effusion is directly proportional to the rms speed of the molecules. Because R and T are constant, we have, from Equation 10.22

$$\frac{r_1}{r_2} = \frac{u_{\text{rms1}}}{u_{\text{rms2}}} = \sqrt{\frac{3RT/\mathcal{M}_1}{3RT/\mathcal{M}_2}} = \sqrt{\frac{\mathcal{M}_2}{\mathcal{M}_1}} \qquad [10.24]$$

As expected from Graham's law, helium escapes from containers through tiny pinhole leaks more rapidly than other gases of higher molecular weight (**Figure 10.15**).

Go Figure Because pressure and temperature are constant in this figure but volume changes, which other quantity in the ideal-gas equation must also change?



Both gases effuse through pores in balloon, but lighter helium gas effuses faster than heavier argon gas.

▲ **Figure 10.15** **An illustration of Graham's law of effusion.**

Sample Exercise 10.14

Applying Graham's Law

An unknown gas composed of homonuclear diatomic molecules effuses at a rate that is 0.355 times the rate at which O_2 gas effuses at the same temperature. Calculate the molar mass of the unknown and identify it.

SOLUTION

Analyze We are given the rate of effusion of an unknown gas relative to that of O_2 and asked to find the molar mass and identity of the unknown. Thus, we need to connect relative rates of effusion to relative molar masses.

Plan We use Equation 10.23 to determine the molar mass of the unknown gas. If we let r_x and $\mathcal{M}_x$ represent the rate of effusion and molar mass of the gas, we can write

$$\frac{r_x}{r_{O_2}} = \sqrt{\frac{\mathcal{M}_{O_2}}{\mathcal{M}_x}}$$

Solve From the information given,

$$r_x = 0.355 \times r_{O_2}$$

Thus,

$$\frac{r_x}{r_{O_2}} = 0.355 = \sqrt{\frac{32.0\ \text{g/mol}}{\mathcal{M}_x}}$$

$$\frac{32.0\ \text{g/mol}}{\mathcal{M}_x} = (0.355)^2 = 0.126$$

$$\mathcal{M}_x = \frac{32.0\ \text{g/mol}}{0.126} = 254\ \text{g/mol}$$

Because we are told that the unknown gas is composed of homonuclear diatomic molecules, it must be an element. The molar mass must represent twice the atomic weight of the atoms in the unknown gas. We conclude that the unknown gas must have an atomic weight of 127g/mol, in which case the molecule is I_2.

▶ **Practice Exercise**

Calculate the ratio of the effusion rates of N_2 gas and O_2 gas.

Diffusion and Mean Free Path

Although diffusion, like effusion, is faster for lower-mass molecules than for higher-mass ones, molecular collisions make diffusion more complicated than effusion.

Graham's law, Equation 10.23, approximates the ratio of the diffusion rates of two gases under identical conditions. We can see from the horizontal axis in Figure 10.12 that the speeds of molecules are quite high. For example, the rms speed of molecules of N_2 gas at room temperature is 515 m/s. In spite of this high speed, if someone opens a vial of perfume at one end of a room, some time elapses—perhaps a few minutes—before the scent is detected at the other end of the room. This tells us that the diffusion rate of gases throughout a volume of space is much slower than molecular speeds.* This difference is due to molecular collisions, which occur frequently for a gas at atmospheric pressure—about 10^{10} times per second for each molecule. Collisions occur because real gas molecules have finite volumes.

---

*The rate at which the perfume moves across the room also depends on how well stirred the air is from temperature gradients and the movement of people. Nevertheless, even with the aid of these factors, it still takes much longer for the molecules to traverse the room than one would expect from their rms speed.

Because of molecular collisions, a gas molecule's direction of motion is constantly changing. A good mathematical approximation to this motion is the "random walk,"

CHEMISTRY AND SUSTAINABILITY HYDROGEN AND HELIUM

Hydrogen and helium are by far the most abundant elements in the universe. Together they account for 75% of the mass of the universe, yet they are only present in trace amounts in Earth's atmosphere. The concentration of He is 5 parts per million (ppm) and that of H_2 is roughly 10 times smaller, ~0.5 ppm. Why is this the case? One reason is that given their very light masses, H_2 molecules and He atoms not only have a faster average speed than other gases, they also have a broader distribution, which produces some molecules that are moving very fast (Figure 10.12). Consequently, they are more likely to achieve sufficient velocities to overcome the gravitational attraction to Earth and escape into space. It is estimated that Earth loses about 3 kg of $H_2(g)$ and about 50 g of He per second in this way.

Hydrogen is a feedstock for many important chemical reactions and forms the basis for a potential "hydrogen economy." The combination reaction between hydrogen and oxygen to create water and release energy is central to the idea of the hydrogen economy.

$$2\,H_2(g) + O_2(g) \longrightarrow 2\,H_2O(g) \quad \Delta H_{rxn} = -572\ \text{kJ/mol}$$

This is the same process (although with liquids, not gases) that is used to boost rockets into space, illustrating the significant amount of chemical energy this reaction releases (**Figure 10.16**). Unlike fossil fuel combustion, this reaction does not produce CO_2, making it a highly attractive prospect for combating climate change. Unfortunately, the main way to generate elemental hydrogen is through steam reforming of the fossil fuel methane, represented by the following reaction:

$$CH_4(g) + H_2O(g) \longrightarrow CO(g) + 3H_2(g)$$

Thus, a frontier area of scientific research is to develop methods to safely and efficiently obtain hydrogen that do not rely on fossil fuels like methane (and produce a toxic gas like CO). For instance, you could convert water to hydrogen and oxygen using a process called electrolysis; but that would cost at least 572 kJ/mol to run.

Helium is probably best known as the inert gas that makes balloons and airships float, a property that takes advantage of its low density, but that is far from its only use. It is also used in welding, in the manufacture of electronics, and in the detection of leaks. Helium liquifies when cooled below 4.2 K, and this very low boiling point leads to its most important commercial application. Liquid helium is used to cool many high-tech instruments, including the superconducting magnets of magnetic resonance imaging machines found in hospitals.

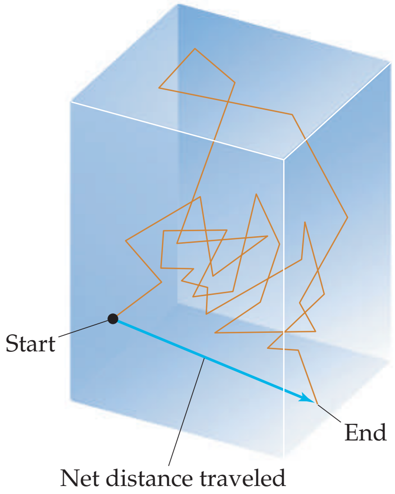
Helium is found, surprisingly, in subterranean natural gas deposits where it is formed when much heavier radioactive elements, like uranium and thorium, decay. After the natural gas is pumped out of the ground, helium can be isolated from the other components by distillation. Over the course of the twentieth century, the U.S. government took on a major role in providing a stable and affordable supply of helium. The National Helium Reserve, located near Amarillo, Texas, is a strategic reserve that held over 1 billion cubic meters of the gas at its peak. Starting in the mid-1990s, the federal government started to slowly but steadily privatize the collection, storage, and sale of liquid helium. This has led to concerns about the supply and price of this valuable commodity. As of this writing (spring 2021), liquid helium costs approximately \$38/L, more than many good wines.

Related Exercise: 10.86

▲ **Figure 10.16** **Hydrogen and oxygen combine to form water, releasing enough energy to power this rocket into space.**

the details of which are beyond the scope of this book. For our purposes, it is sufficient to know that the diffusion of a molecule from one point to another consists of many short, straight-line segments as collisions buffet it around in random directions (Figure 10.17).

The average distance traveled by a molecule between collisions, called the molecule's **mean free path**, varies with pressure as the following analogy illustrates. Imagine walking through a shopping mall. When the mall is crowded (high pressure), the average distance you can walk before bumping into someone is short (short mean free path). When the mall is empty (low pressure), you can walk a long way (long mean free path) before bumping into someone. The mean free path for air molecules at sea level is about 60 nm. At about 100 km in altitude, where the air pressure is much lower, the mean free path is about 10 cm, over 1 million times longer than at Earth's surface. For a given volume and temperature, the distance between collisions will decrease as the number of molecules increases. An increase in the number of molecules at constant T and V corresponds to an increase in P, so it makes sense that the mean free path is inversely proportional to the pressure of the gas.



▲ **Figure 10.17 Diffusion of a gas molecule.** For clarity, no other gas molecules in the container are shown.

Self-Assessment Exercises

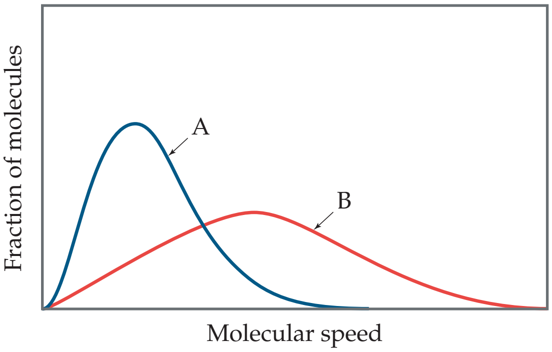
SAE 10.18 What is the most probable speed of $H_2(g)$ molecules at 5500 °C, the surface temperature of the Sun? (**a**) 2.20×10^2 m/s (**b**) 6.8×10^3 m/s (**c**) 6.9×10^3 m/s (**d**) 8.5×10^3 m/s

SAE 10.19 N_2 gas is allowed to effuse through a porous membrane under constant pressure conditions. It takes 212 s for 1.0 L of N_2 gas to pass through the membrane. If it takes 337 s for 1.0 L of an unknown gas to effuse through the membrane under identical conditions, what is the molar mass of the unknown gas? (**a**) 11 g/mol (**b**) 19 g/mol (**c**) 44 g/mol (**d**) 71 g/mol

SAE 10.20 Which of the following is the correct rank order of the diffusion rates of either Cl_2 or H_2S through air at a pressure of 1.0 atm?

(**a**) H_2S at 300 K < H_2S at 250 K < Cl_2 at 300 K < Cl_2 at 250 K
(**b**) H_2S at 250 K < H_2S at 300 K < Cl_2 at 250 K < Cl_2 at 300 K
(**c**) Cl_2 at 300 K < Cl_2 at 250 K < H_2S at 300 K < H_2S at 250 K
(**d**) Cl_2 at 250 K < Cl_2 at 300 K < H_2S at 250 K < H_2S at 300 K

SAE 10.21 Which statement is *true* about the following plot?



(**a**) If both curves represent the same gas, then A is at high temperature and B is at low temperature. (**b**) The average speed of the gas molecules in the B sample is about half that in the A sample. (**c**) If these curves represent two different gases at the same temperature, then A has a higher molar mass than B. (**d**) For most gases at temperatures near room temperature, the horizontal axis would span 1–100 m/s.

10.7 | Real Gases: Deviations from Ideal Behavior

Learning Objectives

When you have finished Section 10.7, you should be able to:

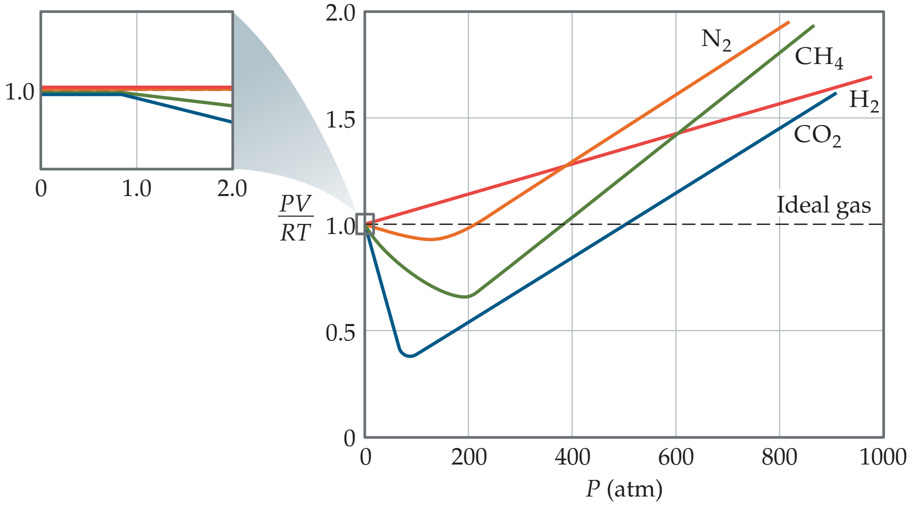
- Recognize conditions that lead to deviations from the ideal-gas law and explain why those deviations occur.
- Use the van der Waals equation to calculate the characteristic properties of real gases.

Using the ideal-gas law for many situations is a good first step. In the real world, however, gases may not always behave ideally. We must therefore examine cases where the ideal-gas law must be modified.

The extent to which a real gas departs from ideal behavior can be seen by rearranging the ideal-gas equation to solve for n:

$$\frac{PV}{RT} = n \qquad [10.25]$$

This form of the equation tells us that for 1 mol of ideal gas, the quantity PV/RT equals 1 at all pressures. In Figure 10.18, PV/RT is plotted as a function of P for 1 mol of several real gases. At high pressures (generally above 10 atm), the deviation from ideal behavior ($PV/RT = 1$) is large and different for each gas. *Real gases, in other words, do not behave ideally at high pressure.* At lower pressures (usually below 10 atm), however, the deviation from ideal behavior is small, and we can use the ideal-gas equation without generating serious error.



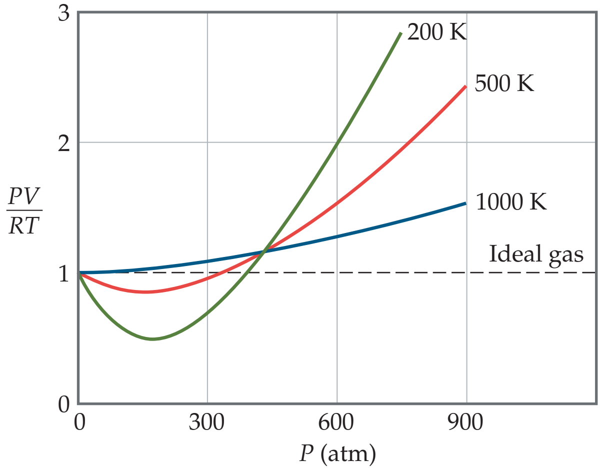
▲ **Figure 10.18 The effect of pressure on the behavior of several real gases.** Data for 1 mol of gas in all cases. The data were taken at 300 K for N_2, CH_4, and H_2, whereas they were taken at 313 K for CO_2 because under high pressure CO_2 liquefies at 300 K.

Deviation from ideal behavior also depends on temperature. As temperature increases, the behavior of a real gas more nearly approaches that of the ideal gas (**Figure 10.19**). In general, *the deviation from ideal behavior increases as temperature decreases*, becoming significant near the temperature at which the gas liquefies.

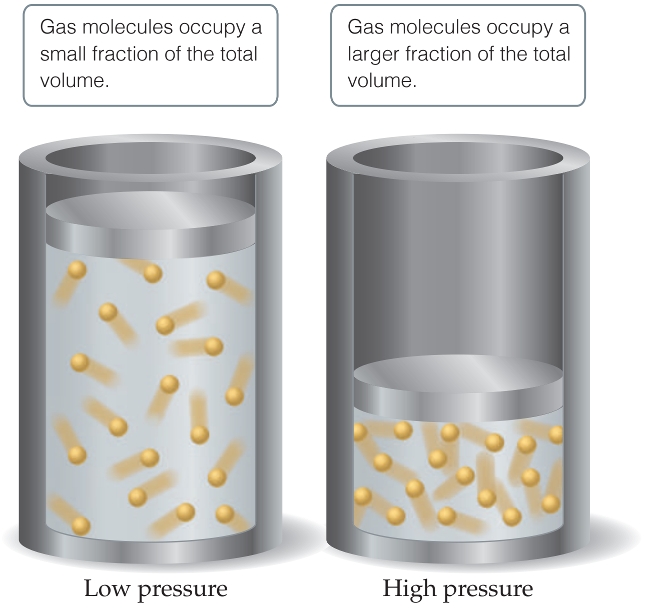
The basic assumptions of the kinetic-molecular theory of gases give us insight into why real gases deviate from ideal behavior. The molecules of an ideal gas are assumed to occupy no space and have no attraction for one another. *Real molecules, however, do have finite volumes and do attract one another*. As **Figure 10.20** shows, the unoccupied space in which real molecules can move is less than the container volume. At low pressures, the combined volume of the gas molecules is negligible relative to the container volume. Thus, the unoccupied volume available to the molecules is essentially the container volume. At high pressures, the combined volume of the gas molecules is *not* negligible relative to the container volume. Now the unoccupied volume available to the molecules is less than the container volume. At high pressures, therefore, gas volumes tend to be slightly greater than those predicted by the ideal-gas equation.

Go Figure

True or false: Nitrogen gas behaves more like an ideal gas as the temperature increases.



▲ **Figure 10.19 The effect of temperature and pressure on the behavior of nitrogen gas.**



Gas molecules occupy a small fraction of the total volume.
Gas molecules occupy a larger fraction of the total volume.
Low pressure
High pressure

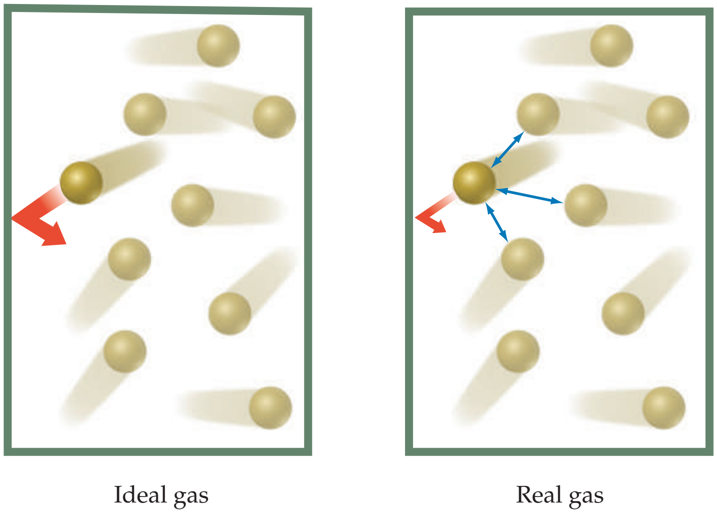
◀ **Figure 10.20 Gases behave more ideally at low pressure than at high pressure.**

Another reason for nonideal behavior at high pressures is that the attractive forces between molecules come into play at the short intermolecular distances found when molecules are crowded together at high pressures. Because of these attractive forces, the impact of a given molecule with the container wall is lessened. If we could stop the motion in a gas, as illustrated in **Figure 10.21**, we would see that a molecule about to collide with the wall experiences the attractive forces of nearby molecules. These attractions lessen the force with which the molecule hits the wall. As a result, the gas pressure is less than that of an ideal gas. This effect decreases PV/RT to below its ideal value, as seen at the lower pressures in Figures 10.18 and 10.19. When the pressure is sufficiently high, however, the volume effects dominate and PV/RT increases to above the ideal value.

Temperature determines how effective attractive forces between gas molecules are in causing deviations from ideal behavior at lower pressures. Figure 10.19 shows that, at pressures below about 400 atm, cooling increases the extent to which a gas deviates from

Go Figure

How would you expect the pressure of a gas to change if suddenly the intermolecular forces were repulsive rather than attractive?



▲ **Figure 10.21 In any real gas, attractive intermolecular forces reduce pressure to values lower than in an ideal gas.**

ideal behavior. As the gas cools, the average kinetic energy of the molecules decreases. This drop in kinetic energy means the molecules do not have the energy needed to overcome intermolecular attraction, and the molecules will be more likely to stick to each other than bounce off each other.

As the temperature of a gas increases—as, say, from 200 to 1000 K in Figure 10.19—the negative deviation of PV/RT from the ideal value of 1 disappears. As noted earlier, the deviations seen at high temperatures stem mainly from the effect of the finite volumes of the molecules.

The van der Waals Equation

Engineers and scientists who work with gases at high pressures often cannot use the ideal-gas equation because departures from ideal behavior are too large. One useful equation developed to predict the behavior of real gases was proposed by the Dutch scientist Johannes van der Waals (1837–1923).

As we have seen, a real gas has a lower pressure due to intermolecular forces, and a larger volume due to the finite volume of the molecules, relative to an ideal gas. Van der Waals recognized that it would be possible to retain the form of the ideal-gas equation, $PV = nRT$, if corrections were made to the pressure and the volume. He introduced two constants for these corrections: a, a measure of how strongly the gas molecules attract one another, and b, a measure of the finite volume occupied by the molecules. His description of gas behavior is known as the **van der Waals equation**:

$$\left(P + \frac{n^2a}{V^2}\right)(V - nb) = nRT \qquad [10.26]$$

The term n^2a/V^2 accounts for the attractive forces. The equation adjusts the pressure upward by adding n^2a/V^2 because attractive forces between molecules tend to reduce the pressure (Figure 10.21). The added term has the form n^2a/V^2 because the attractive force between pairs of molecules increases as the square of the number of molecules per unit volume, $(n/V)^2$.

The term nb accounts for the small but finite volume occupied by the gas molecules (Figure 10.20). The van der Waals equation subtracts nb to adjust the volume downward to give the volume that would be available to the molecules in the ideal case. The constants a and b, called *van der Waals constants*, are experimentally determined positive quantities that differ from one gas to another. Notice in **Table 10.3** that a and b generally increase with increasing molecular mass. Larger, more massive molecules have larger volumes and tend to have greater intermolecular attractive forces.

TABLE 10.3 Van der Waals Constants for Gas Molecules

Substance	a (L^2-atm/mol^2)	b (L/mol)
He	0.0341	0.02370
Ne	0.211	0.0171
Ar	1.34	0.0322
Kr	2.32	0.0398
Xe	4.19	0.0510
H_2	0.244	0.0266
N_2	1.39	0.0391
O_2	1.36	0.0318

CO_2	3.59	0.0427
CCl_4	20.4	0.1383

Sample Exercise 10.15

Using the van der Waals Equation

If 10.00 mol of an ideal gas were confined to 22.41 L at 0.0 °C, it would exert a pressure of 10.00 atm. Use the van der Waals equation and Table 10.3 to estimate the pressure exerted by 10.00 mol of $Cl_2(g)$ in 22.41 L at 0.0 °C.

SOLUTION

Analyze We need to determine a pressure. Because we will use the van der Waals equation, we must identify the appropriate values for the constants in the equation.

Plan Rearrange Equation 10.26 to isolate P.

Solve Substituting $n = 10.00\text{ mol}$, $R = 0.08206\text{ L-atm/mol-K}$, $T = 273.2\text{ K}$, $V = 22.41\text{ L}$, $a = 6.49\text{ L}^2\text{-atm/mol}^2$, and $b = 0.0562\text{ L/mol}$:

$$P = nRT/(V - nb) - n^2a/V^2$$

$$= \frac{(10.00\ \cancel{\text{mol}})(0.08206\ \cancel{\text{L}}\text{-atm}/\cancel{\text{mol}}\text{-}\cancel{\text{K}})(273.2\ \cancel{\text{K}})}{22.41\ \cancel{\text{L}} - (10.00\ \cancel{\text{mol}})(0.0562\ \cancel{\text{L}}/\cancel{\text{mol}})}$$

$$- \frac{(10.00\ \cancel{\text{mol}})^2(6.49\ \cancel{\text{L}^2}\text{-atm}/\cancel{\text{mol}^2})}{(22.41\ \cancel{\text{L}})^2}$$

$$= 10.26\text{ atm} - 1.29\text{ atm} = 8.97\text{ atm}$$

Comment Notice that the term 10.26 atm is the pressure corrected for molecular volume. This value is higher than the ideal value, 10.00 atm, because the volume in which the molecules are free to move is smaller than the container volume, 22.41 L. Thus, the molecules collide more frequently with the container walls, and the pressure is higher than that of a real gas. The term 1.29 atm makes a correction in the opposite direction for intermolecular forces. The correction for intermolecular forces is the larger of the two, and thus the pressure 8.97 atm is smaller than would be observed for an ideal gas.

Practice Exercise

A sample of 1.000 mol of $CO_2(g)$ is confined to a 3.000-L container at 0.000 °C. Calculate the pressure of the gas using (**a**) the ideal-gas equation and (**b**) the van der Waals equation.

Self-Assessment Exercises

SAE 10.22 Which of the following statements regarding the behavior of real gases is *false*? (**a**) As the attractions between molecules increase, the value of the constant b in the van der Waals equation increases. (**b**) Deviations from ideal-gas behavior are more pronounced at high pressures because the molecules experience greater attractions to one another. (**c**) Deviations from ideal-gas behavior are more pronounced at high pressures because the fraction of space occupied by molecules becomes nonnegligible. (**d**) Deviations from ideal-gas behavior are more pronounced at low temperatures because the molecules experience greater attractions to one another.

SAE 10.23 Based on their respective van der Waals constants, is Ar ($a = 1.34$, $b = 0.0322$) or CO_2 ($a = 3.59$, $b = 0.0427$) expected to behave more nearly like an ideal gas at high pressures? (**a**) It is Ar, because both the a and b parameters are smaller than that of CO_2. (**b**) It is CO_2, because both the a and b parameters are larger than that of Ar. (**c**) The deviation from ideal behavior depends only on T—the pressure has no effect. (**d**) Both gases would behave quite similarly at high pressure.

Putting Concepts Together

Cyanogen, a highly toxic gas, is 46.2% C and 53.8% N by mass. At 25 °C and 751 torr, 1.05 g of cyanogen occupies 0.500 L. (**a**) What is the molecular formula of cyanogen? Predict (**b**) its molecular structure and (**c**) its polarity.

SOLUTION

Analyze We need to determine the molecular formula of a gas from elemental analysis data and data on its properties. Then we need to predict the structure of the molecule and from that, its polarity.

(**a**) **Plan** We can use the percentage composition of the compound to calculate its empirical formula. (Section 3.5) Then we can determine the molecular formula by comparing the mass of the empirical formula with the molar mass. (Section 3.5)

Solve To determine the empirical formula, we assume we have a 100-g sample and calculate the number of moles of each element in the sample:

$$\text{Moles C} = (46.2\ \cancel{\text{g C}})\left(\frac{1\text{ mol C}}{12.01\ \cancel{\text{g C}}}\right) = 3.85\text{ mol C}$$

$$\text{Moles N} = (53.8\ \cancel{\text{g N}})\left(\frac{1\text{ mol N}}{14.01\ \cancel{\text{g N}}}\right) = 3.84\text{ mol N}$$

Continued

Because the ratio of the moles of the two elements is essentially 1:1, the empirical formula is CN. To determine the molar mass, we use Equation 10.11.

$$\mathcal{M} = \frac{dRT}{P} = \frac{(1.05\ \text{g}/0.500\ \cancel{\text{L}})(0.08206\ \cancel{\text{L-atm}}/\text{mol-}\cancel{\text{K}})(298\ \cancel{\text{K}})}{(751/760)\ \cancel{\text{atm}}}$$

$$= 52.0\ \text{g/mol}$$

The molar mass associated with the empirical formula CN is $12.0 + 14.0 = 26.0\ \text{g/mol}$. Dividing the molar mass by that of its empirical formula gives $(52.0\ \text{g/mol})/(26.0\ \text{g/mol}) = 2.00$. Thus, the molecule has twice as many atoms of each element as the empirical formula, giving the molecular formula C_2N_2.

(**b**) **Plan** To determine the molecular structure, we must first determine the Lewis structure. (Section 8.5) We can then use the VSEPR model to predict the structure. (Section 9.2)

Solve The molecule has $2(4) + 2(5) = 18$ valence-shell electrons. By trial and error, we seek a Lewis structure with 18 valence electrons in which each atom has an octet and the formal charges are as low as possible. The structure

$$:\text{N}\equiv\text{C}-\text{C}\equiv\text{N}:$$

meets these criteria. (This structure has zero formal charge on each atom.)

The Lewis structure shows that each atom has two electron domains. (Each nitrogen has a nonbonding pair of electrons and a triple bond, whereas each carbon has a triple bond and a single bond.) Thus, the electron-domain geometry around each atom is linear, causing the overall molecule to be linear.

(**c**) **Plan** To determine the polarity of the molecule, we must examine the polarity of the individual bonds and the overall geometry of the molecule.

Solve Because the molecule is linear, we expect the two dipoles created by the polarity in the carbon–nitrogen bond to cancel each other, leaving the molecule with no dipole moment.

Chapter Summary and Key Terms

PHYSICAL CHARACTERISTICS OF GASES (SECTION 10.1) Substances that are gases at room temperature tend to be molecular substances with low molar masses. Air, a mixture composed mainly of N_2 and O_2, is the most common gas we encounter. Some liquids and solids can also exist in the gaseous state, where they are known as **vapors**. Gases are compressible; they mix in all proportions because their component molecules are far apart from each other. To describe the state or condition of a gas, we must specify four variables: pressure (P), volume (V), temperature (T), and quantity (n). Volume is usually measured in liters, temperature in kelvins, and quantity of gas in moles. **Pressure** is the force per unit area and is expressed in SI units as **pascals**, Pa ($1\ \text{Pa} = 1\ \text{N/m}^2$). A related unit, the **bar**, equals 10^5 Pa. In chemistry, **standard atmospheric pressure** is used to define the **atmosphere** (atm) and the **torr** (also called the millimeter of mercury). One atmosphere of pressure equals 101.325 kPa, or 760 torr. A barometer is often used to measure the atmospheric pressure. A manometer can be used to measure the pressure of enclosed gases.

THE GAS LAWS (SECTION 10.2) Studies have revealed several simple gas laws: For a constant quantity of gas at constant temperature, the volume of the gas is inversely proportional to the pressure (**Boyle's law**). For a fixed quantity of gas at constant pressure, the volume is directly proportional to its absolute temperature (**Charles's law**). Equal volumes of gases at the same temperature and pressure contain equal numbers of molecules (**Avogadro's hypothesis**). For a gas at constant temperature and pressure, the volume of the gas is directly proportional to the number of moles of gas (**Avogadro's law**). Each of these gas laws is a special case of the ideal-gas equation.

THE IDEAL-GAS EQUATION (SECTION 10.3) The **ideal-gas equation**, $PV = nRT$, is the equation of state for an **ideal gas**. The term R in this equation is the **gas constant**. We can use the ideal-gas equation to calculate variations in one variable when one or more of the others are changed. Most gases at pressures less than 10 atm and temperatures near 273 K and above obey the ideal-gas equation reasonably well. The conditions of 273 K (0 °C) and 1 atm are known as the **standard temperature and pressure (STP)**. In all applications of the ideal-gas equation, we must remember to convert temperatures to the absolute-temperature scale (the Kelvin scale).

Using the ideal-gas equation, we can relate the density of a gas to its molar mass: $\mathcal{M} = dRT/P$. We can also use the ideal-gas equation to solve problems involving gases as reactants or products in chemical reactions.

GAS MIXTURES AND PARTIAL PRESSURES (SECTION 10.4) In gas mixtures, the total pressure is the sum of the **partial pressures** that each gas would exert if it were present alone under the same conditions (**Dalton's law of partial pressures**). The partial pressure of a component of a mixture is equal to its mole fraction times the total pressure: $P_1 = X_1P_t$. The **mole fraction** X is the ratio of the moles of one component of a mixture to the total moles of all components.

THE KINETIC-MOLECULAR THEORY OF GASES (SECTION 10.5) The **kinetic-molecular theory of gases** accounts for the properties of an ideal gas in terms of a set of statements about the nature of gases. Briefly, these statements are as follows: (1) Molecules are in continuous chaotic motion; (2) The volume of gas molecules is negligible compared to the volume of their container; (3) The gas molecules neither attract nor repel each other; (4) The average kinetic energy of the gas molecules is proportional to the absolute temperature and does not change if the temperature remains constant.

The individual molecules of a gas do not all have the same kinetic energy at a given instant. Their speeds are distributed over a wide range; the distribution varies with the molar mass of the gas and with temperature.

MOLECULAR SPEEDS, EFFUSION, AND DIFFUSION (SECTION 10.6) Gas molecules are in constant motion. Their **root-mean-square (rms) speed**, u_{rms}, varies in proportion to the square root of the absolute temperature and inversely with the square root of the molar mass: $u_{\text{rms}} = \sqrt{(3RT/\mathcal{M})}$. The most probable speed of a gas molecule is given by $u_{\text{mp}} = \sqrt{(2RT/\mathcal{M})}$. The average speed of a gas molecule is given by $u_{\text{av}} = \sqrt{(8RT/\pi\mathcal{M})}$.

It follows from kinetic-molecular theory that the rate at which a gas undergoes **effusion** (escapes through a tiny hole) is inversely proportional to the square root of its molar mass (**Graham's law**). The **diffusion** of gas molecules through space is another phenomenon related to the speeds at which molecules move. Because moving molecules undergo frequent collisions with one another, the **mean free path**—the mean distance traveled between collisions—is short. Collisions between molecules limit the rate at which a gas molecule can diffuse.

REAL GASES: DEVIATIONS FROM IDEAL BEHAVIOR (SECTION 10.7) Departures from ideal behavior increase in magnitude as pressure increases and as temperature decreases. Real gases depart from ideal behavior because (1) the molecules possess finite volume and (2) the molecules experience attractive forces for one another. These two effects make the volumes of real gases larger and their pressures smaller than those of an ideal gas. The **van der Waals equation** is an equation of state for gases, which modifies the ideal-gas equation to account for intrinsic molecular volume and intermolecular forces.

Key Equations

$PV = nRT$	[10.5]	Ideal-gas equation
$\frac{P_1V_1}{T_1} = \frac{P_2V_2}{T_2}$	[10.8]	The combined gas law, showing how *P*, *V*, and *T* are related for a constant *n*
$d = \frac{P\mathcal{M}}{RT}$	[10.10]	Density or molar mass of an ideal gas
$P_t = P_1 + P_2 + P_3 + \ldots$	[10.12]	Relating the total pressure of a gas mixture to the partial pressures of its components (Dalton's law of partial pressures)
$P_1 = \left(\frac{n_1}{n_t}\right)P_t = X_1P_t$	[10.16]	Relating partial pressure to mole fraction
$u_{\text{rms}} = \sqrt{\frac{3RT}{\mathcal{M}}}$	[10.20]	Definition of the root-mean-square (rms) speed of gas molecules
$u_{\text{mp}} = \sqrt{\frac{2RT}{\mathcal{M}}}$	[10.21]	Definition of the most probably (mp) speed of gas molecules
$u_{\text{av}} = \sqrt{\frac{8RT}{\pi\mathcal{M}}}$	[10.22]	Definition of the average (av) speed of gas molecules
$\frac{r_1}{r_2} = \sqrt{\frac{\mathcal{M}_2}{\mathcal{M}_1}}$	[10.24]	Relating the relative rates of effusion of two gases to their molar masses
$\left(P + \frac{n^2a}{V^2}\right)(V - nb) = nRT$	[10.26]	The van der Waals equation

Exam Prep

EP 10.1 Which statement about gases is false? (**a**) A given gas can mix in all proportions with any other gas. (**b**) Gases are incompressible. (**c**) Gaseous substances can be atomic or molecular. (**d**) Substances that are gases at room temperature generally have molar masses lower than 100 g/mol.

EP 10.2 What would be the height of the column in a barometer if the external pressure was 101 kPa and water ($d = 1.00\ \text{g/cm}^3$) was used in place of mercury ($d = 13.6\ \text{g/cm}^3$)? (**a**) 0.0558 m (**b**) 0.760 m (**c**) 1.03×10^4 m (**d**) 10.3 m (**e**) 0.103 m

EP 10.3 If the gas inside the flask in Figure 10.3 is cooled so that its pressure is reduced to a value of 715.7 torr, what will be the height of the mercury in the open-ended arm? (*Hint:* The sum of the heights in both arms must remain constant regardless of the change in pressure.) (**a**) 49.0 mm (**b**) 95.6 mm (**c**) 144.6 mm (**d**) 120.1 mm

EP 10.4 The deepest place on Earth is 7 miles below sea level in the Pacific Ocean's Mariana Trench. The water pressure at the bottom of the Trench is reported to be a bone-crushing 8 tons per square inch. Convert this value to atmospheres ($1\ \text{atm} = 14.70\ \text{lb/in}^2$; 1 ton = 2000 lbs). (**a**) 0.004 atm (**b**) 0.06 atm (**c**) 100 atm (**d**) 1000 atm (**e**) 2×10^4 atm

EP 10.5 Which of the following statements is or are *true* for an ideal gas?

- (**i**) The volume occupied by the molecules is negligible.
- (**ii**) The molecules are all moving at the same speed.
- (**iii**) The molecules are neither attracted to nor repelled from each other.

(**a**) Only one of these statements is true. (**b**) i and ii (**c**) i and iii (**d**) ii and iii (**e**) All three statements are true.

EP 10.6 Which statement about gas behavior is *true*? (**a**) If you increase the pressure of a fixed amount of gas while keeping the temperature constant, the volume must increase. (**b**) If you increase the amount of a gas while holding the pressure and temperature constant, the volume must decrease. (**c**) If you plot *V* versus 1/*P* for a fixed quantity of a gas at constant temperature, you will get a straight line with a positive slope. (**d**) If you plot *V* versus 1/*n* for a gas at constant *T* and *P*, you will get a straight line with a positive slope.

EP 10.7 If you double the number of moles of an ideal gas in a fixed volume while keeping the temperature constant, what happens to the pressure? (**a**) It doubles. (**b**) It remains the same. (**c**) It is decreased by a factor of 2. (**d**) It is increased by a factor of 4. (**e**) It is decreased by a factor of 4.

EP 10.8 A sample of oxygen gas with a mass of 8.0 g is added to a cylinder equipped with massless and frictionless piston. If the apparatus is placed in a chamber where the temperature is 0 °C and the pressure is 1.0 atm, the gas will occupy a volume of 5.6 L. If the pressure inside the chamber is increased to 3.0 atm, the piston will shift until the gas occupies a volume of ______. (**a**) 17 L (**b**) 1.9 L (**c**) 22.4 L (**d**) 0.62 L

EP 10.9 A helium balloon is filled to a volume of 5.60 L at 25 °C. What will the volume of the balloon become if it is put into liquid nitrogen to lower the temperature of the helium to 77 K? (**a**) 17 L (**b**) 22 L (**c**) 1.4 L (**d**) 0.046 L (**e**) 3.7 L

EP 10.10 The Goodyear blimp contains 5.74×10^6 L of helium at 25.0 °C and 1.00 atm. What is the mass in grams of the helium inside the blimp?

(**a**) 2.30×10^7 g
(**b**) 2.80×10^6 g
(**c**) 1.12×10^7 g
(**d**) 2.34×10^5 g
(**e**) 9.39×10^5 g

EP 10.11 If you fill your car tire to a pressure of 32 psi (pounds per square inch) on a hot summer day when the temperature is 35 °C (95 °F), what is the pressure (in psi) on a cold winter day when the temperature is −15 °C (5 °F)? Assume no gas leaks out between measurements and the volume of the tire does not change. (**a**) 38 psi (**b**) 27 psi (**c**) 1.8 psi (**d**) 13.7 psi

EP 10.12 A gas occupies a volume of 0.75 L at 20 °C at 720 torr. What volume would the gas occupy at 41 °C and 760 torr? (**a**) 1.45 L (**b**) 0.85 L (**c**) 0.76 L (**d**) 0.66 L (**e**) 0.35 L

EP 10.13 What is the density of methane, CH_4, in a vessel where the pressure is 910 torr and the temperature is 255 K? (**a**) 0.92 g/L (**b**) 697 g/L (**c**) 0.057 g/L (**d**) 16 g/L (**e**) 0.72 g/L

EP 10.14 What is the molar mass of an unknown hydrocarbon whose density is measured to be 1.97 g/L at STP? (**a**) 4.04 g/mol (**b**) 30.7 g/mol (**c**) 44.1 g/mol (**d**) 48.2 g/mol

EP 10.15 Silver oxide decomposes when heated:

$$2\ Ag_2O(s) \xrightarrow{\Delta} 4\ Ag(s) + O_2(g)$$

If 5.76 g of Ag_2O is heated and the O_2 gas produced by the reaction is collected in an evacuated flask, what is the pressure of the O_2 gas if the volume of the flask is 0.65 L and the gas temperature is 25 °C? (**a**) 0.94 atm (**b**) 0.039 atm (**c**) 0.012 atm (**d**) 0.47 atm (**e**) 3.2 atm

EP 10.16 A 15-L cylinder contains 4.0 g of hydrogen and 28 g of nitrogen. If the temperature is 27 °C, what is the total pressure of the mixture? (**a**) 0.44 atm (**b**) 1.6 atm (**c**) 3.3 atm (**d**) 4.9 atm (**e**) 9.8 atm

EP 10.17 A 4.0-L vessel containing N_2 at STP and a 2.0-L vessel containing H_2 at STP are connected by a valve. If the valve is opened allowing the two gases to mix, what is the mole fraction of hydrogen in the mixture? (**a**) 0.034 (**b**) 0.33 (**c**) 0.50 (**d**) 0.67 (**e**) 0.96

EP 10.18 Consider two gas cylinders of the same volume and temperature, one containing 1.0 mol of propane, C_3H_8, and the other 2.0 mol of methane, CH_4. Which of the following statements is *true*? (**a**) The C_3H_8 and CH_4 molecules have the same u_{rms}. (**b**) The C_3H_8 and CH_4 molecules have the same average kinetic energy. (**c**) The rate at which the molecules collide with the cylinder walls is the same for both cylinders. (**d**) The gas pressure is the same in both cylinders.

EP 10.19 Which of these is *not* an assumption of the kinetic-molecular theory of gases? (**a**) Gas molecules take up no space. (**b**) Gas molecules move in circles. (**c**) The average kinetic energy of the gas molecules is proportional to temperature. (**d**) Gas molecules neither attract nor repel each other. (**e**) Gas molecules are in constant motion.

EP 10.20 Fill in the blanks for the following statement: The rms speed of the molecules in a sample of H_2 gas at 300 K will be ____ times larger than the rms speed of O_2 molecules at the same temperature, and the ratio _____ with increasing temperature. (**a**) four, will not change (**b**) four, will increase (**c**) sixteen, will not change (**d**) sixteen, will decrease (**e**) Not enough information is given to answer this question.

EP 10.21 Calculate the average speed of CO_2 molecules at −40.0 °C, the typical temperature of an airplane flying at 36,000 ft. (**a**) 10.6 m/s (**b**) 33.3 m/s (**c**) 297 m/s (**d**) 335 m/s (**e**) 364 m/s

EP 10.22 Which of the following changes will lead to an increase in the mean free path of the molecules of gas in a closed container?

- (**i**) Lower the temperature without changing the volume of the container.
- (**ii**) Increase the volume of the container without changing the temperature.
- (**iii**) Open the valve on the container to release half of the molecules without changing the temperature or volume of the container.

(**a**) Only i (**b**) only ii (**c**) only iii (**d**) both ii and iii (**e**) all three

EP 10.23 In a system for separating gases, a tank containing a mixture of hydrogen and carbon dioxide is connected to a much larger tank where the pressure is kept very low. The two tanks are separated by a porous membrane through which the molecules must effuse. If the initial partial pressure of each gas is 5.00 atm, what will be the mole fraction of hydrogen in the tank after the partial pressure of carbon dioxide has declined to 4.50 atm? (**a**) 52.1% (**b**) 37.2% (**c**) 32.1% (**d**) 4.68% (**e**) 27.4%

EP 10.24 Calculate the pressure of a 2.975-mol sample of N_2 in a 0.7500-L flask at 300.0 °C using the van der Waals equation and then repeat the calculation using the ideal-gas equation. Within the limits of the significant figures justified by these parameters, will the ideal-gas equation overestimate or underestimate the pressure, and if so by how much?

(**a**) Underestimate by 12.38 atm

(**b**) Overestimate by 12.38 atm

(**c**) Underestimate by 3.85 atm

(**d**) Overestimate by 3.85 atm

EP 10.25 Which of the following statements regarding deviations from ideal-gas behavior are *true*?

- (**i**) Gases behave nonideally because most molecules aren't spherical.
- (**ii**) Gases behave nonideally because atoms and molecules occupy finite volumes.
- (**iii**) Gases behave nonideally because atoms and molecules attract one another.
- (**iv**) Gases will behave most ideally under conditions of high temperature and low pressure.

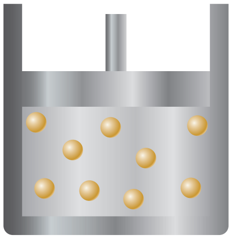
(**a**) i and ii (**b**) ii and iii (**c**) iii and iv (**d**) i, ii, and iii (**e**) ii, iii, and iv

Exercises

Visualizing Concepts

10.1 Mars has an average atmospheric pressure of 0.007 atm. Would it be easier or harder to drink from a straw on Mars than on Earth? Explain. [Section 10.1]

10.2 You have a sample of gas in a container with a movable piston, such as the one in the drawing. (**a**) Redraw the container to show what it might look like if the temperature of the gas is increased from 300 to 500 K while the pressure is kept constant. (**b**) Redraw the container to show what it might look like if the external pressure on the piston is increased from 1.0 atm to 2.0 atm while the temperature is kept constant. (**c**) Redraw the container to show what it might look like if the temperature of the gas decreases from 300 to 200 K while the pressure is kept constant (assume the gas does not liquefy). [Section 10.2]



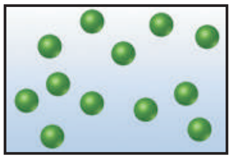
10.3 Consider the sample of gas depicted here. What would the drawing look like if the volume and temperature remained constant while you removed enough of the gas to decrease the pressure by a factor of 2? [Section 10.2]

(**a**) It would contain the same number of molecules.

(**b**) It would contain half as many molecules.

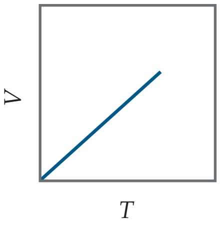
(**c**) It would contain twice as many molecules.

(**d**) There is insufficient data to say.

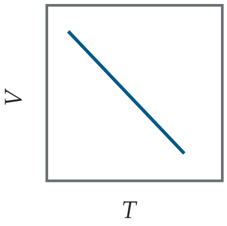


10.4 Imagine that the reaction $2\,CO(g) + O_2(g) \longrightarrow 2\,CO_2(g)$ occurs in a container that has a piston that moves to maintain a constant pressure when the reaction occurs at constant temperature. Which of the following statements describes how the volume of the container changes due to the reaction: (**a**) The volume increases by 50%. (**b**) The volume increases by 33%. (**c**) The volume remains constant. (**d**) The volume decreases by 33%. (**e**) The volume decreases by 50%. [Section 10.3]

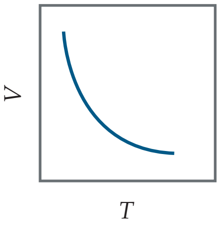
10.5 Consider a fixed quantity of gas at constant pressure. If the volume of the gas is plotted as the temperature is changed, which of the following plots will be obtained? [Section 10.3]



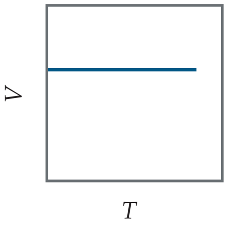
(a)



(b)



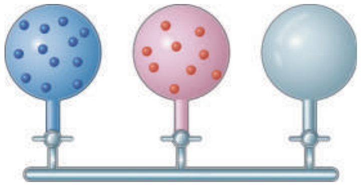
(c)



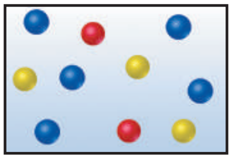
(d)

(e) None of the above

10.6 The apparatus shown here has two gas-filled containers and one empty container, all attached to a hollow horizontal tube closed at both ends. (**a**) How many blue gas molecules are in the left container? (**b**) How many red gas molecules are in the middle container? (**c**) When the valves are opened and the gases are allowed to mix at constant temperature, how many atoms of each type of gas end up in the originally empty container? Assume that the containers are of equal volume and ignore the volume of the connecting tube. [Section 10.4]

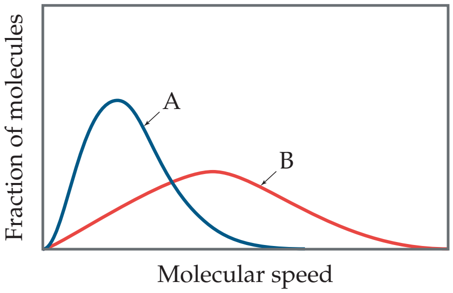


10.7 The accompanying drawing represents a mixture of three different gases. (**a**) Rank the three components (red, yellow, blue) in order of increasing partial pressure. (**b**) If the total pressure of the mixture is 1.40 atm, calculate the partial pressure of each gas. [Section 10.4]

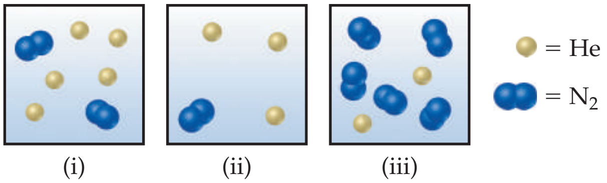


10.8 On a single plot, qualitatively sketch the distribution of molecular speeds for (**a**) Kr(*g*) at $-50\,^\circ C$, (**b**) Kr(*g*) at $0\,^\circ C$, (**c**) Ar(*g*) at $0\,^\circ C$. [Section 10.6]

10.9 Consider the following graph. (**a**) If curves A and B refer to two different gases, He and O_2, at the same temperature, which curve corresponds to He? (**b**) If A and B refer to the same gas at two different temperatures, which represents the higher temperature? (**c**) For each curve, which speed is highest: the most probable speed, the root-mean-square speed, or the average speed? [Section 10.6]

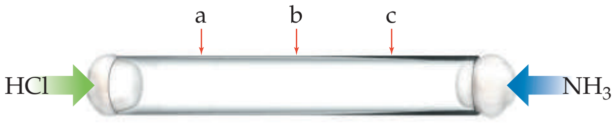


10.10 Consider the following samples of gases:

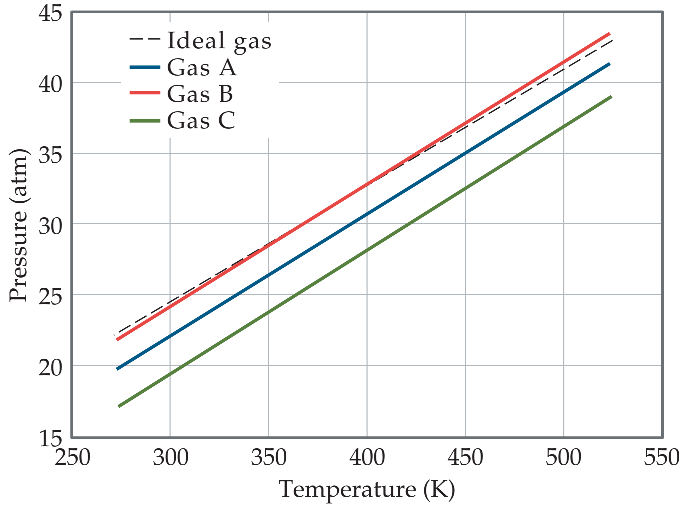


If the three samples are all at the same temperature, rank them with respect to (**a**) total pressure, (**b**) partial pressure of helium, (**c**) density, (**d**) average kinetic energy of particles. [Sections 10.5 and 10.6]

10.11 A thin glass tube 1 m long is filled with Ar gas at 1 atm, and the ends are stoppered with cotton plugs as shown in the drawing. HCl gas is introduced at one end of the tube, and simultaneously NH_3 gas is introduced at the other end. When the two gases diffuse through the cotton plugs down the tube and meet, a white ring appears due to the formation of $NH_4Cl(s)$. At which location—a, b, or c—do you expect the ring to form? [Section 10.6]



10.12 The graph provided shows the change in pressure as the temperature increases for a 1-mol sample of a gas confined to a 1-L container. The four plots correspond to an ideal gas and three real gases: CO_2, N_2, and Cl_2. (**a**) At room temperature, all three real gases have a pressure less than the ideal gas. Which van der Waals constant, *a* or *b*, accounts for the influence intermolecular forces have in lowering the pressure of a real gas? (**b**) Use the van der Waals constants in Table 10.3 to match the labels in the plot (A, B, and C) with the respective gases (CO_2, N_2, and Cl_2). [Section 10.7]



Physical Characteristics of Gases (Section 10.1)

10.13 Which of the following statements is *false*?

(**a**) Gases are far less dense than liquids.

(**b**) Gases are far more compressible than liquids.

(**c**) Because liquid water and liquid carbon tetrachloride do not mix, neither do their vapors.

(**d**) The volume occupied by a gas is determined by the volume of its container.

10.14 (**a**) Are you more likely to see the density of a gas reported in g/mL, g/L, or kg/cm^3? (**b**) Which units are appropriate for expressing atmospheric pressures: N, Pa, atm, kg/m^2? (**c**) Which is most likely to be a gas at room temperature and ordinary atmospheric pressure: F_2, Br_2, K_2O.

10.15 Suppose that a woman weighing 130 lb and wearing high-heeled shoes momentarily places all her weight on the heel of one foot. If the area of the heel is 0.50 in.^2, calculate the pressure exerted on the underlying surface in (**a**) pounds per square inch, (**b**) kilopascals, and (**c**) atmospheres.

10.16 A set of bookshelves rests on a hard floor surface on four legs, each having a cross-sectional dimension of 3.0×4.1 cm in contact with the floor. The total mass of the shelves plus the books stacked on them is 262 kg. Calculate the pressure in pascals exerted by the shelf footings on the surface.

10.17 (**a**) How high in meters must a column of glycerol be to exert a pressure equal to that of a 760-mm column of mercury? The density of glycerol is 1.26 g/mL, whereas that of mercury is 13.6 g/mL. (**b**) What pressure, in atmospheres, is exerted on the body of a diver if they are 15 ft below the surface of the water when the atmospheric pressure is 750 torr? Assume that the density of the water is $1.00 \text{ g/cm}^3 = 1.00 \times 10^3 \text{ kg/m}^3$. The gravitational constant is 9.81 m/s^2, and $1 \text{ Pa} = 1 \text{ kg/m-s}^2$.

10.18 (**a**) The compound 1-iodododecane is a nonvolatile liquid with a density of 1.20 g/mL. The density of mercury is 13.6 g/mL. What do you predict for the height of a barometer column based on 1-iodododecane, when the atmospheric pressure is 749 torr? (**b**) What is the pressure, in atmospheres, on the body of a diver if they are 21 ft below the surface of the water when the atmospheric *pressure* is 742 torr?

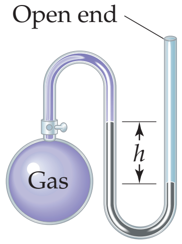
10.19 The typical atmospheric pressure on top of Mount Everest (29,032 ft) is about 265 torr. Convert this pressure to (**a**) atm, (**b**) mm Hg, (**c**) pascals, (**d**) bars, (**e**) psi.

10.20 Perform the following conversions: (**a**) 0.912 atm to torr, (**b**) 0.685 bar to kilopascals, (**c**) 655 mm Hg to atmospheres, (**d**) 1.323×10^5 Pa to atmospheres, (**e**) 2.50 atm to psi.

10.21 In the United States, barometric pressures are generally reported in inches of mercury (in. Hg). On a beautiful summer day in Chicago, the barometric pressure is 30.45 in. Hg. (**a**) Convert this pressure to torr. (**b**) Convert this pressure to atm.

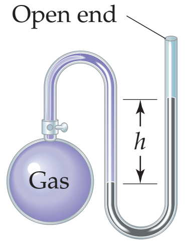
10.22 Hurricane Wilma of 2005 is the most intense hurricane on record in the Atlantic basin, with a low-pressure reading of 882 mbar (millibars). Convert this reading into (**a**) atmospheres, (**b**) torr, and (**c**) inches of Hg.

10.23 If the atmospheric pressure is 0.995 atm, what is the pressure of the enclosed gas in each of the three cases depicted in the drawing? Assume that the gray liquid is mercury.



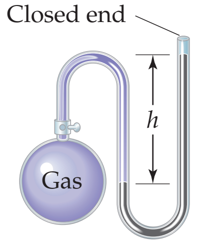
$h = 52$ cm

(i)



$h = 67$ cm

(ii)



$h = 10.3$ cm

(iii)

10.24 An open-end manometer containing mercury is connected to a container of gas, as depicted in Sample Exercise 10.2. What is the pressure of the enclosed gas in torr in each of the following situations? (**a**) The mercury in the arm attached to the gas is 15.4 mm higher than in the one open to the atmosphere; atmospheric pressure is 0.985 atm. (**b**) The mercury in the arm attached to the gas is 12.3 mm lower than in the one open to the atmosphere; atmospheric pressure is 0.99 atm.

The Gas Laws (Section 10.2)

10.25 You have a gas at 25 °C confined to a cylinder with a movable piston. Which of the following actions would double the gas pressure? (**a**) Lifting up on the piston to double the volume while keeping the temperature constant; (**b**) Heating the gas so that its temperature rises from 25 °C to 50 °C, while keeping the volume constant; (**c**) Pushing down on the piston to halve the volume while keeping the temperature constant.

10.26 A fixed quantity of gas at 21 °C exhibits a pressure of 752 torr and occupies a volume of 5.12 L. (**a**) Calculate the volume the gas will occupy if the pressure is increased to 1.88 atm while the temperature is held constant. (**b**) Calculate the volume the gas will occupy if the temperature is increased to 175 °C while the pressure is held constant.

10.27 (**a**) Amonton's law expresses the relationship between pressure and temperature. Use Charles's law and Boyle's law to derive the proportionality relationship between *P* and *T*. (**b**) If a car tire is filled to a pressure of 32.0 lb/in.^2 (psi) measured at 75 °F, what will be the tire pressure if the tires heat up to 120 °F during driving?

10.28 Nitrogen and hydrogen gases react to form ammonia gas as follows:

$$N_2(g) + 3\,H_2(g) \longrightarrow 2\,NH_3(g)$$

At a certain temperature and pressure, 1.2 L of N_2 reacts with 3.6 L of H_2. If all the N_2 and H_2 are consumed, what volume of NH_3, at the same temperature and pressure, will be produced?

The Ideal-Gas Equation (Section 10.3)

10.29 (**a**) What conditions are represented by the abbreviation STP? (**b**) What is the molar volume of an ideal gas at STP? (**c**) Room temperature is often assumed to be 25 °C. Calculate the molar volume of an ideal gas at 25 °C and 1 atm pressure. (**d**) If you measure pressure in bars instead of atmospheres, calculate the corresponding value of R in L-bar/mol-K.

10.30 To derive the ideal-gas equation, we assume that the volume of the gas atoms/molecules can be neglected. Given the atomic radius of neon, 0.69 Å, and knowing that a sphere has a volume of $4\pi r^3/3$, calculate the fraction of space that Ne atoms occupy in a sample of neon at STP.

10.31 Suppose you are given two 1-L flasks and told that one contains a gas of molar mass 30 and the other a gas of molar mass 60, both at the same temperature. The pressure in flask A is x atm, and the mass of gas in the flask is 1.2 g. The pressure in flask B is $0.5x$ atm, and the mass of gas in that flask is 1.2 g. Which flask contains the gas of molar mass 30, and which contains the gas of molar mass 60?

10.32 Suppose you are given two flasks at the same temperature, one of volume 2 L and the other of volume 3 L. The 2-L flask contains 4.8 g of gas, and the gas pressure is x atm. The 3-L flask contains 0.36 g of gas, and the gas pressure is $0.1x$. Do the two gases have the same molar mass? If not, which contains the gas of higher molar mass?

10.33 Complete the following table for an ideal gas:

P	V	n	T
2.00 atm	1.00 L	0.500 mol	? K
0.300 atm	0.250 L	? mol	27 °C
650 torr	? L	0.333 mol	350 K
? atm	585 mL	0.250 mol	295 K

10.34 Calculate each of the following quantities for an ideal gas: (**a**) the volume of the gas, in liters, if 1.50 mol has a pressure of 1.25 atm at a temperature of −6 °C; (**b**) the absolute temperature of the gas at which 3.33×10^{-3} mol occupies 478 mL at 750 torr; (**c**) the pressure, in atmospheres, if 0.00245 mol occupies 413 mL at 138 °C; (**d**) the quantity of gas, in moles, if 126.5 L at 54 °C has a pressure of 11.25 kPa.

10.35 The Goodyear blimps, which frequently fly over sporting events, hold approximately 175,000 ft^3 of helium. If the gas is at 23 °C and 1.0 atm, what mass of helium is in a blimp?

10.36 A neon sign is made of glass tubing whose inside diameter is 2.5 cm and whose length is 5.5 m. If the sign contains neon at a pressure of 1.78 torr at 35 °C, how many grams of neon are in the sign? (The volume of a cylinder is $\pi r^2 h$.)

10.37 (**a**) Calculate the number of molecules in a deep breath of air whose volume is 2.25 L at body temperature, 37 °C, and a pressure of 735 torr. (**b**) The adult blue whale has a lung capacity of 5.0×10^3 L. Calculate the mass of air (assume an average molar mass of 28.98 g/mol) contained in an adult blue whale's lungs at 0.0 °C and 1.00 atm, assuming the air behaves ideally.

10.38 (**a**) If the pressure exerted by ozone, O_3, in the stratosphere is 3.0×10^{-3} atm and the temperature is 250 K, how many ozone molecules are in a liter? (**b**) Carbon dioxide makes up approximately 0.04% of Earth's atmosphere. If you collect a 2.0-L sample from the atmosphere at sea level (1.00 atm) on a warm day (27 °C), how many CO_2 molecules are in your sample?

10.39 A scuba diver's tank contains 0.29 kg of O_2 compressed into a volume of 2.3 L. (**a**) Calculate the gas pressure inside the tank at 9 °C. (**b**) What volume would this oxygen occupy at 26 °C and 0.95 atm?

10.40 An aerosol spray can with a volume of 250 mL contains 2.30 g of propane gas (C_3H_8) as a propellant. (**a**) If the can is at 23 °C, what is the pressure in the can? (**b**) What volume would the propane occupy at STP? (**c**) The can's label says that exposure to temperatures above 130 °F may cause the can to burst. What is the pressure in the can at this temperature?

10.41 A 35.1 g sample of solid CO_2 (dry ice) is added to a container at a temperature of 100 K with a volume of 4.0 L. If the container is evacuated (all of the gas is removed), sealed, and then allowed to warm to room temperature ($T = 298$ K) so that all of the solid CO_2 is converted to a gas, what is the pressure inside the container?

10.42 A 334-mL cylinder for use in chemistry lectures contains 5.225 g of helium at 23 °C. How many grams of helium must be released to reduce the pressure to 75 atm assuming ideal-gas behavior?

10.43 Chlorine is widely used to purify municipal water supplies and to treat swimming pool waters. Suppose that the volume of a particular sample of Cl_2 gas is 8.70 L at 895 torr and 24 °C. (**a**) How many grams of Cl_2 are in the sample? (**b**) What volume will the Cl_2 occupy at STP? (**c**) At what temperature will the volume be 15.00 L if the pressure is 8.76×10^2 torr? (**d**) At what pressure will the volume equal 5.00 L if the temperature is 58 °C?

10.44 Many gases are shipped in high-pressure containers. Consider a steel tank whose volume is 55.0 gallons that contains O_2 gas at a pressure of 16,500 kPa at 23 °C. (**a**) What mass of O_2 does the tank contain? (**b**) What volume would the gas occupy at STP? (**c**) At what temperature would the pressure in the tank equal 150.0 atm? (**d**) What would be the pressure of the gas, in kPa, if it were transferred to a container at 24 °C whose volume is 55.0 L?

10.45 In an experiment reported in the scientific literature, male cockroaches were made to run at different speeds on a miniature treadmill while their oxygen consumption was measured. In 1 h the average cockroach running at 0.08 km/h consumed 0.8 mL of O_2 at 1 atm pressure and 24 °C per gram of insect mass. (**a**) How many moles of O_2 would be consumed in 1 h by a 5.2-g cockroach moving at this speed? (**b**) This same cockroach is caught by a child and placed in a 1-qt fruit jar with a tight lid. Assuming the same level of continuous activity as in the research, will the cockroach consume more than 20% of the available O_2 in a 48-h period? (Air is 21 mol% O_2.)

10.46 The physical fitness of athletes is measured by "V_{O_2} max," which is the maximum volume of oxygen consumed by an individual during incremental exercise (for example, on a treadmill). An average male has a V_{O_2} max of 45 mL O_2/kg body mass/min, but a world-class male athlete can have a V_{O_2} max reading of 88.0 mL O_2/kg body mass/min. (**a**) Calculate the volume of oxygen, in mL, consumed in 1 h by an average man who weighs 185 lb and has a V_{O_2} max reading of 47.5 mL O_2/kg body mass/min. (**b**) If this man lost 20 lb, exercised, and increased his V_{O_2} max to 65.0 mL O_2/kg body mass/min, how many mL of oxygen would he consume in 1 h?

10.47 Rank the following gases from least dense to most dense at 1.00 atm and 298 K: CO, N_2O, Cl_2, HF.

10.48 Rank the following gases from least dense to most dense at 1.00 atm and 298 K: SO_2, HBr, CO_2.

10.49 Which of the following statements best explains why a closed balloon filled with helium gas rises in air?

(**a**) Helium is a monatomic gas, whereas nearly all the molecules that make up air, such as nitrogen and oxygen, are diatomic.

(**b**) The average speed of helium atoms is greater than the average speed of air molecules, and the greater speed of collisions with the balloon walls propels the balloon upward.

(**c**) Because the helium atoms are of lower mass than the average air molecule, the helium gas is less dense than air. The mass of the balloon is thus less than the mass of the air displaced by its volume.

(**d**) Because helium has a lower molar mass than the average air molecule, the helium atoms are in faster motion. This means that the temperature of the helium is greater than the air temperature. Hot gases tend to rise.

10.50 Which of the following statements best explains why nitrogen gas at STP is less dense than Xe gas at STP?

(**a**) Because Xe is a noble gas, there is less tendency for the Xe atoms to repel one another, so they pack more densely in the gaseous state.

(**b**) Xe atoms have a higher mass than N_2 molecules. Because both gases at STP have the same number of molecules per unit volume, the Xe gas must be denser.

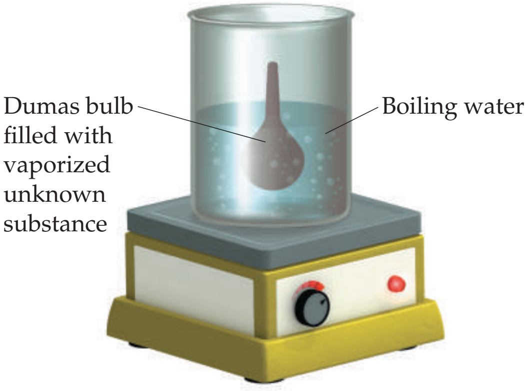
(**c**) The Xe atoms are larger than N_2 molecules and thus take up a larger fraction of the space occupied by the gas.

(**d**) Because the Xe atoms are much more massive than the N_2 molecules, they move more slowly and thus exert less upward force on the gas container and make the gas appear denser.

10.51 (**a**) Calculate the density of NO_2 gas at 0.970 atm and 35 °C. (**b**) Calculate the molar mass of a gas if 2.50 g occupies 0.875 L at 685 torr and 35 °C.

10.52 (**a**) Calculate the density of sulfur hexafluoride gas at 707 torr and 21 °C. (**b**) Calculate the molar mass of a vapor that has a density of 7.135 g/L at 12 °C and 743 torr.

10.53 In the Dumas-bulb technique for determining the molar mass of an unknown liquid, you vaporize the sample of a liquid that boils below 100 °C in a boiling-water bath and determine the mass of vapor required to fill the bulb. From the following data, calculate the molar mass of the unknown liquid: mass of unknown vapor, 1.012 g; volume of bulb, 354 cm^3; pressure, 742 torr; temperature, 99 °C.



Dumas bulb filled with vaporized unknown substance
Boiling water

10.54 The molar mass of a volatile substance was determined by the Dumas-bulb method described in Exercise 10.53. The unknown vapor had a mass of 0.846 g; the volume of the bulb was 354 cm^3, pressure 752 torr, and temperature 100 °C. Calculate the molar mass of the unknown vapor.

10.55 Magnesium can be used as a "getter" in evacuated enclosures to react with the last traces of oxygen. (The magnesium is usually heated by passing an electric current through a wire or ribbon of the metal.) If an enclosure of 0.452 L has a partial pressure of O_2 of 3.5×10^{-6} torr at 27 °C, what mass of magnesium will react according to the following equation?

$$2\,Mg(s) + O_2(g) \longrightarrow 2\,MgO(s)$$

10.56 Calcium hydride, CaH_2, reacts with water to form hydrogen gas:

$$CaH_2(s) + 2\,H_2O(l) \longrightarrow Ca(OH)_2(aq) + 2\,H_2(g)$$

This reaction is sometimes used to inflate life rafts, weather balloons, and the like, when a simple, compact means of generating H_2 is desired. How many grams of CaH_2 are needed to generate 145 L of H_2 gas if the pressure of H_2 is 825 torr at 21 °C?

10.57 The metabolic oxidation of glucose, $C_6H_{12}O_6$, in our bodies produces CO_2, which is expelled from our lungs as a gas:

$$C_6H_{12}O_6(aq) + 6\,O_2(g) \longrightarrow 6\,CO_2(g) + 6\,H_2O(l)$$

(**a**) Calculate the volume of dry CO_2 produced at body temperature (37 °C) and 0.970 atm when 24.5 g of glucose is consumed in this reaction. (**b**) Calculate the volume of oxygen you would need, at 1.00 atm and 298 K, to completely oxidize 50.0 g of glucose.

10.58 Both Jacques Charles and Joseph Louis Guy-Lussac were avid balloonists. In his original flight in 1783, Jacques Charles used a balloon that contained approximately 31,150 L of H_2. He generated the H_2 using the reaction between iron and hydrochloric acid:

$$Fe(s) + 2\,HCl(aq) \longrightarrow FeCl_2(aq) + H_2(g)$$

How many kilograms of iron were needed to produce this volume of H_2 if the temperature was 22 °C?

10.59 Hydrogen gas is produced when zinc reacts with sulfuric acid:

$$Zn(s) + H_2SO_4(aq) \longrightarrow ZnSO_4(aq) + H_2(g)$$

If 159 mL of wet H_2 is collected over water at 24 °C and a barometric pressure of 738 torr, how many grams of Zn have been consumed? (The vapor pressure of water is tabulated in Appendix B.)

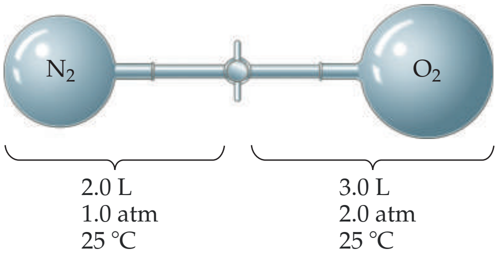
10.60 Acetylene gas, $C_2H_2(g)$, can be prepared by the reaction of calcium carbide with water:

$$CaC_2(s) + 2\,H_2O(l) \longrightarrow Ca(OH)_2(aq) + C_2H_2(g)$$

Calculate the volume of C_2H_2 that is collected over water at 23 °C by reaction of 1.524 g of CaC_2 if the total pressure of the gas is 753 torr. (The vapor pressure of water is tabulated in Appendix B.)

Gas Mixtures and Partial Pressures (Section 10.4)

10.61 Consider the apparatus shown in the following drawing. (**a**) When the valve between the two containers is opened and the gases are allowed to mix, how does the volume occupied by the N_2 gas change? What is the partial pressure of N_2 after mixing? (**b**) How does the volume of the O_2 gas change when the gases mix? What is the partial pressure of O_2 in the mixture? (**c**) What is the total pressure in the container after the gases mix?



10.62 Consider a mixture of two gases, A and B, confined in a closed vessel. A quantity of a third gas, C, is added to the same vessel at the same temperature. How does the addition of gas C affect the following: (**a**) the partial pressure of gas A, (**b**) the total pressure in the vessel, (**c**) the mole fraction of gas B?

10.63 A mixture containing 0.765 mol He(*g*), 0.330 mol Ne(*g*), and 0.110 mol Ar(*g*) is confined in a 10.00-L vessel at 25 °C. (**a**) Calculate the partial pressure of each of the gases in the mixture. (**b**) Calculate the total pressure of the mixture.

10.64 A deep-sea diver uses a gas cylinder with a volume of 10.0 L and a content of 51.2 g of O_2 and 32.6 g of He. Calculate the partial pressure of each gas and the total pressure if the temperature of the gas is 19 °C.

10.65 The atmospheric concentration of CO_2 gas is presently 407 ppm (parts per million, by volume; that is, 407 L of every 10^6 L of the atmosphere are CO_2). What is the mole fraction of CO_2 in the atmosphere?

10.66 A plasma-screen TV contains thousands of tiny cells filled with a mixture of Xe, Ne, and He gases that emits light of specific wavelengths when a voltage is applied. A particular plasma cell, 0.900 mm × 0.300 mm × 10.0 mm, contains Xe, Ne, and He atoms in a ratio of 1:12:12, respectively, at a total pressure of 500 torr at 298 K. Calculate the number of Xe, Ne, and He atoms in the cell.

10.67 A piece of dry ice (solid carbon dioxide) with a mass of 5.50 g is placed in a 10.0-L vessel that already contains air at 705 torr and 24 °C. After the carbon dioxide has totally sublimed, what is the partial pressure of the resultant CO_2 gas, and the total pressure in the container, at 24 °C?

10.68 A sample of 5.00 mL of diethyl ether ($C_2H_5OC_2H_5$, density $= 0.7134\ \mathrm{g/mL}$) is introduced into a 6.00-L vessel that already contains a mixture of N_2 and O_2, whose partial pressures are $P_{N_2} = 0.751$ atm and $P_{O_2} = 0.208$ atm. The temperature is held at 35.0 °C, and the diethyl ether totally evaporates. (**a**) Calculate the partial pressure of the diethyl ether. (**b**) Calculate the total pressure in the container.

10.69 A rigid vessel containing a 3:1 mol ratio of carbon dioxide and water vapor is held at 200 °C where it has a total pressure of 2.00 atm. If the vessel is cooled to 10 °C so that all of the water vapor condenses, what is the pressure of carbon dioxide? Neglect the volume of the liquid water that forms on cooling.

10.70 If 5.15 g of Ag_2O is sealed in a 75.0-mL tube filled with 760 torr of N_2 gas at 32 °C, and the tube is heated to 320 °C, the Ag_2O decomposes to form oxygen and silver. What is the total pressure inside the tube, assuming the volume of the tube remains constant?

10.71 At an underwater depth of 250 ft, the pressure is 8.38 atm. What should the mole percent of oxygen be in the diving gas for the partial pressure of oxygen in the mixture to be 0.21 atm, the same as in air at 1 atm?

10.72 (**a**) What are the mole fractions of each component in a mixture of 15.08 g of O_2, 8.17 g of N_2, and 2.64 g of H_2? (**b**) What is the partial pressure in atm of each component of this mixture if it is held in a 15.50-L vessel at 15 °C?

10.73 A quantity of N_2 gas originally held at 5.25 atm pressure in a 1.00-L container at 26 °C is transferred to a 12.5-L container at 20 °C. A quantity of O_2 gas originally at 5.25 atm and 26 °C in a 5.00-L container is transferred to this same container. What is the total pressure in the new container?

10.74 A sample of 3.00 g of $SO_2(g)$ originally in a 5.00-L vessel at 21 °C is transferred to a 10.0-L vessel at 26 °C. A sample of 2.35 g of $N_2(g)$ originally in a 2.50-L vessel at 20 °C is transferred to this same 10.0-L vessel. (**a**) What is the partial pressure of $SO_2(g)$ in the larger container? (**b**) What is the partial pressure of $N_2(g)$ in this vessel? (**c**) What is the total pressure in the vessel?

Kinetic-Molecular Theory of Gases; Molecular Speeds, Effusion, and Diffusion (Sections 10.5 and 10.6)

10.75 Determine whether each of the following changes will increase, decrease, or not affect the rate with which gas molecules collide with the walls of their container: (**a**) increasing the volume of the container, (**b**) increasing the temperature, (**c**) increasing the molar mass of the gas.

10.76 Indicate which of the following statements regarding the kinetic-molecular theory of gases are correct. (**a**) The average kinetic energy of a collection of gas molecules at a given temperature is proportional to the square root of their mass, $m^{1/2}$. (**b**) The gas molecules are assumed to exert no forces on each other, aside from random elastic collisions. (**c**) All the molecules of a gas at a given temperature have the same kinetic energy. (**d**) The volume of the gas molecules is negligible in comparison to the total volume in which the gas is contained. (**e**) All gas molecules move with the same speed if they are at the same temperature.

10.77 WF_6 is one of the heaviest known gases. How much slower is the root-mean-square speed of WF_6 than He at 300 K?

10.78 You have an evacuated container of fixed volume and known mass and introduce a known mass of a gas sample. Measuring the pressure at constant temperature over time, you are surprised to see it slowly dropping. You measure the mass of the gas-filled container and find that the mass is what it should be—gas plus container—and the mass does not change over time, so you do not have a leak. Suggest an explanation for your observations.

10.79 The temperature of a 5.00-L container of N_2 gas is increased from 20 °C to 250 °C. If the volume is held constant, predict qualitatively how this change affects the following: (**a**) the average kinetic energy of the molecules; (**b**) the root-mean-square speed of the molecules; (**c**) the strength of the impact of an average molecule with the container walls; (**d**) the total number of collisions of molecules with walls per second.

10.80 Suppose you have two 1-L flasks, one containing N_2 at STP, the other containing CH_4 at STP. How do these systems compare with respect to (**a**) number of molecules, (**b**) density, (**c**) average kinetic energy of the molecules, (**d**) rate of effusion through a pinhole leak?

10.81 (**a**) Place the following gases in order of increasing average molecular speed at 25 °C: Ne, HBr, SO_2, NF_3, CO. (**b**) Calculate the rms speed of NF_3 molecules at 25 °C. (**c**) Calculate the most probable speed of an ozone molecule in the stratosphere, where the temperature is 270 K.

10.82 (**a**) Place the following gases in order of increasing average molecular speed at 300 K: CO, SF_6, H_2S, Cl_2, HBr. (**b**) Calculate the rms speeds of CO and Cl_2 molecules at 300 K. (**c**) Calculate the average speeds of CO and Cl_2 molecules at 300 K.

10.83 Which one or more of the following statements are *true*?

(**a**) O_2 will effuse faster than Cl_2.

(**b**) Effusion and diffusion are different names for the same process.

(**c**) Perfume molecules travel to your nose by the process of effusion.

(**d**) The higher the density of a gas, the shorter the mean free path.

10.84 At constant pressure, the mean free path (λ) of a gas molecule is directly proportional to temperature. At constant temperature, λ is inversely proportional to pressure. If you compare two different gas molecules at the same temperature and pressure, λ is inversely proportional to the square of the diameter of the gas molecules. Put these facts together to create a formula for the mean free path of a gas molecule with a proportionality constant (call it R_{mfp}, like the ideal-gas constant) and define units for R_{mfp}.

10.85 Hydrogen has two naturally occurring isotopes, ^1H and ^2H. Chlorine also has two naturally occurring isotopes, ^{35}Cl and ^{37}Cl. Thus, hydrogen chloride gas consists of four distinct types of molecules: $^1H^{35}Cl$, $^1H^{37}Cl$, $^2H^{35}Cl$, and $^2H^{37}Cl$. Place these four molecules in order of increasing rate of effusion.

10.86 The "escape velocity" for an object to escape from the top of Earth's atmosphere is 7.1 km/s. (**a**) At what temperature would the rms speed of a He atom equal this value? (**b**) The actual temperature at the top of the atmosphere is approximately 200 K. Thus, only a small proportion of He atoms at this temperature are moving fast enough to potentially escape from Earth. Calculate the rms speed of a He atom at 200 K. (**c**) Calculate the rms speed of a hydrogen molecule at 200 K. (**d**) Which gas—hydrogen or helium—is more likely to escape Earth's atmosphere?

10.87 Arsenic(III) sulfide sublimes readily, even below its melting point of 320 °C. The molecules of the vapor phase are found to effuse through a tiny hole at 0.28 times the rate of effusion of Ar atoms under the same conditions of temperature and pressure. What is the molecular formula of arsenic(III) sulfide in the gas phase?

10.88 A gas of unknown molecular mass was allowed to effuse through a small opening under constant-pressure conditions. It required 105 s for 1.0 L of the gas to effuse. Under identical experimental conditions it required 31 s for 1.0 L of O_2 gas to effuse. Calculate the molar mass of the unknown gas. (Remember that the faster the rate of effusion, the shorter the time required for effusion of 1.0 L; in other words, rate is the amount that diffuses over the time it takes to diffuse.)

Real Gases: Deviations from Ideal Behavior (Section 10.7)

10.89 (**a**) List two experimental conditions under which gases deviate from ideal behavior. (**b**) List two reasons why the gases deviate from ideal behavior.

10.90 The planet Jupiter has a surface temperature of 140 K and a mass 318 times that of Earth. Mercury (the planet) has a surface temperature between 600 K and 700 K and a mass 0.05 times that of Earth. On which planet is the atmosphere more likely to obey the ideal-gas law?

10.91 Which statement concerning the van der Waals constants *a* and *b* is *true*?

(**a**) The magnitude of *a* relates to molecular volume, whereas *b* relates to attractions between molecules.

(**b**) The magnitude of *a* relates to attractions between molecules, whereas *b* relates to molecular volume.

(**c**) The magnitudes of *a* and *b* depend on pressure.

(**d**) The magnitudes of *a* and *b* depend on temperature.

10.92 Calculate the pressure that CCl_4 will exert at 80 °C if 1.00 mol occupies 33.3 L, assuming that (**a**) CCl_4 obeys the ideal-gas equation; (**b**) CCl_4 obeys the van der Waals equation. (Values for the van der Waals constants are given in Table 10.3.) (**c**) Which would you expect to deviate more from ideal behavior under these conditions, Cl_2 or CCl_4? Explain.

10.93 Table 10.3 shows that the van der Waals *b* parameter has units of L/mol. This implies that we can calculate the size of atoms or molecules from *b*. Using the value of *b* for Xe, calculate the radius of a Xe atom and compare it to the value found in Figure 7.7—that is, 1.40 Å. Recall that the volume of a sphere is $(4/3)\pi r^3$.

10.94 Table 10.3 shows that the van der Waals *b* parameter has units of L/mol. This means that we can calculate the sizes of atoms or molecules from the *b* parameter. Refer back to the discussion in Section 7.3. Is the van der Waals radius we calculate from the *b* parameter of Table 10.3 more closely associated with the bonding or nonbonding atomic radius discussed there? Explain.

Additional Exercises

10.95 A gas bubble with a volume of 1.0 mm^3 originates at the bottom of a lake where the pressure is 3.0 atm. Calculate its volume when the bubble reaches the surface of the lake where the pressure is 730 torr, assuming that the temperature doesn't change.

10.96 A 15.0-L tank is filled with helium gas at a pressure of 1.00×10^2 atm. How many balloons (each 2.00 L) can be inflated to a pressure of 1.00 atm, assuming that the temperature remains constant and that the tank cannot be emptied below 1.00 atm?

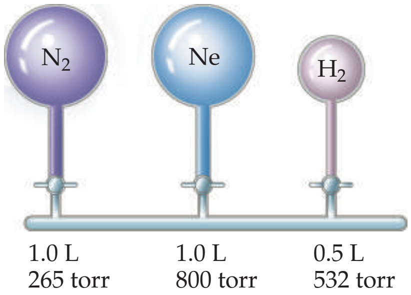
10.97 To minimize the rate of evaporation of the tungsten filament, 1.4×10^{-5} mol of argon is placed in a 600-cm^3 light bulb. What is the pressure of argon in the light bulb at 23 °C?

10.98 Carbon dioxide, which is recognized as the major contributor to global warming as a "greenhouse gas," is formed when fossil fuels are combusted, as in electrical power plants fueled by coal, oil, or natural gas. One potential way to reduce the amount of CO_2 added to the atmosphere is to store it as a compressed gas in underground formations. Consider a 1000-megawatt coal-fired power plant that produces about 6×10^6 tons of CO_2 per year. (**a**) Assuming ideal-gas behavior, 1.00 atm, and 27 °C, calculate the volume of CO_2 produced by this power plant. (**b**) If the CO_2 is stored underground as a liquid at 10 °C and 120 atm and a density of 1.2 g/cm^3, what volume does it possess? (**c**) If it is stored underground as a gas at 30 °C and 70 atm, what volume does it occupy?

10.99 Nickel carbonyl, $Ni(CO)_4$, is one of the most toxic substances known. The present maximum allowable concentration in laboratory air during an 8-h workday is 1 ppb (parts per billion) by volume, which means that there is one mole of $Ni(CO)_4$ for every 10^9 moles of gas. Assume 24 °C and 1.00 atm pressure. What mass of $Ni(CO)_4$ is allowable in a laboratory room that is 12 ft × 20 ft × 9 ft?

10.100 When a large evacuated flask is filled with argon gas, its mass increases by 3.224 g. When the same flask is again evacuated and then filled with a gas of unknown molar mass, the mass increase is 8.102 g. (**a**) Based on the molar mass of argon, estimate the molar mass of the unknown gas. (**b**) What assumptions did you make in arriving at your answer?

10.101 Consider the arrangement of bulbs shown in the drawing. Each of the bulbs contains a gas at the pressure shown. What is the pressure of the system when all the stopcocks are opened, assuming that the temperature remains constant? (We can neglect the volume of the capillary tubing connecting the bulbs.)

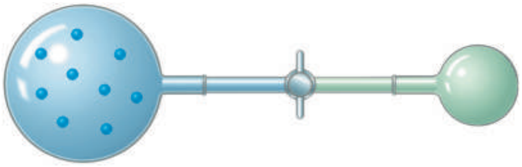


10.102 Assume that a single cylinder of an automobile engine has a volume of 524 cm^3. (**a**) If the cylinder is full of air at 74 °C and 0.980 atm, how many moles of O_2 are present? (The mole fraction of O_2 in dry air is 0.2095.) (**b**) How many grams of C_8H_{18} could be combusted by this quantity of O_2, assuming complete combustion with formation of CO_2 and H_2O?

10.103 Assume that an exhaled breath of air consists of 74.8% N_2, 15.3% O_2, 3.7% CO_2, and 6.2% water vapor. (**a**) If the total pressure of the gases is 0.985 atm, calculate the partial pressure of each component of the mixture. (**b**) If the volume of the exhaled gas is 455 mL and its temperature is 37 °C, calculate the number of moles of CO_2 exhaled. (**c**) How many grams of glucose ($C_6H_{12}O_6$) would need to be metabolized to produce this quantity of CO_2? (The chemical reaction is the same as that for combustion of $C_6H_{12}O_6$. See Section 3.2 and Problem 10.57.)

10.104 A 1.42-g sample of helium and an unknown mass of O_2 are mixed in a flask at room temperature. The partial pressure of the helium is 42.5 torr, and that of the oxygen is 158 torr. What is the mass of the oxygen?

10.105 An ideal gas at a pressure of 1.50 atm is contained in a bulb of unknown volume. A stopcock is used to connect this bulb with a previously evacuated bulb that has a volume of 0.800 L as shown here. When the stopcock is opened, the gas expands into the empty bulb. If the temperature is held constant during this process and the final pressure is 695 torr, what is the volume of the bulb that was originally filled with gas?



10.106 You have a sample of gas at −33 °C. You wish to increase the rms speed by a factor of 2. To what temperature should the gas be heated?

10.107 Consider the following gases, all at STP: Ne, SF_6, N_2, CH_4. (**a**) Which gas is most likely to depart from the assumption of the kinetic-molecular theory that says there are no attractive or repulsive forces between molecules? (**b**) Which one is closest to an ideal gas in its behavior? (**c**) Which one has the highest root-mean-square molecular speed at a given temperature? (**d**) Which one has the highest total molecular volume relative to the space occupied by the gas? (**e**) Which has the highest average kinetic-molecular energy? (**f**) Which one would effuse more rapidly than N_2? **(g)** Which one would have the largest van der Waals *b* parameter?

10.108 Does the effect of intermolecular attraction on the properties of a gas become more significant or less significant if (**a**) the gas is compressed to a smaller volume at constant temperature; (**b**) the temperature of the gas is increased at constant volume?

10.109 Large amounts of nitrogen gas are used in the manufacture of ammonia, principally for use in fertilizers. Suppose 120.00 kg of $N_2(g)$ is stored in a 1100.0-L metal cylinder at 280 °C. (**a**) Calculate the pressure of the gas, assuming ideal-gas behavior. (**b**) By using the data in Table 10.3, calculate the pressure of the gas according to the van der Waals equation. (**c**) Under the conditions of this problem, which correction dominates, the one for finite volume of gas molecules or the one for attractive interactions?

10.110 Cyclopropane, a gas used with oxygen as a general anesthetic, is composed of 85.7% C and 14.3% H by mass. (**a**) If 1.56 g of cyclopropane has a volume of 1.00 L at 0.984 atm and 50.0 °C, what is the molecular formula of cyclopropane? (**b**) Judging from its molecular formula, would you expect cyclopropane to deviate more or less than Ar from ideal-gas behavior at moderately high pressures and room temperature? Explain. (**c**) Would cyclopropane effuse through a pinhole faster or more slowly than methane, CH_4?

10.111 Consider the combustion reaction between 25.0 mL of liquid methanol (density = 0.850 g/mL) and 12.5 L of oxygen gas measured at STP. The products of the reaction are $CO_2(g)$ and $H_2O(g)$. Calculate the volume of liquid H_2O formed if the reaction goes to completion and you condense the water vapor.

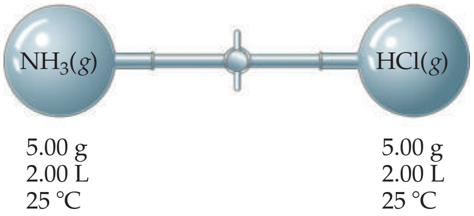
10.112 An herbicide is found to contain only C, H, N, and Cl. The complete combustion of a 100.0-mg sample of the herbicide in excess oxygen produces 83.16 mL of CO_2 and 73.30 mL of H_2O vapor expressed at STP. A separate analysis shows that the sample also contains 16.44 mg of Cl. (**a**) Determine the percentage of the composition of the substance. (**b**) Calculate its empirical formula. (**c**) What other information would you need to know about this compound to calculate its true molecular formula?

10.113 A 4.00-g sample of a mixture of CaO and BaO is placed in a 1.00-L vessel containing CO_2 gas at a pressure of 730 torr and a temperature of 25 °C. The CO_2 reacts with the CaO and BaO, forming $CaCO_3$ and $BaCO_3$. When the reaction is complete, the pressure of the remaining CO_2 is 150 torr. (**a**) Calculate the number of moles of CO_2 that have reacted. (**b**) Calculate the mass percentage of CaO in the mixture.

10.114 Ammonia and hydrogen chloride react to form solid ammonium chloride:

$$NH_3(g) + HCl(g) \longrightarrow NH_4Cl(s)$$

Two 2.00-L flasks at 25 °C are connected by a valve, as shown in the drawing. One flask contains 5.00 g of $NH_3(g)$, and the other contains 5.00 g of $HCl(g)$. When the valve is opened, the gases react until one is completely consumed. (**a**) Which gas will remain in the system after the reaction is complete? (**b**) What will be the final pressure of the system after the reaction is complete? (Neglect the volume of the ammonium chloride formed.) (**c**) What mass of ammonium chloride will be formed?



10.115 Gas pipelines are used to deliver natural gas (methane, CH_4) to the various regions of the United States. The total volume of natural gas that is delivered is on the order of 2.7×10^{12} L per day, measured at STP. Calculate the total enthalpy change for combustion of this quantity of methane. (*Note:* Less than this amount of methane is actually combusted daily. Some of the delivered gas is passed through to other regions.)

10.116 Natural gas is very abundant in many Middle Eastern oil fields. However, the costs of shipping the gas to markets in other parts of the world are high because it is necessary to liquefy the gas, which is mainly methane and has a boiling point at atmospheric pressure of −164 °C. One possible strategy is to oxidize the methane to methanol, CH_3OH, which has a boiling point of 65 °C and can therefore be shipped more readily. Suppose that 10.7×10^9 ft^3 of methane at atmospheric pressure and 25 °C is oxidized to methanol. (**a**) What volume of methanol is formed if the density of CH_3OH is 0.791 g/mL? (**b**) Write balanced chemical equations for the oxidations of methane and methanol to $CO_2(g)$ and $H_2O(l)$. Calculate the total enthalpy change for complete combustion of the 10.7×10^9 ft^3 of methane just described and for complete combustion of the equivalent amount of methanol, as calculated in part (**a**). (**c**) Methane, when liquefied, has a density of 0.466 g/mL; the density of methanol at 25 °C is 0.791 g/mL. Compare the enthalpy change upon combustion of a unit volume of liquid methane and liquid methanol. From the standpoint of energy production, which substance has the higher enthalpy of combustion per unit volume?

10.117 Gaseous iodine pentafluoride, IF_5, can be prepared by the reaction of solid iodine and gaseous fluorine:

$$I_2(s) + 5\,F_2(g) \longrightarrow 2\,IF_5(g)$$

A 5.00-L flask containing 10.0 g of I_2 is charged with 10.0 g of F_2, and the reaction proceeds until one of the reagents is completely consumed. After the reaction is complete, the temperature in the flask is 125 °C. (**a**) What is the partial pressure of IF_5 in the flask? (**b**) What is the mole fraction of IF_5 in the flask (**c**) Draw the Lewis structure of IF_5. (**d**) What is the total mass of reactants and products in the flask?

10.118 A 6.53-g sample of a mixture of magnesium carbonate and calcium carbonate is treated with excess hydrochloric acid. The resulting reaction produces 1.72 L of carbon dioxide gas at 28 °C and 743 torr pressure. (**a**) Write balanced chemical equations for the reactions that occur between hydrochloric acid and each component of the mixture. (**b**) Calculate the total number of moles of carbon dioxide that forms from these reactions. **(c)** Assuming that the reactions are complete, calculate the percentage by mass of magnesium carbonate in the mixture.

Design an Experiment

You are given a cylinder of an unknown, nonradioactive, noble gas and tasked to determine its molar mass and use that value to identify the gas. The tools available to you are several empty mylar balloons that are about the size of a grapefruit when inflated (gases diffuse through mylar much more slowly than conventional latex balloons), an analytical balance, and three graduated glass beakers of different sizes (100 mL, 500 mL, and 2 L). (**a**) To how many significant figures would you need to determine the molar mass to identify the gas? (**b**) Propose an experiment or series of experiments that would allow you to determine the molar mass of the unknown gas. Describe the tools, calculations, and assumptions you would need to use. (**c**) If you had access to a broader range of analytical instruments, describe an alternative way you could identify the gas using any experimental methods that you have learned about in the previous chapters.

11

LIQUIDS AND INTERMOLECULAR FORCES

▲ **SOME LIQUIDS FLOW EASILY FROM ONE CONTAINER TO ANOTHER, WHILE OTHERS LIKE HONEY FLOW VERY SLOWLY.** This property, called viscosity, depends on the strength of the attractive forces between neighboring molecules.

When studying gases, we were able to largely ignore attractive forces between molecules, but this is not the case for liquids and solids, phases whose very existence depends on these forces. To understand the behavior of liquids and solids, we must first understand **intermolecular forces**, the forces that exist *between* molecules. Only by understanding the nature and strength of these forces can we understand how the composition and structure of a substance are related to its physical properties in the liquid and solid states. In this chapter we consider intermolecular forces and how they are related to the properties of liquids, with a focus that is largely on molecular substances. The structures and properties of solids are covered in Chapter 12, where we examine substances with extended bonding networks (ionic, metallic, and network-covalent solids) in addition to molecular substances.

WHAT'S AHEAD

11.1 ▶ A Molecular Comparison of Gases, Liquids, and Solids Compare solids, liquids, and gases from a molecular perspective. Temperature and *intermolecular forces* play critical roles in determining the physical state of a substance.

11.2 ▶ Intermolecular Forces Examine the four intermolecular forces: *dispersion forces*, *dipole–dipole interactions*, *hydrogen bonds*, and *ion–dipole forces*.

11.3 ▶ Select Properties of Liquids Learn how the *viscosity* and *surface tension* of liquids is governed by intermolecular forces.

11.4 ▶ Phase Changes Explore *phase changes*—the transitions of matter between the gaseous, liquid, and solid states—and their associated energies.

11.5 ▶ Vapor Pressure Realize that a dynamic equilibrium exists between the liquid state of a substance and its gaseous state, giving rise to a *vapor pressure* that can be measured.

11.6 ▶ Phase Diagrams Learn how to read *phase diagrams*, which are graphic representations of the equilibria among the gas, liquid, and solid phases.

11.7 ▶ Liquid Crystals Recognize that a substance in the liquid crystalline phase has some aspects of structural order in common with a crystalline solid and yet retains some of the freedom of motion of a liquid.

11.1 | A Molecular Comparison of Gases, Liquids, and Solids

Learning Objectives

When you finish Section 11.1, you should be able to:

- Compare and contrast the behavior of gases, liquids, and solids.
- Explain how the balance between the kinetic energy of atoms, ions, or molecules and the strength of the intermolecular attractions determine the physical state (solid, liquid, gas) of a substance.

As we learned in Chapter 10, the molecules in a gas are widely separated and in a state of constant, chaotic motion. A key tenet of the kinetic-molecular theory of gases is the assumption that we can neglect the interactions between molecules. (Section 10.7) The properties of liquids and solids are quite different from those of gases largely because the intermolecular forces in liquids and solids are much stronger. The properties of gases, liquids, and solids are compared in **Table 11.1**.

In liquids, the intermolecular attractive forces are strong enough to hold particles close together. Thus, liquids are much denser and far less compressible than gases. Unlike gases, liquids have a definite volume, independent of the size and shape of their container. The attractive forces in liquids are not strong enough, however, to keep the particles from moving past one another. Thus, any liquid can be poured and assumes the shape of the container it occupies.

Increasing pressure or decreasing temperature will eventually lock particles in a crystalline arrangement.* This makes solids rigid, in which case their shape and volume are independent of their container. Solids, like liquids, are not very compressible because the particles have little free space between them. Because the particles in a solid or liquid are fairly close together compared with those of a gas, we often refer to solids and liquids as *condensed phases*.

Figure 11.1 compares the three states of matter. *The state of a substance depends largely on the balance between the kinetic energies of the particles (atoms, molecules, or ions) and the interparticle energies of attraction*. The kinetic energies, which depend on temperature, tend to keep the particles apart and moving. The interparticle attractions tend to draw the particles together. Substances that are gases at room temperature have much weaker interparticle attractions than those that are liquids; substances that are liquids have weaker interparticle attractions than those that are solids. The different states of matter adopted by the halogens at room temperature—iodine is a solid, bromine is a liquid, and chlorine is a gas—are a direct consequence of a decrease in the strength of the intermolecular forces as we move from I_2 to Br_2 to Cl_2.

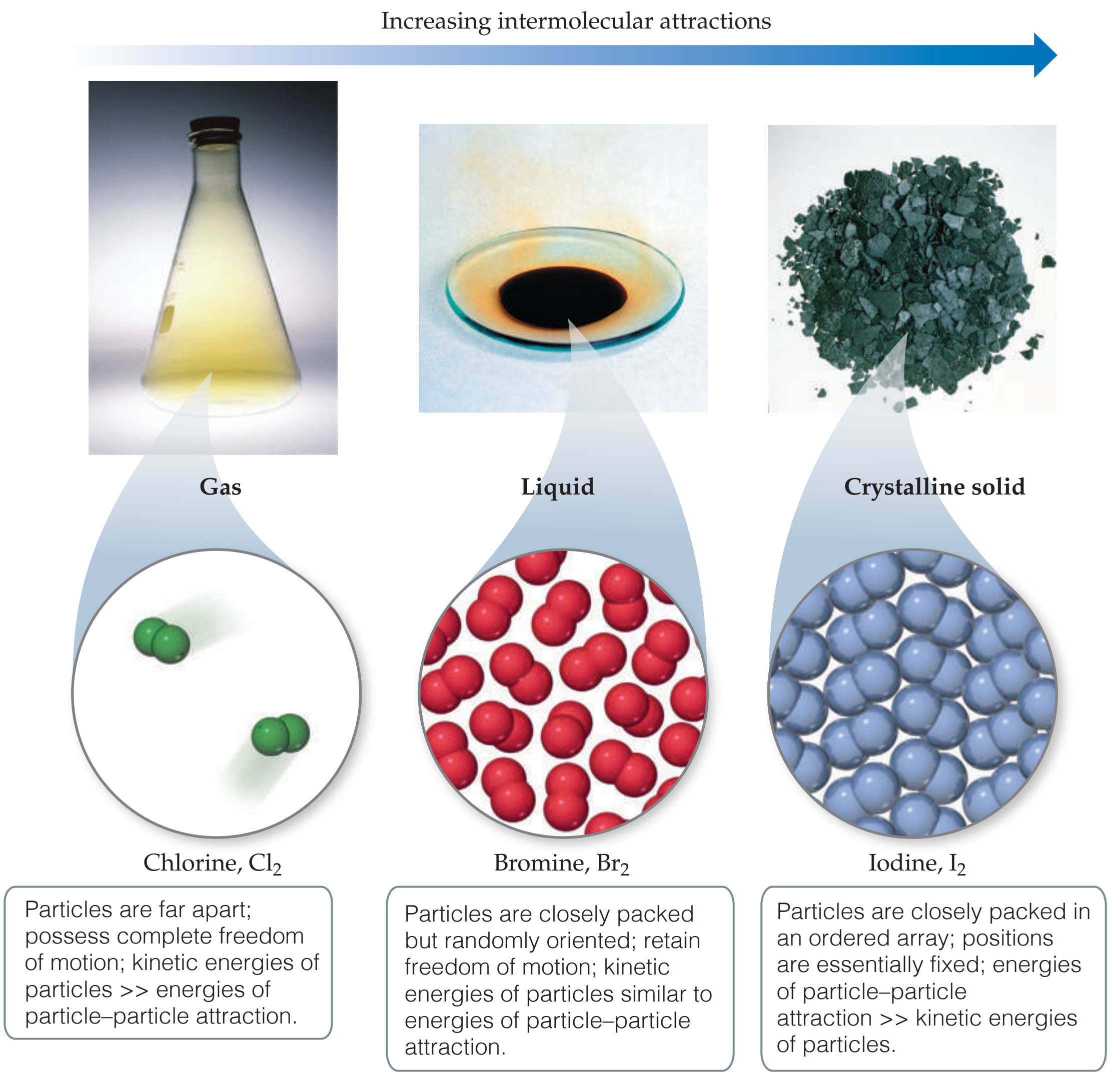
We can change a substance from one state to another by heating or cooling, which changes the average kinetic energy of the particles. NaCl, for example, a solid at room temperature, melts at 1074 K and boils at 1686 K under 1 atm pressure, and Cl_2, a gas at room temperature, liquefies at 239 K and solidifies at 172 K under 1 atm pressure. As the temperature of a gas decreases, the average kinetic energy of its particles decreases, allowing the attractions between the particles to draw the particles close together, forming a liquid, and then to virtually lock them in place, forming a solid. Increasing the pressure on a gas can also drive transformations from gas to liquid to solid because the increased pressure brings the molecules closer together, thus making intermolecular forces more effective. For example, propane (C_3H_8) is a gas at room temperature and 1 atm pressure, whereas liquefied propane (LP) is a liquid at room temperature because it is stored under much higher pressure.

TABLE 11.1 Characteristic Properties of the States of Matter

Gas	Liquid	Solid
Assumes both volume and shape of its container	Assumes shape of a portion of the container it occupies	Retains its own shape and volume
Expands to fill its container	Does not expand to fill its container	Does not expand to fill its container
Is compressible	Is virtually incompressible	Is virtually incompressible
Flows readily	Flows readily	Does not flow
Diffusion within a gas occurs rapidly	Diffusion within a liquid occurs slowly	Diffusion within a solid occurs extremely slowly

---

*The atoms in a solid are able to vibrate in place, which are small motions compared to the molecular motion in gases and liquids. As the temperature of the solid increases, the vibrational motion increases.



Increasing intermolecular attractions
Gas
Liquid
Crystalline solid
Chlorine, Cl_2
Bromine, Br_2
Iodine, I_2
Particles are far apart; possess complete freedom of motion; kinetic energies of particles >> energies of particle–particle attraction.
Particles are closely packed but randomly oriented; retain freedom of motion; kinetic energies of particles similar to energies of particle–particle attraction.
Particles are closely packed in an ordered array; positions are essentially fixed; energies of particle–particle attraction >> kinetic energies of particles.

▲ **Figure 11.1** **Gases, liquids, and solids.** Chlorine, bromine, and iodine are all diatomic molecules as a result of covalent bonding. However, due to differences in the strength of the intermolecular forces, they exist in three different states at room temperature and standard pressure: Cl_2 is a gas, Br_2 is a liquid, and I_2 is a solid.

Self-Assessment Exercises

SAE 11.1 Which characteristic of a liquid is more like a gas than a solid? (**a**) its compressibility (**b**) its density (**c**) its ability to flow (**d**) its molar volume at standard temperature and pressure

SAE 11.2 Substance A is a liquid at room temperature and pressure, while substance B is a gas under the same conditions. Both are molecular substances. Based on this observation, we can say that the intermolecular attractions in substance A are ________ those in substance B. (**a**) stronger than (**b**) weaker than (**c**) approximately the same strength as (**d**) There is insufficient information to decide.

11.2 | Intermolecular Forces

The strengths of *intermolecular* forces vary over a wide range but are generally much weaker than *intramolecular* forces—ionic, metallic, or covalent bonds (**Figure 11.2**). Less energy, therefore, is required to vaporize a liquid or melt a solid than to break covalent bonds. For example, only 16 kJ/mol is required to overcome the intermolecular attractions in liquid HCl to vaporize it. In contrast, the energy required to break the covalent bond in HCl is

Learning Objectives

When you finish Section 11.2, you should be able to:

- Describe what is meant by the polarizability of a molecule and how it leads to intermolecular dispersion forces.
- Compare the relative strengths of dispersion forces in pure substances.
- Compare the relative strengths of dipole–dipole and ion–dipole interactions in pure substances and mixtures.
- Identify hydrogen-bonding interactions and describe how they affect the physical properties of those substances and mixtures in which they occur.
- Compare the relative strength of the intermolecular forces in pure substances and/or mixtures that feature differing intermolecular forces.

Go Figure

How would you expect the H—Cl distance represented by the red dotted line to compare with the H—Cl distance within the HCl molecule?

Cl
H
Cl
Weak intermolecular attraction

▲ **Figure 11.2 Intermolecular and intramolecular interactions.**

431 kJ/mol. Thus, when a molecular substance such as HCl changes from solid to liquid to gas, the molecules remain intact.

Many properties of liquids, including boiling points, reflect the strength of the intermolecular forces. A liquid boils when bubbles of its vapor form within the liquid. The molecules of the liquid must overcome their attractive forces to separate and form a vapor. The stronger the attractive forces, the higher the temperature at which the liquid boils. Similarly, the melting points of solids increase as the strengths of the intermolecular forces increase. As shown in **Table 11.2**, the melting and boiling points of substances in which the particles are held together by chemical bonds tend to be much higher than those of substances in which the particles are held together by intermolecular forces.

Three types of intermolecular attractions exist between electrically neutral molecules: dispersion forces, dipole–dipole attractions, and hydrogen bonding. The first two are collectively called *van der Waals forces* after Johannes van der Waals (1837–1923), who developed the equation for predicting the deviation of gases from ideal behavior. (Section 10.9) Another kind of attractive force, the ion–dipole force, is operative when ions are in close proximity to polar molecules. It plays an important role in the formation and behavior solutions of ionic compounds.

All intermolecular interactions are electrostatic, involving attractions between positive and negative species, much like ionic bonds. (Section 8.2) Why then are intermolecular forces so much weaker than ionic bonds? Recall from Equation 8.4 that electrostatic interactions get stronger as the magnitude of the charges increases and weaker as the distance between charges increases. The charges responsible for intermolecular forces are generally much smaller than the charges in ionic compounds. For example, from its dipole moment it is possible to estimate charges of +0.178 and −0.178 for the hydrogen and chlorine ends of the HCl molecule, respectively (see Sample Exercise 8.5). Furthermore, the distances between molecules are often larger than the distances between atoms held together by chemical bonds.

Dispersion Forces

You might think there would be no electrostatic interactions between electrically neutral, nonpolar atoms and/or molecules. Yet some kind of attractive interactions must exist because nonpolar gases like helium, argon, and nitrogen can be liquefied. Fritz London, a German-American physicist, first proposed the origin of this attraction in 1930. London recognized that the motion of electrons in an atom or molecule can create an *instantaneous,* or momentary, dipole moment.

In a collection of helium atoms, for example, the *average* distribution of the electrons about each nucleus is spherically symmetrical, as shown in **Figure 11.3**(**a**). The atoms are nonpolar and so possess no permanent dipole moment. The *instantaneous* distribution of the electrons, however, can be different from the average distribution. If we could freeze the motion of the electrons at any given instant, both electrons could be on one side of the nucleus. At just that instant, the atom has an instantaneous dipole moment as shown in Figure 11.3(**b**). The motions of electrons in one atom influence the motions of electrons in its neighbors. The instantaneous dipole on one atom can induce

TABLE 11.2 Melting and Boiling Points of Representative Substances

Force Holding Particles Together	Substance	Melting Point (K)	Boiling Point (K)
Chemical bonds			
Ionic bonds	Lithium fluoride (LiF)	1118	1949
Metallic bonds	Beryllium (Be)	1560	2742

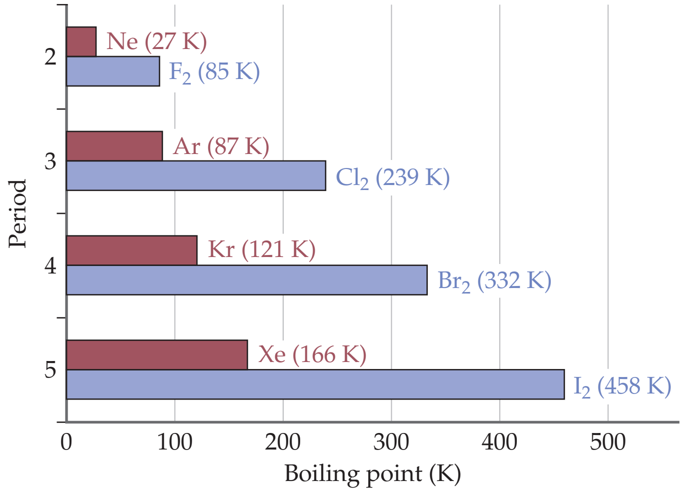
▲ **Figure 11.3** **Dispersion forces.** "Snapshots" of the charge distribution for a pair of helium atoms at three instants.

an instantaneous dipole on an adjacent atom, causing the atoms to be attracted to each other as shown in Figure 11.3(**c**). This attractive interaction is called the **dispersion force** (also called *London dispersion forces* or *induced dipole–induced dipole interactions*). It is significant only when molecules are very close together.

The strength of the dispersion force depends on the ease with which the charge distribution in a molecule can be distorted to induce an instantaneous dipole. The ease with which the charge distribution is distorted is called the molecule's **polarizability**. We can think of the polarizability of a molecule as a measure of the "squashiness" of its electron cloud: The greater the polarizability, the more easily the electron cloud can be distorted to give an instantaneous dipole. Therefore, more polarizable molecules have larger dispersion forces.

In general, polarizability increases as the number of electrons in an atom or molecule increases and as the volume over which the electrons are distributed increases. Because the number of electrons in a molecule and molecular weight generally parallel each other, *dispersion forces tend to increase in strength with increasing molecular weight*. We can see this in the boiling points of the halogens and noble gases (**Figure 11.4**), where dispersion forces

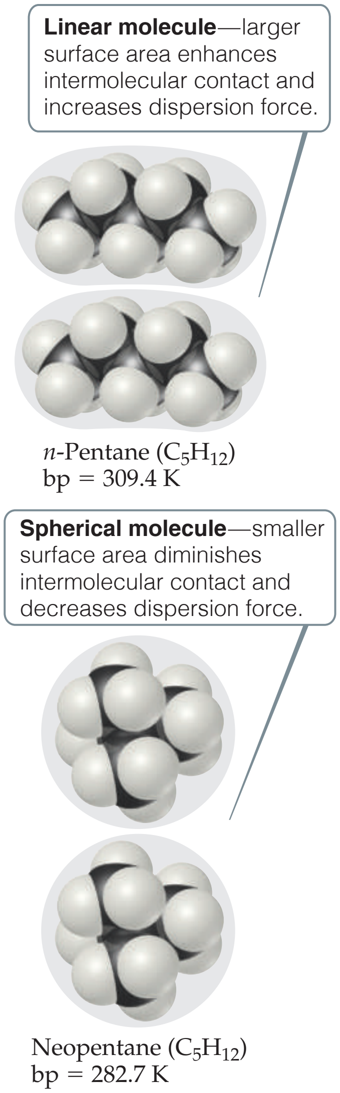
Go Figure Why is the boiling point of the halogen always greater than the corresponding noble gas from the same period?



▲ **Figure 11.4** **Comparing the boiling points of the halogens and noble gases.** This plot shows how the boiling points increase due to stronger dispersion forces as the atomic/molecular weight increases.

are the only intermolecular forces at work. In both families, the atomic/molecular weight increases on moving down the periodic table. The higher atomic/molecular weights translate into stronger dispersion forces, which in turn lead to higher boiling points. If molecules have a similar number of electrons, then larger molecules tend to have stronger dispersion forces. For example, Kr (AW = 83 amu, boiling point = 121 K) has a lower boiling point than Cl_2 (MW = 71 amu, boiling point = 239 K), which has a lower boiling point than *n*-pentane,* C_5H_{12} (MW = 72 amu, boiling point = 309 K).

Molecular shape also influences the magnitude of dispersion forces. For example, *n*-pentane and neopentane (**Figure 11.5**) have the same molecular formula (C_5H_{12}), yet the boiling point of *n*-pentane is about 27 K higher than that of neopentane. The difference can be traced to the different shapes of the two molecules. Intermolecular attraction is greater for *n*-pentane because the molecules can come in contact over the entire length of the long, somewhat cylindrical molecules. Less contact is possible between the more compact and nearly spherical neopentane molecules.



Linear molecule—larger surface area enhances intermolecular contact and increases dispersion force.
n-Pentane (C_5H_{12})
bp = 309.4 K
Spherical molecule—smaller surface area diminishes intermolecular contact and decreases dispersion force.
Neopentane (C_5H_{12})
bp = 282.7 K

▲ **Figure 11.5 Molecular shape affects intermolecular attraction.** Molecules of *n*-pentane make more contact with each other than do neopentane molecules. Therefore, *n*-pentane has stronger intermolecular attractive forces and a higher boiling point.

Dipole–Dipole Interactions

The presence of a permanent dipole moment in polar molecules gives rise to **dipole–dipole interactions**. These interactions originate from electrostatic attractions between the partially positive end of one molecule and the partially negative end of a neighboring molecule. Repulsions can also occur when the positive (or negative) ends of two molecules are in close proximity. Dipole–dipole interactions are effective only when molecules are very close together.

To see the effect of dipole–dipole interactions, we compare the boiling points of two compounds of similar molecular weight: acetonitrile (CH_3CN, MW = 41 amu, boiling point = 355 K) and propane $CH_3CH_2CH_3$, MW = 44 amu, boiling point = 231 K). On the one hand, acetonitrile is a polar molecule, with a dipole moment of 3.9 D, so dipole–dipole interactions are present. Propane, on the other hand, is essentially nonpolar, so dipole–dipole interactions are absent. Because acetonitrile and propane have similar molecular weights, both have similar dispersion forces. Therefore, the higher boiling point of acetonitrile can be attributed to dipole–dipole interactions.

To better understand these forces, compare how CH_3CN molecules pack together in the solid and liquid states. In the solid [**Figure 11.6**(**a**)], the molecules are arranged with the negatively charged nitrogen end of each molecule close to the positively charged $—CH_3$ end of its neighbors. In the liquid [Figure 11.6(**b**)], the molecules are free to move with respect to one another, so their arrangement becomes more disordered. At any given instant, then, both attractive and repulsive dipole–dipole interactions are

present. Nevertheless, the molecular orientations that lead to attractions are greater in number than those that lead to repulsions, so the overall effect is a net attraction strong enough to keep the molecules in liquid CH_3CN from moving apart to form a gas.

For molecules of approximately equal mass and size, the strength of intermolecular attractions increases with increasing polarity, a trend we see in **Figure 11.7**. Notice how the boiling point increases as the dipole moment increases.

▲ **Figure 11.8 Boiling points of the covalent hydrides of the elements in groups 4A–7A as a function of molecular weight.**

group 4A elements (CH_4 through SnH_4, all nonpolar) increase systematically moving down the group. This is the expected trend because polarizability and, hence, dispersion forces generally increase as molecular weight increases. The heavier members of groups 5A, 6A, and 7A follow the same trend, but NH_3, H_2O, and HF have boiling points that are much higher than expected. In fact, these three compounds also have many other characteristics that distinguish them from other substances of similar molecular weight and polarity. For example, water has a high melting point, a high specific heat, and a high heat of vaporization. Each of these properties indicates that the intermolecular forces are abnormally strong.

The strong intermolecular attractions in HF, H_2O, and NH_3 result from *hydrogen bonding. A* ***hydrogen bond*** *is an attraction between a hydrogen atom attached to a highly electronegative atom (usually F, O, or N) and a nearby small electronegative atom in another molecule or chemical group.* Thus, H—F, H—O, or H—N bonds in one molecule can form hydrogen bonds with an F, O, or N atom in another molecule. Several examples of hydrogen bonds are shown in **Figure 11.9**, including the hydrogen bond that exists between the H atom in an H_2O molecule and the O atom of an adjacent H_2O molecule. Notice in each case that the H atom in the hydrogen bond interacts with a nonbonding electron pair.

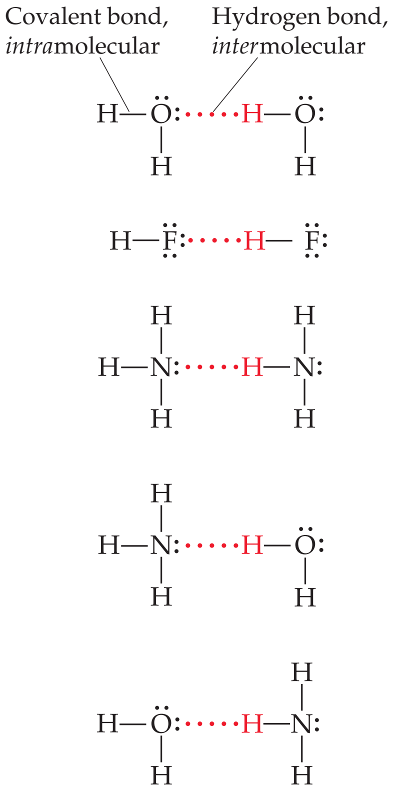
Hydrogen bonds can be considered a special type of dipole–dipole attraction. Because N, O, and F are so electronegative, a bond between hydrogen and any of these elements is quite polar, with hydrogen at the positive end (remember the + on the right-hand side of the dipole symbol represents the positive end and the arrowhead represents the negative end of the dipole):

The hydrogen atom has no inner electrons. Thus, the positive side of the dipole has the concentrated charge of the nearly bare hydrogen nucleus. This positive charge is attracted to the negative charge of an electronegative atom in a nearby molecule. Because the electron-poor hydrogen is so small, it can approach an electronegative atom very closely and, thus, interact strongly with it. The strength of hydrogen bonding generally increases as the electronegativity of the atom covalently bonded to hydrogen increases. As a result, hydrogen bonding in compounds with an O—H bond tends to be stronger than that in comparable compounds with an N—H bond. Hence, methylamine, CH_3NH_2, is a gas under normal conditions, whereas methanol, CH_3OH, is a liquid. Hydrogen bonding is present in both compounds but is stronger in methanol.

Hydrogen bonding plays important roles in many chemical systems, especially those of biological significance. For example, hydrogen bonding helps stabilize the three-dimensional structure of proteins, which is critical to their function. Hydrogen bonding is also responsible for the double-helical structure of DNA, which is key to its genetic function.

Go Figure

To form a hydrogen bond, what must the nonhydrogen atom (N, O, or F) involved in the bond possess?



Covalent bond, *intra*molecular
Hydrogen bond, *inter*molecular

Sample Exercise 11.1

Identifying Substances That Can Form Hydrogen Bonds

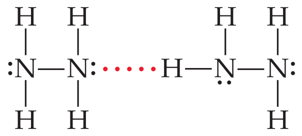
In which of these substances is hydrogen bonding likely to play an important role in determining physical properties: methane (CH_4), hydrazine (H_2NNH_2), methyl fluoride (CH_3F), hydrogen sulfide (H_2S)?

SOLUTION

Analyze We are given the chemical formulas of four compounds and asked to predict whether they can participate in hydrogen bonding. All the compounds contain H, but hydrogen bonding usually occurs only when the hydrogen is covalently bonded to N, O, or F.

Plan We analyze each formula to see if it contains N, O, or F directly bonded to H. There also needs to be a nonbonding pair of electrons on an electronegative atom (usually N, O, or F) in a nearby molecule, which can be revealed by drawing the Lewis structure for the molecule.

Solve The foregoing criteria eliminate CH_4 and H_2S, which do not contain H bonded to N, O, or F. They also eliminate CH_3F, whose Lewis structure shows a central C atom surrounded by three H atoms and an F atom. (Carbon always forms four bonds, whereas hydrogen and fluorine form one each.) Because the molecule contains a C—F bond and not an H—F bond, it does not form hydrogen bonds. In H_2NNH_2, however, we find N—H bonds, and the Lewis structure shows a nonbonding pair of electrons on each N atom, telling us hydrogen bonds can exist between the molecules:



Check Although we can generally identify substances that participate in hydrogen bonding based on their containing N, O, or F covalently bonded to H, drawing the Lewis structure for the interaction provides a way to check the prediction.

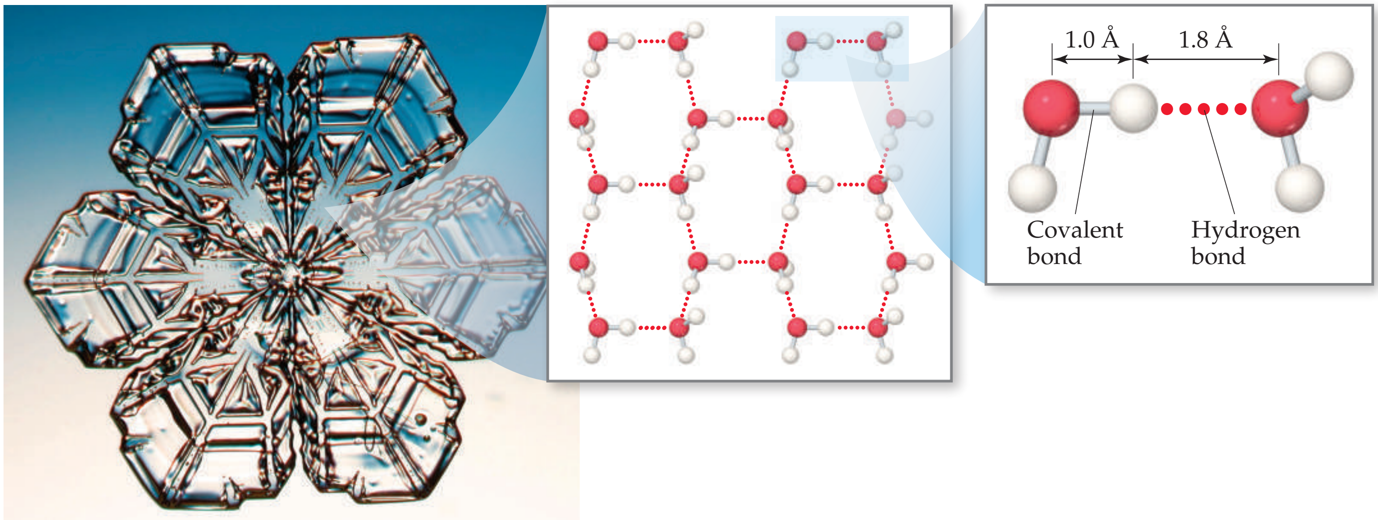
▶ **Practice Exercise**

In which of these substances is significant hydrogen bonding possible: trifluoroethane (CF_3CH_3), phosphine (PH_3), chloramine (NH_2Cl), acetone (CH_3COCH_3)?

One remarkable consequence of hydrogen bonding is seen in the densities of ice and liquid water. In most substances, the molecules in the solid are more densely packed than those in the liquid, making the solid phase denser than the liquid phase. By contrast, the density of ice at 0 °C (0.917 g/mL) is less than that of liquid water at 0 °C (1.00 g/mL), so ice floats on liquid water.

Go Figure

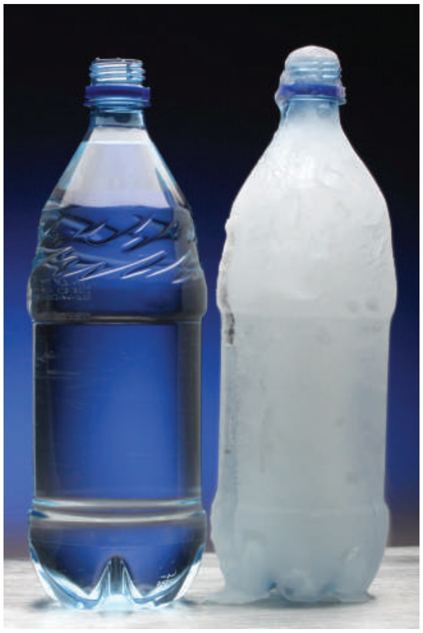
What is the approximate H—O · · · H bond angle in ice, where H—O is the covalent bond and O · · · H is the hydrogen bond?



▲ **Figure 11.10 Hydrogen bonding in ice.** The empty channels in the structure of ice make water less dense as a solid than as a liquid.

The lower density of ice can be understood in terms of hydrogen bonding. In ice, the H_2O molecules assume the ordered, open arrangement shown in **Figure 11.10**. This arrangement optimizes hydrogen bonding between molecules, with each H_2O molecule forming hydrogen bonds to four neighboring H_2O molecules. These hydrogen bonds, however, create the cavities seen in the middle image of Figure 11.10. When ice melts, the motions of the molecules cause the structure to collapse. The hydrogen bonding in the liquid is more random than that in the solid but is strong enough to hold the molecules close together. Consequently, liquid water has a denser structure than ice, meaning that a given mass of water occupies a smaller volume than the same mass of ice.

The expansion of water upon freezing (**Figure 11.11**) is responsible for many phenomena we take for granted. It causes icebergs to float and water pipes to burst in cold weather. The lower density of ice compared to liquid water also profoundly affects life on Earth. Because ice floats, it covers the top of the water when a lake freezes, thereby insulating the water. If ice were denser than water, ice forming at the top of a lake would sink



▲ **Figure 11.11 Expansion of water upon freezing.**

to the bottom, and the lake could freeze solid. Most aquatic life could not survive under these conditions.
